# INSTRUCTIONS TO ABSTRACTORS,

GIVING THE

## NOMENCLATURE AND SYSTEM OF NOTATION

### ADOPTED IN THE ABSTRACTS.

THE object of the abstracts of chemical papers published elsewhere than in the Transactions of the Society is to furnish the Fellows with a concise account of the progress of chemical science from month to month. It must be understood that as the abstracts are prepared for the information of the Fellows in general, they cannot possibly be made so full or so detailed as to obviate on the part of those who are engaged on special investigations the necessity of consulting the original memoirs.

1. Titles of papers must be given literally.
2. Before beginning to write the abstract, the whole of the original paper must be read, in order that a judgment may be formed of its importance and of the scale on which the abstract should be made.
3. In the case of papers dealing with subjects not strictly chemical, the abstract should refer only to matters of chemical interest in the original.
4. The abstract should consist mainly of the expression, in the abstractor's own words, of the substance of the paper.
5. The abstract should be made as short as is consistent with a clear and accurate statement of the author's results.
6. A concise statement showing the general trend of the investigation should be given at the commencement of those abstracts where the nature of the original permits of it.
7. If an abstract of a paper on the same subject, either by the author of the paper abstracted, or by some other author, has already appeared, note should, as a rule, be made of this fact.
8. Matter which has appeared once in the *Abstracts* is not to be abstracted again, a reference being given to the volume in which the abstract may be found.
9. As a rule, details of methods of preparation or analysis, or generally speaking of work, are to be omitted, unless such details are essential to the understanding of the results, or have some independent value. Further, comparatively unimportant compounds, such as the inorganic salts of organic bases or acids, should be mentioned quite shortly. On the other hand, data such as melting and boiling points, sp. gr., specific rotation, &c., must be given in every case unless recorded in earlier papers.

(b) That formulae should be shortened by the judicious employment of the symbols Me for  $\text{CH}_3$ , Et for  $\text{C}_2\text{H}_5$ , Pr<sup>n</sup> for  $\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}_3$ , Pr<sup>s</sup> for  $\text{CH}(\text{CH}_3)_2$ , Ph for  $\text{C}_6\text{H}_5$ , Py for  $\text{C}_5\text{H}_4\text{N}$ , Ac for  $\text{CO}\cdot\text{CH}_3$ , and Bz for  $\text{CO}\cdot\text{C}_6\text{H}_5$ .

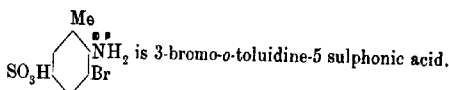

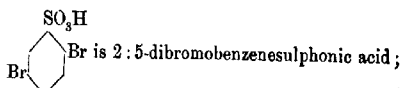

(c) That formulae should be written in *one line* whenever this can be done without obscuring their meaning.

28. In representing the constitution of benzene derivatives, the relative positions of the radicles in the symbol of benzene should be indicated by numerals, instead of by means of the hexagon formula.

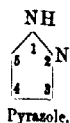

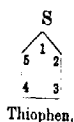

(a) The abbreviations *o*-, *m*-, and *p*-, should be used in place of 1:2- or ortho-, 1:3- or meta-, and 1:4- or para-.

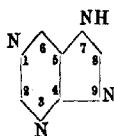

(b) In numbering positions in the case of substitution derivatives of phenol, aniline, benzonitrile, benzoic acid, benzenesulphonic acid, benzaldehyde, and toluene, the characteristic radicle of each of these parent substances is to be regarded as in position 1 (compare Collective Index).

(c) Names of substitution derivatives should be given in such a way that the position of the substituent is indicated by a numeral prefixed; for example:—

29. In representing the constitution of derivatives of other "closed chain" hydrocarbons, graphic formulae should not be employed, but the system of numbering positions indicated in Richter's *Lexikon der Kohlenstoff-Verbindungen* (3rd edition, 1910, pp. 14—26) should be used, of which the following schemes may be regarded as typical:—

Purine.\*

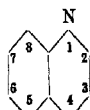

Pyridine.

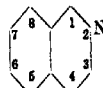

Indole.

Naphthalene.

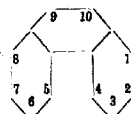

Quinoline.

isoQuinoline.

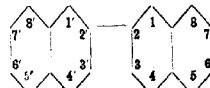

Anthracene.

Phenanthrene.

Diphenyl.

 $\beta$ -Dinaphthyl.**Manuscript.**

30. In view of the difficulty of dealing with MSS. of widely varying sizes, abstracts cannot be accepted unless written on quarto paper (10 x 8 in.).

31. Not more than one abstract must appear on a sheet.

32. When an abstract exceeds a sheet in length, the sheets must be fastened together by means of gum at the top left-hand corner.

33. The name of the abstractor must be written diagonally at the top left-hand corner of the first sheet of the abstract.

**Proofs.**

34. Abstractors are expected to read and correct proofs carefully, and to check all formulae and figures against MSS.

35. All proofs, however small, must be returned to the Sub-Editor not later than 24 hours after receipt from the printers.

\* \* The Editor's decision, in all matters connected with the Abstracts, must be considered final.

\* This numbering, proposed originally by E. Fischer, is adopted in the text of the *Lexikon*.

*List of Symbols Recommended by the Working Committee of the International Commission for the Unification of Physico-chemical Symbols (1914). [See Trans., 1921, 119, 502—512.]*

1. *Mathematical Symbols.*

|  | Usual symbol. | Alternative symbol. |
|--|---------------|---------------------|
| Base of natural (Napierian) logarithms ... | $e$           |                     |
| Diameter .....                             | $d$           |                     |
| Radius .....                               | $r$           |                     |
| Ratio of circumference to diameter .....   | $\pi$         |                     |
| Summation .....                            | $\Sigma$      |                     |
| Variation .....                            | $\delta$      |                     |
| Total differential .....                   | $d$           |                     |
| Partial differential .....                 | $\partial$    |                     |

2. *Universal Constants.*

|   |     |  |
|---|-----|--|
| Acceleration due to gravity .....   | $g$ |  |
| Mechanical equivalent of heat .....   | $J$ |  |
| Avogadro's constant [number of molecules in 1 gram-molecule (mole)] .....   | $N$ |  |
| Gas constant per mole .....   | $R$ |  |
| Faraday's constant (number of coulombs per gram-equivalent of an ion) ..... | $F$ |  |
| Charge on an electron .....   | $e$ |  |

3. *General Physics and Chemistry.*

|   |  |  |
|---|--|--|
| Length .....  | $l$  |  |
| Height .....  | $h$  |  |
| Mass .....  | $m$  |  |
| Time .....  | $t$  |  |
| Volume .....  | $v, V$   |  |
| Density (mass per unit volume) .....  | $d$  |  |
| Pressure .....  | $p, P$   |  |
| Concentration .....   | $c, C$   |  |
| Mole fraction .....   | $x$  |  |
| Critical constants: pressure, volume, temperature (centigrade), temperature (absolute), density ..... | $\left\{ \begin{array}{l} p_c, v_c, \\ t_c, T_c, \\ d_c \end{array} \right.$ |  |
| Reduced quantities: pressure, volume, temperature, density .....                                      | $\left\{ \begin{array}{l} p_r, v_r, \\ t_r, T_r, \\ d_r \end{array} \right.$ |  |
| van der Waals's constants .....   | $a, b$   |  |
| Fluidity .....  | $\phi$   |  |
| Viscosity .....   | $\eta$   |  |
| Surface tension .....   | $\gamma$   |  |
| Diffusion coefficient .....   | $\Delta$   |  |
| Atomic weight .....   | $A$  |  |
| Molecular weight .....  | $M$  |  |
| Velocity coefficient of reaction .....  | $k$  |  |
| Equilibrium constant .....  | $K, (K_c, K_p)$  |  |
| van't Hoff coefficient .....  | $i$  |  |
| Degree of dissociation (electrolytic, thermal, etc.) .....  |  |  |

*D*

## 4. Heat and Thermodynamics.

|  | Usual<br>symbol. | Alternative<br>symbol. |
|--|------------------|------------------------|
| Temperature (centigrade) .....                 | $t$              | $\theta$               |
| Temperature (absolute) .....                   | $T$              |                        |
| Critical temperature .....                     | $t_c, T_c$       |                        |
| Reduced temperature .....                      | $t_r, T_r$       |                        |
| Critical solution temperature .....            | $t_{cs}, T_{cs}$ |                        |
| Quantity of heat .....                         | $Q$              |                        |
| Entropy .....                                  | $S$              |                        |
| Specific heat .....                            | $c$              |                        |
| Specific heat at constant pressure .....       | $c_p$            |                        |
| Specific heat at constant volume .....         | $c_v$            |                        |
| Ratio of specific heats, $c_p : c_v$ .....     | $\gamma$         |                        |
| Molecular heat .....                           | $C$              |                        |
| Molecular heat at constant pressure .....      | $C_p$            |                        |
| Molecular heat at constant volume .....        | $C_v$            |                        |
| Latent heat per gram .....                     | $l$              |                        |
| Latent heat per mole .....                     | $L$              |                        |
| Maximum work (diminution of free energy) ..... | $A$              |                        |

## 5. Optics.

|  |   |  |
|--|---|--|
| Wave-length of light .....                           | $\lambda$   |  |
| Refractive index .....                               | $n$   |  |
| Specific refractive power (Gladstone and Dale) ..... | $\sigma_s, [\sigma_s]_d$  |  |
| Specific refractive power (Lorentz and Lorenz) ..... | $\sigma_L, [\sigma_L]_d$  |  |
| Molecular refractive power .....                     | $\left\{ \begin{array}{l} R_g, R_L \\ [R_g]_d, [R_L]_d \end{array} \right.$ |  |
| Angle of optical rotation .....                      | $\alpha$  |  |
| Specific rotatory power .....                        | $[\alpha]$  |  |
| Molecular rotatory power .....                       | $M[\alpha]$   |  |
| Specific magnetic rotation .....                     | $[\omega]$  |  |
| Molecular magnetic rotation .....                    | $M[\omega]$   |  |

## 6. Electricity and Magnetism.

|   |  |  |
|---|--|--|
| Quantity of electricity .....   | $Q$  |  |
| Current intensity .....   | $I$  |  |
| Resistance .....  | $R$  |  |
| Electromotive force .....   | $E$  |  |
| Electrode potential, or discharge potential of an ion .....   | $E$  |  |
| Electrode potential referred to the normal hydrogen or normal calomel electrode respectively, the potential of which is taken as zero .....   | $E_h, E_c$                                     |  |
| Normal potential, i.e., the electrode potential referred to the normal hydrogen or normal calomel electrode respectively, when the solution is molecular-normal in respect of all participating substances and ions of variable concentration ..... | ${}^nE_h, {}^nE_c$                             |  |
| Dielectric constant .....   | $\epsilon$                                     |  |
| Conductivity (specific conductance) .....   | $\kappa$                                       |  |
| Equivalent conductivity .....   | $\Lambda$                                      |  |
| Equivalent conductivity at different dilutions—volumes in litres containing 1 gram-equivalent .....   | $\Lambda_{10}, \Lambda_{20}, \Lambda_{\infty}$ |  |

## 6. Electricity and Magnetism—(continued).

|  | Usual symbol.          | Alternative symbol. |
|--|------------------------|---------------------|
| Equivalent conductivity of kation and of anion .....   | $\Lambda_k, \Lambda_a$ |                     |
| Equivalent conductivity of specified ions...   | $\Lambda_K, \Lambda_A$ |                     |
| Molecular conductivity .....   | $\mu$                  |                     |
| Velocity of kation and of anion in cm./sec. when the potential gradient is 1 volt per cm. .... | $U_k, U_a$             |                     |
| Transport number of kation and of anion ...  | $n_k, n_a$             |                     |
| Magnetic permeability .....  | $\mu$                  |                     |
| Magnetic susceptibility .....  | $\kappa$               |                     |

*List of Symbols, Arranged Alphabetically.*

| Symbol.            | Name of quantity.   |
|--------------------|---|
| $A$                | Atomic weight; maximum work.  |
| $a$                | Van der Waals's constant.   |
| $b$                | Van der Waals's constant.   |
| $C$                | Concentration; molecular heat.  |
| $c$                | Concentration; specific heat.   |
| $C_p, C_v$         | Molecular heat at constant pressure, and at constant volume.  |
| $c_p, c_v$         | Specific heat at constant pressure, and at constant volume.   |
| $D$                | Alternative symbol for density.   |
| $d$                | Diameter; total differential; density.  |
| $d_c$              | Critical density.   |
| $d_r$              | Reduced density.  |
| $E$                | Electromotive force; electrode potential.   |
| $e$                | Base of Napierian logarithms; charge on an electron.  |
| $E_h, E_s$         | Electrode potential referred to the normal hydrogen or the normal calomel electrode, respectively, the potential of which is taken as zero.   |
| ${}_0E_h, {}_0E_s$ | Normal potential, that is, the electrode potential referred to the normal hydrogen or the normal calomel electrode respectively, when the solution is molecular-normal in respect of all participating substances and ions of variable concentration. |
| $F$                | Faraday's constant (number of coulombs per gram-equivalent of an ion).  |
| $g$                | Acceleration due to gravity.  |
| $h$                | Height.   |
| $I$                | Current.  |
| $i$                | Van't Hoff's coefficient.   |
| $J$                | Mechanical equivalent of heat.  |
| $K$                | Equilibrium constant.   |
| $K_m, K_p$         | Equilibrium constant, when molar concentrations and partial pressures respectively are employed.  |
| $k$                | Velocity coefficient of reaction.   |
| $L$                | Latent heat per mole.   |
| $l$                | Length; latent heat per gram.   |
| $M$                | Molecular weight.   |
| $M[\alpha]$        | Molecular rotatory power.   |
| $M[\omega]$        | Molecular magnetic rotatory power.  |
| $m$                | Mass.   |
| $N$                | Avogadro's constant (Loschmidt's number) or number of molecules in 1 gram-molecule.   |
|                    | Refractive index.   |

*List of Symbols, Arranged Alphabetically—(continued).*

| Symbol.                                     | Name of quantity.   |
|---|---|
| $n_+, n_-$                                  | Transport number of kation and of anion.  |
| $n_r$                                       | Refractive index (alternative symbol).  |
| $P$   | Pressure.   |
| $p$   | Pressure.   |
| $p_0, p_r$                                  | Critical pressure : reduced pressure.   |
| $Q$   | Quantity of heat; quantity of electricity.  |
| $R$   | Gas constant per mole; electrical resistance.   |
| $R_0, R_L$                                  | Molecular refractive power, according to Gladstone and Dale, and to Lorentz and Lorenz respectively.  |
| $r$   | Radius.   |
| $r_0, r_L$                                  | Specific refractive power according to Gladstone and Dale, and to Lorentz and Lorenz respectively.  |
| $S$   | Entropy.  |
| $T$   | Absolute temperature.   |
| $T_c$                                       | Critical temperature (on the absolute scale).   |
| $T_r$                                       | Reduced temperature (absolute).   |
| $T_{cs}$                                    | Critical solution temperature (absolute).   |
| $t$   | Time; temperature (centigrade).   |
| $t_c$                                       | Critical temperature (centigrade).  |
| $t_{cs}$                                    | Critical solution temperature (centigrade).   |
| $t_r$                                       | Reduced temperature (centigrade).   |
| $U_+, U_-$                                  | Velocity of kation and of anion in cm./sec. when the potential gradient is 1 volt per cm.   |
| $V$   | Volume.   |
| $v$   | Volume.   |
| $v_0, v_r$                                  | Critical volume : reduced volume.   |
| $W$   | Electrical resistance (alternative symbol).   |
| $x$   | Mole fraction.  |
| $\alpha$                                    | Degree of dissociation (electrolytic, thermal, etc.); angle of optical rotation.  |
| $[\alpha]$                                  | Specific rotatory power.  |
| $\gamma$                                    | Surface tension; ratio of specific heats.   |
| $\Delta$                                    | Diffusion coefficient.  |
| $\delta$                                    | Variation.  |
| $\partial$                                  | Partial differential.   |
| $\epsilon$                                  | Electrode potential (alternative symbol); dielectric constant.  |
| $\epsilon_+, \epsilon_-$                    | Electrode potential referred to the normal hydrogen or the normal calomel electrode respectively, the potential of which is taken as zero (alternative symbols).  |
| $\epsilon^+, \epsilon^-, \epsilon^0$        | Normal potential, that is, the electrode potential referred to the normal hydrogen or the normal calomel electrode respectively, when the solution is molecular-normal in respect of all participating substances and ions of variable concentration (alternative symbols). |
| $\eta$                                      | Viscosity.  |
| $\theta$                                    | Temperature (centigrade), (alternative symbol).   |
| $\kappa$                                    | Specific conductance (conductivity); magnetic susceptibility.   |
| $\Lambda$                                   | Equivalent conductivity.  |
| $\Lambda_{10}, \Lambda_m, \Lambda_{\infty}$ | Equivalent conductivity at different dilutions (volumes in litres containing 1 gram-equivalent).  |
| $\Lambda_k, \Lambda_a$                      | Equivalent conductivity of kation and of anion.   |
| $\lambda$                                   | Wave-length of light.   |
| $\mu$                                       | Molecular conductivity; magnetic permeability.  |
| $\pi$                                       | Ratio of circumference to diameter.   |
| $\Sigma$                                    | Summation.  |
| $\sigma$                                    | Surface tension (alternative symbol).   |
| $\phi$                                      | Fluidity.   |
| $[\omega]$                                  | Specific magnetic rotation.   |

## JOURNALS FROM WHICH ABSTRACTS ARE MADE.

The following is a list of Journals from which abstracts are made (directly or indirectly) by the Chemical Society and the Society of Chemical Industry. The abbreviated titles printed in italics represent Journals abstracted by the Chemical Society, those printed in roman type being abstracted by the Society of Chemical Industry. Of the former Journals those indicated by an asterisk are also abstracted by the Society of Chemical Industry.

| ABBREVIATED TITLE.  | JOURNAL.   |
|---|--|
| <i>Abh. Böhm. Akad.</i> . . .                                 | Abhandlungen der Böhmischen Akademie.  |
| <i>Abh. Deut. Naturwiss. Med. Ver. Böhmen.</i> . . .          | Abhandlungen der Deutschen Naturwissenschaftlichen und Medizinischen Verein, Böhmen. |
| <i>Acta. Sci. Fennicae</i> . . .                              | Acta Societatis Scientiarum Fennicae.  |
| <i>Agric. Bull. F. M. S.</i> . . .                            | Agricultural Bulletin of the Federated Malay States.                                 |
| <i>Agric. J. India</i> . . .                                  | Agricultural Journal of India.   |
| <i>Agric. Res. Inst., Pusa Rep. (Gull.)</i> . . .             | Agricultural Research Institute, Pusa, Report and Bulletins.                         |
| <i>Allgem. Z. Bierbrau. u. Malzfabr.</i> . . .                | Allgemeine Zeitschrift für Bierbrauerei und Malzfabrikation.                         |
| <i>Amer. J. Bot.</i> . . .                                    | American Journal of Botany.  |
| <i>Amer. J. Dis. Children</i> . . .                           | American Journal of Diseases of Children.  |
| <i>Amer. J. Pharm.</i> . . .                                  | American Journal of Pharmacy.  |
| <i>Amer. J. Physiol.</i> . . .                                | American Journal of Physiology.  |
| <i>Amer. J. Publ. Health</i> . . .                            | American Journal of Public Health.   |
| * <i>Amer. J. Sci.</i> . . .                                  | American Journal of Science.   |
| <i>Amer. Min.</i> . . .                                       | American Mineralogist.   |
| <i>Anal. Asoc. Quím. Argentina</i> . . .                      | Anales de la Asociación Química Argentina.   |
| <i>Anal. Fis. Quím.</i> . . .                                 | Anales de la Sociedad Española de Física y Química.                                  |
| * <i>Analyst</i> . . .  | Analyst.   |
| <i>Annalen</i> . . .  | Justus Liebig's Annalen der Chemie.  |
| <i>Ann. Bot.</i> . . .  | Annals of Botany.  |
| <i>Ann. di Bot.</i> . . .                                     | Annali di Botanica.  |
| <i>Ann. Chim.</i> . . .                                       | Annales de Chimie.   |
| * <i>Ann. Chim. Analyt.</i> . . .                             | Annales de Chimie Analytique et de Chimie Appliquées.                                |
| <i>Ann. di Chim. Appl.</i> . . .                              | Annali di Chimica Applicata.   |
| <i>Ann. Falsif.</i> . . .                                     | Annales des Falsifications.  |
| <i>Ann. hyg. pub. med. legale.</i> . . .                      | Annales d'hygiène publique et de médecine légale.                                    |
| <i>Ann. Inst. Pasteur</i> . . .                               | Annales de l'Institut Pasteur.   |
| <i>Ann. Physik</i> . . .                                      | Annalen der Physik.  |
| <i>Ann. Physique</i> . . .                                    | Annales de Physique.   |
| <i>Ann. R. Staz. Chim. Agrar. Sperim.</i> . . .               | Annali della R. Stazione Chimico Agraria Sperimen tale di Roma.                      |
| <i>Ann. sci. Univ. Jassy</i> . . .                            | Annales scientifiques de l'Université de Jassy.                                      |
| <i>Ann. Soc. Geol. Belg.: Publ. rel. au Congo Belge</i> . . . | Annales de la Société géologique de Belgique: Publications relatives au Congo Belge. |
| <i>Apoth. Zeit.</i> . . .                                     | Apotheker-Zeitung.   |
| <i>Arb. Gebiet. Physik, Math. Chem.</i> . . .                 | Arbeiten aus dem Gebiete der Physik, Mathematik und Chemie.                          |
| <i>Arch. Entw.-mech. Org.</i> . . .                           | Archiv für Entwicklungsmechanik der Organismen.                                      |
| <i>Arch. exp. Path. Pharm.</i> . . .                          | Archiv für experimentelle Pathologie und Pharmakologie.                              |
| <i>Arch. Farm. sperim. Sci. aff.</i> . . .                    | Archivio di Farmacologia sperimentale e Scienze affini.                              |

**Composition of Paraffin Wax.** III. FRANCIS FRANCIS, CYRIL MERCER WATKINS, and REGINALD WILFRED WALLINGTON (T., 1922, 121, 2804—2810).

**Constitution of Squalene.** RIKÔ MAKIMA and BENNOSUKÉ KUBOTA (*Sci. Papers Inst. Phys. Chem. Research*, 1922, 1, 7—21).—Squalene,  $C_{30}H_{50}$ , is a highly unsaturated hydrocarbon isolated from shark's liver oil by Tsujimoto (*J. Chem. Ind. Japan*, 1906, 9, 958; 1917, 20, 953, 1069; A., 1916, i, 786; 1918, i, 89) and may be identical with Chapman's spinacene (T., 1917, 111, 56). The material used was the oil from the liver of *Squalus Mitsukurii*, and had b. p. 284—285°/25 mm.,  $d_4^{20}$  0.8596,  $n_D^{20}$  1.4959. When treated in chloroform solution with oxygen containing 5—7% of ozone, squalene hexaozonide,  $C_{30}H_{50}(O_3)_6$ , was obtained, which suffered decomposition when boiled with water; the products obtained from the ozonide prepared from 27 g. of squalene were as follows: carbon dioxide 1.82 g., formaldehyde undetermined, acetone 1.01 g., acetone peroxide 0.7 g., lævulinaldehyde 0.84 g., formic acid 0.68 g., succinic acid 8.35 g., lævulic acid 9.3 g., an unknown acid,  $C_8H_{14}O_6$ , m. p. 132—134°, 1.5 g., and another unknown acid,  $C_8H_{14}O_6$ , m. p. 191—192°, 0.5 g. From the products of the dry distillation of squalene under atmospheric pressure, isoprene and a colourless liquid, b. p. 62.5—65°/17 mm.,  $d_4^{20}$  0.8208,

VOL. CXXIV. i.

$n_D$  1.4621 (probably cyclodihydroxymyrcene), were isolated. By heating with a mixture of glacial acetic acid and 2% of concentrated sulphuric acid at 65–68° during three hours, squalene was found to be converted into an isomeride containing at least two rings. Further, squalene does not contain conjugated double bonds, and is easily reduced to a dodecahydro-derivative by hydrogen in the presence of platinum black. From these facts, the authors regard squalene as a higher aliphatic terpene, probably a dihydro-triterpene, and suggest the following formula for it as probable, but the nature of the right-hand group,  $\cdot\text{CH}(\text{C}_8\text{H}_{12})\cdot\text{CH}\cdot$ , is still not clear:

K. K.

**Action of Silver Sulphate in Sulphuric Acid Solution on Ethyl Bromide.** E. A. SCHULOV (*Bull. Inst. Polyt. Ivanovo-Voznesensk.*, 1922, 6, 233).—Alcohol is now found (cf. A., 1922, i, 913) among the products of the action of a sulphuric acid solution of silver sulphate on ethyl bromide, so that the ethylsulphuric acid formed evidently undergoes considerable hydrolysis. The conclusion is drawn that the reaction proceeds quantitatively in accordance with the equation  $\text{HAgSO}_4 + \text{EtBr} = \text{AgBr} + \text{EtHSO}_4$ .

T. H. P.

**The Preparation of  $\alpha\delta$ -Dihalogen Derivatives of Butane.** C. S. MARVEL and A. L. TANENBAUM (*J. Amer. Chem. Soc.*, 1922, 44, 2645–2650; cf. von Braun, A., 1907, i, 127).—A good yield of  $\alpha\delta$ -dibromobutane may be obtained by the following series of reactions.  $\alpha\gamma$ -Dibromopropane is converted into  $\gamma$ -phenoxypropyl bromide by the action of sodium phenoxide, and this in turn into phenoxypropyl cyanide by the action of sodium cyanide. This cyanide is hydrolysed by alcoholic sulphuric acid, and the resulting ethyl phenoxybutyrate when reduced by sodium and absolute alcohol in toluene is converted into phenoxybutyl alcohol, b. p. 162–164°/19 mm.,  $n_D^{20}$  1.520, giving a *p*-nitrobenzoate, m. p. 91°. The alcohol, when heated with hydrobromic acid containing a little sulphuric acid, yields a mixture of  $\gamma$ -phenoxybutyl bromide, m. p. 41°, and the required  $\alpha\delta$ -dibromobutane, which may be separated by fractional distillation. In reducing ethyl phenoxybutyrate as described above (cf. Levene and Allen, A., 1917, i, 3), it is essential, if a high yield is to be obtained, to use alcohol that has been distilled first over calcium oxide and then over sodium, and to exclude all traces of moisture during the reduction. This method of reduction was also applied successfully to the reduction of esters of octoic, lauric, and myristic acids to the corresponding alcohols, and also to the reduction of certain cyanides to the corresponding primary amines.

W. G.

**Synthesis of Halogenated Compounds of the Butane Series.** JULIUS VON BRAUN and GEORG LEMKE (*Ber.*, 1922, 55, [B], 3526–3536).— $\alpha\delta$ -Dihalogenated butanes may be prepared conveniently

by oxidising *cyclohexanol* to adipic acid, conversion of the latter into the amide, and thence into the dibenzoyl derivative of  $\alpha\delta$ -aminobutane. Treatment of the latter compounds with phosphorus pentahaloids gives  $\alpha\delta$ -dihalogenobutanes, thus: . . .

The reaction in this case proceeds in exactly the same manner as with the dibenzoyl derivative of  $\alpha\epsilon$ -pentamethylenediamine and its higher homologues.

The oxidation of *cyclohexanol* to adipic acid (cf. Mannich and Hăncu, A., 1908, i, 245) is conveniently effected by the gradual addition of finely-divided potassium permanganate to a well-stirred suspension of *cyclohexanol* in aqueous sodium carbonate solution at 15–30°, the yield of acid being 70% of that theoretically possible. The acid is transformed by thionyl chloride at the atmospheric temperature into the corresponding chloride, which is converted by ammonia into the amide (yield 90%). The latter is converted by bromine and sodium hydroxide into  $\alpha\delta$ -diaminobutane, which, without being isolated, is further converted into the dibenzoyl derivative, m. p. 176–177°, the yield being 60%. Phosphorus pentabromide transforms the latter into  $\alpha\delta$ -dibromobutane, b. p. 80–82°/14 mm., in 70% yield. The similar action of phosphorus pentachloride gives a mixture of  $\alpha\delta$ -dichlorobutane and  $\delta$ -chlorobutylbenzamide,  $\text{Cl}[(\text{CH}_2)_4\cdot\text{NHBz}]$ , m. p. 54–55°.

$\alpha\delta$ -Dibromobutane reacts energetically with bromine in the presence of iron, yielding mainly  $\alpha\beta\gamma$ -tribromobutane, b. p. 102–103°/14 mm. The position of the bromine atoms is deduced from the observation that the compound reacts energetically with magnesium in the presence of ether, in accordance with the equations:  $2\text{C}_4\text{H}_9\text{Br}_2 + 3\text{Mg} = 3\text{MgBr}_2 + \text{C}_8\text{H}_{14}$  and  $\text{C}_4\text{H}_9\text{Br}_2 + 2\text{Mg} = \text{MgBr}_2 + \text{C}_4\text{H}_7\cdot\text{MgBr}$ . The former reaction predominates very greatly. If the product is treated with carbon dioxide, a hydrocarbon (or mixture of hydrocarbons),  $\text{C}_8\text{H}_{14}$ , and an acid,  $\text{C}_4\text{H}_7\cdot\text{CO}_2\text{H}$ , are obtained. The latter substance is present in too small quantity to permit its isolation, but its oxidation to methylmalonic acid shows it to have the constitution  $\text{CH}_3\cdot\text{CH}\cdot\text{CHMe}\cdot\text{CO}_2\text{H}$ . The hydrocarbon is oxidised to succinic acid, but does not appear to yield adipic acid. The course of the reaction differs entirely from that observed by von Braun and Deutsch (A., 1912, i, 106), and can only be explained simply on the assumption that the product is  $\alpha\beta\gamma$ -tribromobutane. Bromination of the  $\alpha\delta$ -compound, as in the case of  $\alpha\epsilon$ -dibromopentane (von Braun and Kirschbaum, A., 1920, i, 2), is accompanied by a displacement of a bromine atom. More vigorous bromination of  $\alpha\delta$ -dibromobutane leads to the production of  $\alpha\beta\gamma\delta$ -tetrabromobutane, m. p. 117°.

$\delta$ -Chlorobutylbenzamide, like the benzoyl derivative of  $\epsilon$ -chloro- $\alpha$ -methylamine, but unlike those of  $\gamma$ -chloropropylamine or  $\beta$ -chloroethylamine, reacts readily with aluminium chloride and benzene, yielding thereby *N*-benzoyl- $\delta$ -phenylbutylamine, m. p. 83° (cf. A., 1910, i, 819); the corresponding hydrochloride crystallises in leaflets, m. p. 159°.

*N*- $\delta$ -Chlorobutylbenzamide is transformed by diethylamine into

*N*-8-diethylaminobutylbenzamide,  $\text{NEt}_2(\text{CH}_2)_4\text{NHBz}$ , a colourless, viscous liquid, b. p.  $225\text{--}228^\circ/13\text{ mm.}$ , the salts of which exhibit little tendency to crystallise. It is hydrolysed by concentrated hydrochloric acid to 8-diethylaminobutylamine, a colourless, fairly mobile liquid, b. p.  $78\text{--}79^\circ/13\text{ mm.}$  (picrate, yellow needles, m. p.  $157^\circ$ ; chloroplatinate, yellow crystals, m. p.  $195^\circ$ ); it is remarkable that the base does not react with nitrous acid.

Sodium benzoisulphinide is converted by ethylene dibromide at  $170\text{--}180^\circ$  almost entirely into *N*-β-bromoethylbenzoisulphinide,  $\text{C}_6\text{H}_5\text{--}\langle\text{SO}_2\text{--CO}\rangle\text{N--CH}_2\text{--CH}_2\text{Br}$ . Under precisely similar conditions, trimethylene bromide gives α-*dibenzoisulphinidopropane*, a crystalline powder, m. p.  $196^\circ$ , in 47% yield. Tetramethylene bromide behaves similarly to the trimethylene compound, giving αδ-*dibenzoisulphinidobutane*,  $\text{C}_6\text{H}_5\text{--}\langle\text{SO}_2\text{--CO}\rangle\text{N--(CH}_2\text{)}_4\text{N--}\langle\text{SO}_2\text{--CO}\rangle\text{C}_6\text{H}_5$ , m. p.  $204\text{--}206^\circ$ , in 40% yield. H. W.

**Unsaturated Residues in Chemical and Pharmacological Relationship.** III. JULIUS VON BRAUN and GEORG LEMKE (*Ber.*, 1922, 55, [B], 3536--3559; cf. von Braun and Köhler, A., 1918, i, 162; von Braun and Braunsdorf, A., 1921, i, 772).—A further examination of the possibility of an intimate connexion between the peculiar physiological activity of compounds containing the allyl group, the relatively weak union of allyl with oxygen, nitrogen, sulphur, and halogen, and the β-γ-position of the double bond. The latter appears to be important in its effect on the physiological activity of the substances, since *N*-cinnamyl norcodeine is exactly analogous to *N*-allylnorcodeine in its antagonistic action towards morphine.

An extended study has been made of compounds containing the group  $\text{--CH}_2\text{--CH=CH--CH}_2\text{--}$ , since this may be regarded in a measure as a doubled allyl, and also because cases of *cis*- and *trans*-isomerism are to be expected. In the latter respect, the experiments are disappointing, since the initial material, *cis*-butadiene dibromide, is found to be unusually labile and to pass under the influence of a great variety of chemical reagents into the *trans*-modification of which it gives derivatives. The comparison of a series of compounds,  $\text{CH}_2\text{X--CH=CH--CH}_2\text{X}$ , with a similar series of substances,  $\text{CH}_2\text{X--CH}_2\text{--CH}_2\text{--CH}_2\text{X}$ , shows in general that the butadiene closely resemble the allyl derivatives in respect of the feeble union of the unsaturated carbon chain with halogen, oxygen, nitrogen, and sulphur. As is to be expected, the unsaturated compounds show less tendency to form the thiophene ring than does the saturated butane derivative, but, on the other hand, its ability to yield a pyrroline derivative (although only in small yield) is somewhat surprising.

When compared with the simpler allyl compounds, the butenyl compounds are unusually inactive physiologically, so that the chemical analogy of the substances is not accompanied by pharmacological analogy. This result appears to be due either to the

great increase in the size of the molecule or to the spatial proximity of the physiologically active centres in the presence of the chain  $\cdot\text{CH}_2\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}_2\cdot$ , which is such as to cause mutual disturbance.

*N*-Cinnamylnorcodeine,  $\text{OMe}\cdot\text{C}_{16}\text{H}_{14}\text{O}(\text{OH})\text{N}\cdot\text{CH}_2\cdot\text{CH}\cdot\text{CHPh}$ , a colourless substance, m. p.  $78^\circ$  after softening at  $74^\circ$ , is prepared by the treatment of a solution of norcodeine in chloroform with cinnamyl bromide at  $100^\circ$ ; the sulphate, hydrochloride, and chloroplatinate, a pale yellow powder, decomp.  $208^\circ$ , are described.

For the preparation of  $\alpha\delta$ -dibromo- $\Delta^2$ -butene,  $\alpha\beta\gamma\delta$ -tetrabromobutane is debrominated with zinc dust and alcohol, the  $\Delta^{\gamma\delta}$ -butadiene which is evolved is dissolved in chloroform and treated with one molecular proportion of bromine. The mixture of stereoisomerides thus produced is separated by rapid distillation under diminished pressure into the previously described solid *trans*- $\alpha\delta$ -dibromo- $\Delta^2$ -butene, b. p. about  $78\text{--}80^\circ/13$  mm., m. p.  $53^\circ$ , and *cis*- $\alpha\delta$ -dibromo- $\Delta^2$ -butene, b. p.  $59^\circ/13$  mm., which does not solidify in a freezing mixture of ice and salt. The constitution of the latter substance is now elucidated by the observation that it is oxidised by permanganate to a liquid glycol and finally to bromoacetic acid, but it appears doubtful whether the compound as thus prepared is quite homogeneous. It passes into the solid *trans*-modification slowly at the atmospheric temperature, rapidly when heated. The change is catalytically accelerated in particular by halogen acids, and to a smaller extent by sulphuric acid. The addition of hydrogen bromide to  $\alpha\delta$ -dibromo- $\Delta^2$ -butene is effected by protracted heating of the substance with a fuming solution of hydrogen bromide in glacial acetic acid at  $100^\circ$  (it is immaterial which modification of the dibromo-compound is used), whereby  $\alpha\beta\delta$ -tribromobutane, b. p.  $108\text{--}112^\circ/14$  mm., is produced in 65% yield (cf. von Braun and Deutsch, A., 1912, i, 106).  $\alpha\delta$ -Dibromo- $\Delta^2$ -butene is hydrolysed much more rapidly than  $\alpha\delta$ -dibromobutane by hot water. It is rapidly transformed by trimethylamine in the presence of benzene at  $20^\circ$  into the *diquaternary bromide*,

a very hygroscopic solid, m. p. about  $295\text{--}300^\circ$  (the corresponding chloroplatinate is a yellow powder, m. p.  $246^\circ$ ); under similar conditions of time, temperature, and concentration,  $\alpha\delta$ -dibromobutane remains unaffected, but when more drastically treated it becomes converted into the substance  $\text{NMe}_3\text{Br}\cdot[\text{CH}_2]_4\cdot\text{NMe}_3\text{Br}$ , m. p.  $295^\circ$ .  $\alpha\delta$ -Dibromobutane does not react with an ethereal solution of magnesium phenyl bromide, even on protracted heating; under similar conditions,  $\alpha\delta$ -dibromo- $\Delta^2$ -butene is fairly readily transformed into  $\gamma$ -benzylallyl bromide,  $\text{CH}_2\text{Ph}\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}_2\text{Br}$ , b. p.  $112\text{--}115^\circ/14$  mm. Treatment of  $\alpha\delta$ -dibromo- $\Delta^2$ -butene with a large proportion of the Grignard's reagent leads to the production of  $\alpha\delta$ -diphenyl- $\Delta^2$ -butene, which, however, could not be separated completely from diphenyl.

$\alpha\delta$ -Diphenoxy- $\Delta^2$ -butene,  $\text{OPh}\cdot\text{CH}_2\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}_2\cdot\text{OPh}$ , m. p.  $83\text{--}84^\circ$ , is readily prepared by boiling  $\alpha\delta$ -dibromo- $\Delta^2$ -butene with an alcoholic solution of sodium phenoxide. In striking contrast to  $\alpha\delta$ -diphenoxybutane, the unsaturated compound is extensively

decomposed at its boiling point, but it was not found possible to isolate the presumable product  $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}_2\cdot\text{C}_6\text{H}_4\cdot\text{OH}$  of the change or any of its derivatives in the homogeneous condition.

$\alpha\delta$ -Dibromo- $\Delta^2$ -butene reacts readily with ammonium thiocyanate dissolved in alcohol at  $0^\circ$  to give the *thiocyanate*,

prisms, m. p.  $82^\circ$ ; the constitution of the compound follows from the observations that it is indifferent towards bases, gives an intense odour of mercaptan when treated with zinc and hydrochloric acid, and is converted by thiobenzoic acid into the *dithiourethane*,  $\text{NH}_2\cdot\text{CS}\cdot\text{S}\cdot\text{CH}_2\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}_2\cdot\text{S}\cdot\text{CS}\cdot\text{NH}_2$ , m. p.  $165^\circ$  (decomp.). The thiocyanate is relatively very stable towards rise in temperature, differing in this respect from allyl thiocyanate; at  $150^\circ$ , however, it rapidly undergoes a complex change which does not lead to well-defined products. *Tetramethylene dithiocyanate*, b. p.  $193\text{--}195^\circ/14\text{ mm.}$ , is readily prepared in the usual manner; it is converted by thiobenzoic acid into tetramethylene bisdithiourethane, m. p.  $154^\circ$  (cf. von Braun, A., 1910, i, 13). For the preparation of tetramethylene dithiocarbimide,

a solution of tetramethylenediamine in alcohol is treated with carbon disulphide (whereby *tetramethylene dithiocarbamate*, m. p.  $150^\circ$ , is slowly precipitated) and subsequently with iodine, a solution of sodium in alcohol, and again with iodine; the *dithiocarbimide* is thus obtained as a yellow liquid which could not be caused to solidify. It is very unstable, and decomposes slowly when preserved at the atmospheric temperature, rapidly and completely when warmed. With aniline, it yields *NN'-diphenyltetramethylenedithiocarbimide*,  $\text{C}_6\text{H}_5(\text{NH}\cdot\text{CS}\cdot\text{NHPh})_2$ , m. p.  $169^\circ$ ; with an alcoholic solution of methylamine it gives *NN'-dimethyltetramethylenedithiocarbimide*, a crystalline powder, m. p.  $128^\circ$ , whilst with ammonia dissolved in alcohol it yields *tetramethylenedithiocarbimide*,  $\text{C}_4\text{H}_8(\text{NH}\cdot\text{CS}\cdot\text{NH}_2)_2$ , m. p.  $198^\circ$ .

The action of cyanogen bromide on an ethereal solution of  $\alpha\delta$ -tetramethyldiamino- $\Delta^2$ -butene leads to the production of *trans*- $\alpha\delta$ -dibromo- $\Delta^2$ -butene, dimethylcyanamide, and the quaternary compound,  $\text{NMe}_2\text{Br}\cdot\left\langle\begin{array}{c} \text{CH}_2\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}_2 \\ \text{CH}_3\cdot\text{CH}\cdot\text{CH}\cdot\text{CH}_3 \end{array}\right\rangle\text{NMe}_2\text{Br}$ , m. p.  $242^\circ$  (*chloroplatinate*, golden-yellow octahedra, m. p.  $294^\circ$ ). Since the possibility existed that the latter substance might in reality be *N*-dimethylpyrrolinium bromide,  $\left\langle\begin{array}{c} \text{CH}\cdot\text{CH}_2 \\ \text{CH}\cdot\text{CH}_2 \end{array}\right\rangle\text{NMe}_2\text{Br}$ , the latter was

prepared by the action of two molecular proportions of dimethylamine on a solution of  $\alpha\delta$ -dibromo- $\Delta^2$ -butene in benzene at  $100^\circ$ ; in contrast to the substance just described, it is a liquid which does not solidify even when strongly cooled (*chloroplatinate*, m. p.  $242^\circ$ ).  $\alpha\delta$ -Tetramethyldiaminobutane cannot be prepared directly from the corresponding bromide and dimethylamine, since the tendency towards ring formation is so great that *N*-dimethylpyrrolinium bromide is produced even when a large excess of the base is used. The ditertiary base, b. p.  $169^\circ$ , is, however, pre-

pared in very moderate yield by the decomposition of *NN'*-hexamethyltetramethylenediammonium hydroxide (cf. Willstätter and Heubner, A., 1907, i, 959); an unsaturated base, probably  $\delta$ -dimethylamino- $\Delta^8$ -butene,  $\text{NMe}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}:\text{CH}_2$ , b. p.  $82-85^\circ$ , is formed as by-product. The ditertiary base reacts energetically with cyanogen bromide, with elimination of methyl bromide from one or both ends of the molecule.

$\alpha\delta$ -Dibromobutane is converted quantitatively by aniline into 1-phenylpyrrolidine,  $\begin{smallmatrix} \text{CH}_2\cdot\text{CH}_2 \\ | \quad | \\ \text{CH}_2\cdot\text{CH}_2 \end{smallmatrix} > \text{NPh}$ , b. p.  $124^\circ/14$  mm., a colourless liquid which rapidly becomes brown when exposed to air; it gives a *picrate*, m. p.  $114^\circ$ , and a *methiodide*, m. p.  $150^\circ$ . Under precisely similar conditions,  $\alpha\delta$ -dibromo- $\Delta^8$ -butene gives minimal quantities of 1-phenyl- $\Delta^8$ -pyrroline,  $\begin{smallmatrix} \text{CH}\cdot\text{CH}_2 \\ | \quad | \\ \text{CH}\cdot\text{CH}_2 \end{smallmatrix} > \text{NPh}$ , a mixture of compounds formed by the action of several dibromide and aniline molecules and  $\alpha\delta$ -dianilino- $\Delta^8$ -butene,

$\text{NPh}\cdot\text{CH}_2\cdot\text{CH}:\text{CH}\cdot\text{CH}_2\cdot\text{NPh}$ ,  
a viscous liquid, b. p. above  $300^\circ/14$  mm., which is conveniently characterised as the *bis-nitrobenzoyl* derivative, slender needles, m. p.  $210^\circ$ .

When boiled with an aqueous alcoholic solution of potassium sulphide (under the conditions which lead to the production of tetrahydrothiophen from  $\alpha\delta$ -dibromobutane),  $\alpha\delta$ -dibromo- $\Delta^8$ -butene is converted into a complex, caoutchouc-like mass.

4-Pyrrolidinopantipyrene, m. p.  $128^\circ$ , is prepared by warming  $\alpha\delta$ -dibromobutane with 4-aminoantipyrene on the water-bath or from its components in alcoholic solution; the corresponding *hydrochloride* and *methiodide* could not be caused to crystallise. 4-Aminoantipyrene and  $\alpha\delta$ -dibromo- $\Delta^8$ -butene in the presence of acetone give complex products of high molecular weight and (in 40% yield), 4- $\Delta^8$ -pyrrolinoantipyrene, m. p.  $155^\circ$ .

$\gamma$ -Hydroxypropyldimethylamine reacts fairly readily with  $\alpha\delta$ -dibromobutane at  $100^\circ$  to yield *NN'*-tetramethyl-*NN'*-di- $\gamma$ -hydroxypropyltetramethylenediammonium bromide,

$\text{C}_4\text{H}_8(\text{NMe}_2\text{Br}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{OH})_2$ ,  
m. p.  $194^\circ$ , and with  $\alpha\delta$ -dibromo- $\Delta^8$ -butene in benzene solution to give *NN'*-tetramethyl-*NN'*-di- $\gamma$ -hydroxypropyl- $\Delta^8$ -butenylenediammonium bromide, a very hygroscopic solid, m. p.  $188^\circ$  (*chloroplatinate*, m. p.  $213^\circ$ ).

$\alpha\delta$ -Dibromo- $\Delta^8$ -butene is converted by an excess of norcodeine dissolved in chloroform into  $\alpha\delta$ -dinorcodeyl- $\Delta^8$ -butene,

$\text{C}_4\text{H}_6[\text{N}:\text{C}_{16}\text{H}_{14}\text{O}(\text{OH})\cdot\text{OMe}]_2$ ,  
m. p.  $132^\circ$  after softening at  $125^\circ$ ; the corresponding *sulphate*, *hydrochloride*, *chloroplatinate*, and *picrate* are described.  $\alpha\delta$ -Dibromobutane and norcodeine, on the other hand, give exclusively *norcodeiniumpyrrolidinium bromide*,  $\text{C}_4\text{NH}_8\text{Br}\cdot\text{C}_{16}\text{H}_{14}\text{O}(\text{OH})\cdot\text{OMe}$ .

$\alpha\delta$ -Dibromobutane, hydrocyprine, and alcoholic potassium hydroxide solution give  $\alpha\delta$ -dihydrocyprylbutane,  $\gamma$  decomp.  $232^\circ$ , in 56% yield. In similar circumstances,  $\alpha\delta$ -dibromo- $\Delta^8$ -butene

yields  $\alpha\delta$ -dihydrocupreyl- $\Delta^8$ -butene, m. p. 215—218° after becoming black at 200°. H. W.

**A Synthesis of  $\beta$ -Chloroallyl Chloride.** ARTHUR J. HILL and EDWIN J. FISCHER (*J. Amer. Chem. Soc.*, 1922, 44, 2582—2595).—Starting from glycerol,  $\beta$ -chloroallyl chloride may be prepared with good yields by the following procedure. The glycerol, previously dehydrated, is saturated with dry hydrogen chloride after the addition of glacial acetic acid to the extent of 6% of its weight as a catalyst. The  $\alpha\gamma$ -dichlorohydrin mixed with a small amount of the  $\alpha\beta$ -isomeride is converted into epichlorohydrin by pouring it into 30% aqueous sodium hydroxide at 12—15°. The epichlorohydrin is then reconverted into the  $\alpha\gamma$ -dichlorohydrin by the action of concentrated hydrochloric acid. To 300 g. of the dichlorohydrin are added 240 g. of phosphoryl chloride and the mixture is heated on a water-bath for three hours and then for five hours at 180°, after which it is distilled under slightly diminished pressure. Between 225° and 230°,  $\beta$ -chloroallyl chloride distils over. Phosphoric oxide may be used instead of the oxychloride, but the yield is thereby considerably reduced. In either case, the dehydration of the dichlorohydrin is preceded by ester formation, and the higher temperature is necessary for the decomposition of these intermediate products. Other dehydrating agents tried were potassium hydrogen sulphate, sulphuric acid, oxalic acid, boric anhydride, thionyl chloride, and phosphorus trichloride, but in no case could the chloroallyl chloride be obtained.

$\beta$ -Chloroallyl chloride may be used for the alkylation of malonic esters, and the following compounds have been prepared. *Diethyl chloroallylmalonate*, b. p. 161—163°/12 mm., *diethyl di(chloroallyl)malonate*, b. p. 190°/12 mm. or 300°/760 (decomp.), and *diethyl ethylchloroallylmalonate*, b. p. 157—160°/12 mm. W. G.

**Purification of Methyl Alcohol by means of Sodium Hypochlorite.** ROBERT CHARLES MENZIES (*T.*, 1922, 121, 2787—2793).

**Union of Hydrogen with Acetylene Derivatives. XIII. Mechanism of the Catalytic Hydrogenation of Dimethylhexinenediol.** J. S. ZALKIND and (Mlle) M. S. PESCHEROKOVA (*J. Russ. Phys. Chem. Soc.*, 1920, 52, 186—190).—The values obtained by Zalkind and Pischtschikov (*A.*, 1915, ii, 435) for the velocity of hydrogenation of tetramethylbutinenediol in presence of colloidal palladium showed that, as the reaction proceeds, the value of  $k$ , calculated from the formula for unimolecular reactions, at first increases. Such increase was regarded as due to the gradual removal of the acetylenic glycol. Further experiments show that this is not the case. The velocity of the reaction is found to be greatly increased if the palladium is first saturated with hydrogen and then left for some time (sixty hours) in contact with the acetylenic glycol prior to commencement of the hydrogenation. The retardation of the hydrogenation in its early stages is evidently due to the formation, either chemically or by adsorption, of intermediate compounds. "H. P.

**Equilibrium in Systems Composed of Water and Alcohols : Methyl Alcohol, Pinacone, Glycerol, and Erythritol.** NICOLAI ANTONOVICH PUSHIN and ALEXANDRA ALEXANDROVNA GLAGOLEVA (T., 1922, 121, 2813—2822).

**Catalytic Dehydration of Alcohols in the Wet Way. I. Olefines and Cyclenes.** J. B. SENDERENS (*Ann. Chim.*, 1922, [ix], 18, 117—145; cf. A., 1912, i, 406).—A review of the author's work on this subject (A., 1910, i, 649, 651; 1912, i, 331, 441), from which the conclusion is drawn that, of the available catalysts, aluminium sulphate and potassium hydrogen sulphate are of restricted application whilst concentrated sulphuric acid is effective in almost all cases. Theoretically, the dry method of catalysis is more efficient, but in practice the wet method is preferable, owing to its rapidity and the ease with which it may be carried out. H. J. E.

**Catalytic Dehydration of Alcohols in the Wet Way. II. Ester-formation.** J. B. SENDERENS and J. ABOULENO (*Ann. Chim.*, 1922, [ix], 18, 145—188; cf. preceding abstract, *Ann. Berthelot*, A., 1879, 866, and Fischer and Speier, A., 1896, i, 201).—A general review of the authors' work (A., 1911, i, 600, 637; 1912, i, 694; 1913, i, 41, 42; 1914, i, 379) shows that concentrated sulphuric acid is by far the most advantageous catalyst, operating efficiently in all the different variations of the general reaction. H. J. E.

**Vapour Pressures, Densities, and some Derived Quantities for Ethyl Ether at Low Temperatures.** ROBERT S. TAYLOR and LEIGHTON B. SMITH (*J. Amer. Chem. Soc.*, 1922, 44, 2450—2463).—The densities and vapour pressures of ethyl ether have been measured over the lower range of temperature. The following density values are recorded:  $-120^{\circ}$ , 0.86195;  $-110^{\circ}$ , 0.85192;  $-80^{\circ}$ , 0.82141;  $-75^{\circ}$ , 0.81640;  $-70^{\circ}$ , 0.81114;  $-50^{\circ}$ , 0.79032;  $-45^{\circ}$ , 0.78510;  $-40^{\circ}$ , 0.77970;  $-35^{\circ}$ , 0.77425;  $0^{\circ}$ , 0.73629;  $20^{\circ}$ , 0.71349;  $35^{\circ}$ , 0.69576;  $40^{\circ}$ , 0.68979;  $55^{\circ}$ , 0.67116, and  $60^{\circ}$ , 0.66501. It is found that the density above  $0^{\circ}$  is represented by the equation  $d=73629-0.001138t-0.000001237t^2$ , and that below  $0^{\circ}$  by  $d=0.73629+0.0011044t-0.0000004772t^2$ . From these equations, the density and specific volume have been calculated for every  $5^{\circ}$  from  $-120^{\circ}$  to  $+70^{\circ}$  and the values compared with the present results and those of other investigators. The recorded vapour pressure values are:  $-60.799^{\circ}$ , 3.95 mm.;  $-55.748^{\circ}$ , 5.93 mm.;  $-50.873^{\circ}$ , 8.77 mm.;  $-45.998^{\circ}$ , 12.62 mm.;  $-41.125^{\circ}$ , 17.78 mm.;  $-36.231^{\circ}$ , 24.77 mm.;  $-31.329^{\circ}$ , 34.03 mm.;  $-26.421^{\circ}$ , 45.81 mm.;  $-21.502^{\circ}$ , 61.31 mm.;  $-16.578^{\circ}$ , 80.67 mm.;  $-11.637^{\circ}$ , 104.79 mm.;  $-6.698^{\circ}$ , 134.76 mm.;  $+0.009^{\circ}$ , 186.13 mm.;  $+4.975^{\circ}$ , 233.73 mm.;  $+9.937^{\circ}$ , 290.62 mm.;  $+14.903^{\circ}$ , 358.15 mm.;  $+19.871^{\circ}$ , 437.70 mm. It is found that the vapour pressures between  $-60^{\circ}$  and  $+20^{\circ}$  are given by the equation  $\log p = -(2168.599/T) + 13.882702 - 0.01814165T + 0.000017181957T^2$ , and by means of this formula the values of the vapour pressure have been calculated for every five degrees over the range  $-65^{\circ}$

to  $+25^{\circ}$  and the values compared with the present experimental values. From the above-mentioned data and an equation of condition, the latent heats of evaporation and the change in internal energy on evaporation have been calculated. A relationship connecting the specific volume of the liquid and the internal energy change on evaporation is given. From the latent heats there was obtained the difference in saturation specific heats of the vapour and liquid, and from these, when compared with Regnault's values for the liquid, some values of the specific heat of the vapour at constant pressure were deduced. J. F. S.

**The Oxidation of  $\alpha\delta$ - and  $\alpha\epsilon$ -Oxides.** ADOLF FRANKE and FRITZ LIEBEN (*Monatsh.*, 1922, 43, 225—236).—The oxidation with potassium permanganate of a number of anhydrides of  $\alpha\delta$ - and  $\alpha\epsilon$ -glycols was studied to determine whether it would be possible to deduce the constitution of such compounds from their oxidation products.  $\alpha\epsilon$ -Oxidopentane was converted smoothly into glutaric acid whilst  $\alpha\epsilon$ -oxidoheptane gave principally succinic and acetic acids, rupture of the ring taking place between the  $\delta$  and  $\epsilon$  carbon atoms. The latter oxidation therefore follows the same lines as that of  $\alpha\delta$ -oxidopentane, which gave principally acetic and oxalic acids (not the expected malonic acid), and only to a small extent formic and succinic acids. It is noteworthy that the  $\alpha\epsilon$ -oxidoheptane prepared from 1:5-hexandiol was identical with that previously prepared from 1:6-hexandiol (*Monatsh.*, 1914, 35, 931). This follows, not only from their similar physical properties, but also from their identical oxidation products. When the oxide contains a tertiary carbon atom, oxidation goes only as far as the lactone; thus  $\beta\gamma$ -oxido- $\beta$ -methylhexane gives  $\delta$ -methylhexolactone,  $\text{OMe}(\text{CH}_2)_3\text{CO}$ , and only very little acetone and succinic acid.

E. H. R.

**Trichloroethyl Carbamate.** R. WILLSTÄTTER, W. DUISBERG, and T. CALLSEN (U.S. Pat. 1427506).—*Trichloroethyl carbamate*, white needles, m. p.  $64$ — $65^{\circ}$ , is obtained by interaction of carbamyl chloride and trichloroethyl alcohol in ethyl ether solution.

CHEMICAL ABSTRACTS.

**Researches on Residual Affinity and Co-ordination. XIV. Interactions of Metallic Salts and Dimethyldithiolethylene.** GILBERT T. MORGAN and WILFRID LEDBURY (*T.*, 1922, 121, 2882—2894).

**Synthesis of Alkylidenecyanoacetic Acids and of Substituted Succinic Acids. II. Preparation of Acids containing Saturated Aliphatic Residues and the Constitution of the Aliphatic Alkylidenecyanoacetic Esters.** ARTHUR LAPWORTH and JOHN ALEXANDER McRAE (*T.*, 1922, 121, 2741—2755).

**Catalytic Hydrogenation and the Potential of the Hydrogen Electrode.** JAMES B. CONANT and HAROLD B. CUTTER (*J. Amer. Chem. Soc.*, 1922, 44, 2651—2654).— $\beta\beta$ -Dimethylacrylic acid

can be hydrogenated in 0.1N-hydrochloric acid solution by hydrogen in the presence of a catalyst, but is not reduced by chromous chloride in aqueous solution, although the reducing power of the latter reagent, as measured by its oxidation-reduction potential, is 0.3 volt greater than that of the former reagent. Maleic acid is reduced by chromous chloride, but not by sodium hyposulphite, whilst dibenzoyl ethylene is reduced by both reagents. As a result of these tests, the authors consider that the process of catalytic hydrogenation cannot be successfully formulated in terms of oxidation-reduction potentials. It is suggested that in one case there is a process of hydrogenation, that is, the simple adding on of hydrogen atoms, whilst in the other case there is reduction, that is, the process involves electron addition and is of an irreversible type.

W. G.

**Unsaturated Fatty Acids of Brain Cephalins.** P. A. LEVENE and IDA P. ROLF (*J. Biol. Chem.*, 1922, **54**, 91—98).—An investigation of the fatty acids of brain cephalin on the lines recently applied to lecithin (cf. A., 1922, i, 621) has shown that stearic, oleic, and arachidonic acids are present in cephalin. Other saturated and unsaturated acids are also present, but have not yet been isolated in a pure state. No evidence has been obtained of the presence of linolic acid.

E. S.

**Unsaturated Fatty Acids of Brain Lecithins.** P. A. LEVENE and IDA P. ROLF (*J. Biol. Chem.*, 1922, **54**, 99—100).—The fatty acids from brain lecithin contain oleic and arachidonic acids.

E. S.

**Preparation and Properties of Tri-iodopyruvic Acid.** M. GARINO and E. ZUNINI (*Gazzetta*, 1922, **52**, ii, 220—225).—Tri-iodopyruvic acid,  $C_3H_3O_4I_3$ , prepared by treating pyruvic acid with iodic and hydriodic acids, forms lemon-yellow crystals with a slightly pungent odour, m. p. about 97°. It is highly unstable, especially in contact with organic substances and under the influence of light; its aqueous solution is relatively stable if iodic acid is present.

T. H. P.

**Glucinum Compounds.** JULIUS MEYER and ERWIN MANTEL (*Z. anorg. Chem.*, 1922, **123**, 43—55).—Glucinum salts of organic acids are very difficult to obtain in the pure crystalline form; the composition, properties, and constitution of many of these salts have not been clearly proved. The authors attempted to prepare the malonate, but were unable to obtain the pure product. They were, however, able to prepare some double salts, to which they assign the constitution  $[Gl(CH_2(CO_2)_2)_2]K_2$ ,  $[Gl(CH_2(CO_2)_2)_2]Na_2 \cdot H_2O$ , and  $[Gl(CH_2(CO_2)_2)_2](NH_4)_2$  (cf. Wirth, A., 1914, i, 657). The authors discuss the constitution of basic glucinum acetate and they argue that Glasmann's structure (cf. A., 1908, i, 120) cannot be accepted. Biltz's suggestion,  $[Gl(\overset{HO}{\underset{HO}{|}}|)_3]OAc$ , is also shown to be untenable. The present authors suggest  $[GlO(Gl(OAc)_2)_3]$ . They were, however, unable to find much support for this structure.

W. T.

b\* 2

**Tervalent Manganese. III.** JULIUS MEYER and WALTER SCHRAMM (*Z. anorg. Chem.*, 1922, 123, 56—68).—Diaquo-dimalonatomanganic acid was prepared,  $[\text{Mn}(\text{H}_2\text{O})_2(\text{CH}_2(\text{CO}_2)_2)_2]\text{H}$ , as well as its lithium, sodium, potassium, rubidium, and ammonium salts. These compounds are olive-green, they dissolve in water, forming yellow solutions, and they are readily hydrolysed with the separation of manganic hydroxide. The potassium salt of trimalonatomanganic acid,  $[\text{Mn}(\text{CH}_2(\text{CO}_2)_2)_3]\text{K}_3$ , was prepared from the above potassium salt. This substance is red, but from a concentrated solution, especially in the presence of malonic acid, green crystals of the potassium diaquo-dimalonatomanganate separate. The tri-lithium, -sodium, and -ammonium salts could not be obtained in a pure state owing to their very high solubility. The tripotassium salt was found to be stable towards light (cf. the analogous oxalate). The colour and constitution of manganic salts are briefly discussed. W. T.

**Formation of  $\gamma$ -Alkylidene Derivatives from Ethylidene-malonic Ester.** LUCY HIGGINBOTHAM and ARTHUR LAPWORTH (*T.*, 1922, 121, 2823—2830).

**The Conditions Underlying the Formation of Unsaturated and Cyclic Compounds from Halogenated Open-chain Derivatives. V. Products Derived from  $\alpha$ -Halogenated  $\beta$ -Methylglutaric Acids.** CHRISTOPHER KELK INGOLD (*T.*, 1922, 121, 2676—2695).

**The Neutralisation of Tartaric Acid in Presence of Metallic Chlorides. Neutral and Buffer Zones.** L. J. SIMON (*Compt. rend.*, 1922, 175, 887—890; cf. Simon and Zivy, *A.*, 1922, ii, 880).—A mixture of potassium tartrate and potassium hydrogen tartrate constitutes a buffer solution, and the author has studied the effect of adding to it copper, zinc, and ferric chlorides. In the case of copper, the buffer effect increases and the results obtained point to the existence of a cupropotassium complex,

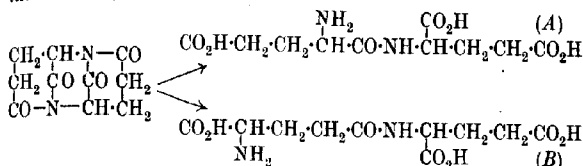

(cf. Masson and Steele, *T.*, 1899, 75, 725). Although a complex,  $\text{C}_4\text{H}_4\text{O}_6\text{KZn}\cdot\text{OH}$ , may be formed on addition of zinc chloride, the buffer effect is unaltered, but the presence of ferric chloride leads to a marked decrease of the zone in which the effect is obtained.

H. J. E.

**The Action of Glycerol on Glutamic Acid when Heated. Formation of *cyclo*Glutamylglutamic Acid (2:5-Diketopiperazine-3:6-dipropionic Acid) and of Glutamylglutamic Acid.** A. BLANCHETIÈRE (*Bull. Soc. chim.*, 1922, [iv], 31, 1045—1063).—The condensation of glutamic acid in presence of glycerol (cf. Abderhalden and Kautzsch, *A.*, 1910, i, 230, 768) was effected on heating at 170° for eight hours, yielding a product which was separated as barium salt by addition of baryta water. The product is not a polyglutamic acid analogous to the polyaspartic acids (cf. Schaal, *A.*, 1871, 129; also Schiff, *A.*, 1898, i, 67; 1899, i, 195), but 2:5-diketopiperazine-3:6-dipropionic acid. By treat-

ment with aqueous sodium hydroxide, the substance was converted into glutamic acid, passing through the intermediate stage of glutamylglutamic acid. The latter was separated by Fischer's original method, and on evaporation from alcohol-water mixture yielded an amorphous mass, m. p. 167—168°. From a consideration of the constitution of the *cyclo*-acid, it is probable that cleavage of the molecule may occur in two ways (cf. Ravenna, A., 1922, i, 180) and that the acid thus obtained is a mixture of the two possible products. The reaction is shown structurally as follows, the formula A representing the substance which forms the bulk of the mixture :

H. J. E.

**The Preparation of Ethanetetracarboxylic Acid.** C. MANNICH and ERICH GANZ (*Ber.*, 1922, 55, [B], 3509—3510).—The preparation of ethanetetracarboxylic acid in moderate amount by the hydrolysis of the corresponding ester is greatly hampered by the difficulty of effecting the reaction by acid or alkali in a satisfactory manner (cf. Philippi and Hanusch, A., 1920, i, 594). It is therefore preferable to obtain the acid by the catalytic hydrogenation of ethylenetetracarboxylic acid dissolved in acetone in the presence of palladised charcoal. The elimination of carbon dioxide during the process cannot be completely avoided, but the pure acid, m. p. 167—169° (decomp.), can be isolated by repeated crystallisation of the crude product from acetone. H. W.

**The Action of Hydrogen Peroxide on Formaldehyde.**  
**The Theory of Oxidative Processes.** A. BACH and A. GENEROSOW (*Ber.*, 1922, 55, [B], 3560—3566).—Formaldehyde is oxidised by hydrogen peroxide to formic acid and hydrogen. The latter must be derived either from the water or the hydrogen peroxide, and since it is also obtained by the use of other hydrogen-free oxidising agents (potassium chromate, potassium permanganate, lead oxide) in alkaline solution, it appears valid to assume that it originates from the water. The hydrogen peroxide appears to be protected from reduction by the liberated hydrogen by the formation of a complex compound with formaldehyde, the reduction of which is a slower process than the union of the hydrogen atoms to molecules. The interpretation of the course of the reaction in accordance with Traube's theory of oxidation in the presence of water assumes that the formaldehyde molecule in consequence of the removal of a hydrogen atom by oxidation acquires the power of combining with a hydroxyl-ion with the production of formic acid and liberation of the equivalent quantity of hydrogen, whereas

Wieland's theory requires that the formaldehyde hydrate molecule should be able by partial dehydrogenation to decompose spontaneously into formic acid and hydrogen, thus:  $\text{CH}_2\text{O} + \text{H}_2\text{O} = \text{CH}_2(\text{OH})_2$ .  $2\text{CH}_2(\text{OH})_2 + \text{H}_2\text{O}_2 = 2\text{CH}(\text{OH})_2 + 2\text{H}_2\text{O}$ .  $2\text{CH}(\text{OH})_2 = 2\text{CH}_2\text{O} + \text{H}_2$ . The observed facts are best interpreted by the former theory.

Wieland's application of the dihydrogenation theory to biological oxidative processes is criticised at length. The experimental foundation of Wieland's assumption of the identity of oxidising and reducing ferments rests on observations with tissues and their extracts, which are unsuitable for the purpose, since they show not only oxidising and reducing but also hydrolytic properties. In spite of many attempts, it has not been found possible to effect a reduction with purified peroxydase.

H. W.

**Preparation of  $\alpha$ -Trioxymethylene and a New Polymeride of Formaldehyde.** DALZIEL LLEWELLYN HAMMICK and ALFORD REGINALD BOEREE (T., 1922, 121, 2738—2740).

**Preparation of Acetaldehyde.** E. WERTHEIM (*J. Amer. Chem. Soc.*, 1922, 44, 2658—2659).—Certain modifications are suggested in the method of Adams and Williams (cf. A., 1922, i, 222) for the preparation of acetaldehyde by the oxidation of alcohol. The mechanical stirring is replaced by a steady stream of carbon dioxide. The oxidising agent recommended is a mixture of 115 g. of nitric acid (*d* 1.42), 60 g. of sodium dichromate, 20 g. of sulphuric acid (*d* 1.84), and 220 c.c. of water, these quantities sufficing to oxidise 25 g. of alcohol. The alcohol is heated to boiling and the oxidising mixture is run slowly into it, the time taken being about twenty minutes.

W. G.

**A New Extractive and Absorptive Medium for Scientific and Technical Purposes.** GERHARD SCHMITT (*Petroleum Times*, 1922, 8, 249—250).—A solution of sulphur dioxide in acetone (equal parts) has great solvent power for unsaturated organic compounds and resinous substances, and possesses all the advantages of liquid sulphur dioxide whilst it is more convenient to manipulate. It is easily recovered by distillation, there being practically no chemical action on the extracted substance; moreover, extraction can be carried out at low temperatures in an open vessel. Its application to the extraction of soluble substances from coal, lignite, etc., is specially mentioned.

CHEMICAL ABSTRACTS.

**Ethoxymethylenediacyl** [ $\alpha$ -Ethoxy- $\Delta^5$ -pentene- $\gamma$ -dione] and  $\alpha$ -Ethoxyethylane- $\gamma$ -dione. OTTO DIELS and JUSTUS PETERSEN (*Ber.*, 1922, 55, [B], 3449—3457).—The only representative of the simple  $\alpha\beta$ -unsaturated 1:2-diketones which has been described previously is styryl methyl diketone,  $\text{CHPh}:\text{CH}\cdot\text{CO}\cdot\text{CO}\cdot\text{Me}$  (Diels and Andersonn, A., 1911, i, 464; Diels and Sharkoff, A., 1913, i, 875). A second member of this class, ethoxymethylenediacyl, has now been prepared and examined.

*Ethoxymethylenediacetyl* [ $\alpha$ -ethoxy- $\Delta^5$ -pentene- $\gamma\delta$ -dione],

is prepared in poor yield by the action of ethyl orthoformate on dimethyl diketone dissolved in boiling acetic anhydride: 'It is a dark yellow liquid, b. p.  $85-86^\circ/10$  mm.,  $d_4^{15}$  1.0532,  $n_D^{15}$  1.44950,  $n_D^{17}$  1.46601, which solidifies completely at  $-20^\circ$  to a mass of yellow crystals which melts at  $-10^\circ$ . Its vapours have a pronounced olive-green colour. It somewhat readily becomes viscous, and ultimately resinifies when preserved. It is rapidly decomposed by alkali hydroxides, ammonia, and concentrated acids, but the sensitiveness of the substance to these reagents is such that definite products of the change cannot be isolated. When treated with *o*-phenylenediamine in the presence of pyridine, it gives the *quinazoline* deriv-

ative,  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{N}=\text{CMe} \\ \text{N}=\text{C}\cdot\text{CH}:\text{CH}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2 \end{smallmatrix}$ , leaflets, m. p.  $183^\circ$ .

With aniline in methyl-alcoholic solution, it gives the *anilaniide*, small, colourless needles, m. p.  $187-188^\circ$ , to which the constitution  $\text{NPh}\cdot\text{CH}:\text{CH}\cdot\text{CO}\cdot\text{CMe}\cdot\text{NPh}$  is ascribed. When treated with phenylhydrazine under very mild conditions, the ethoxymethylene compound yields the *monophenylhydrazone*,  $\text{OEtCH}:\text{CH}\cdot\text{CO}\cdot\text{CMe}\cdot\text{N}\cdot\text{NHPh}$ , yellowish-brown rodlets, m. p.  $152^\circ$ , the constitution of which is established by the observation that, under more energetic conditions, a second molecular proportion of phenylhydrazine enters into the reaction, whereby the *pyrazole* derivative,

pale yellow leaflets, m. p.  $182^\circ$ , is formed. The addition of piperidine to a solution of ethoxymethylenediacetyl in light petroleum leads to the formation of the *piperidide*,  $\text{C}_{10}\text{H}_{15}\text{O}_2\text{N}$ , lemon-yellow needles, m. p.  $81.5^\circ$ .

Ozonisation of  $\alpha$ -ethoxy- $\Delta^5$ -butene- $\gamma\delta$ -dione dissolved in chloroform and subsequent decomposition of the oily *ozonide* with water leads to the production of  $\alpha\beta$ -diketobutaldehyde,  $\text{CH}_3\cdot\text{CO}\cdot\text{CO}\cdot\text{CHO}$ ; the compound has not yet been isolated, but its existence is placed beyond doubt by the conversion of the crude material by means of *o*-phenylenediamine into the *quinazoline* derivative,

leaflets, m. p.  $166^\circ$ .

$\alpha$ -Ethoxy- $\Delta^5$ -pentene- $\gamma\delta$ -dione is smoothly hydrogenated in methyl-alcoholic solution in the presence of colloidal palladium to  $\alpha$ -ethoxypentane- $\gamma\delta$ -dione,  $\text{OEt}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CO}\cdot\text{CMe}$ , b. p.  $70-73^\circ/13$  mm.,  $d_4^{15}$  1.0690,  $n_D^{15}$  1.43588,  $n_D^{17}$  1.44477, which is much more stable than the corresponding unsaturated compound; the *disemicarbazone*, m. p.  $244^\circ$  (decomp.) after previous darkening, is described.

Attempts have been made to replace dimethyl diketone in the condensation just described by the less expensive methyl ether of its oxime,  $\text{CH}_3\cdot\text{CO}\cdot\text{CMe}\cdot\text{N}\cdot\text{OMe}$ . In this case, however, the use of ethyl orthoformate and acetic anhydride is unsuccessful. The

alternative method of condensation (action of sodium ethoxide and ethyl orthoformate) gives well-defined products in the formation of which the ester does not take a part. The isolation of a substance,  $\text{OMe}\cdot\text{N}\cdot\text{CMe}\cdot\text{CO}\cdot\text{CH}\cdot\text{CMe}\cdot\text{CMe}\cdot\text{N}\cdot\text{OMe}$ , long, lustrous needles, m. p.  $50^\circ$  (phenylhydrazone,  $\text{C}_{16}\text{H}_{23}\text{O}_2\text{N}_4$ , yellow leaflets, m. p.  $110^\circ$ ), and of a product,  $\text{C}_{10}\text{H}_{16}\text{O}_3\text{N}_2$ , hexagonal leaflets, m. p.  $138.5^\circ$ , is described; the constitution of the latter has not been elucidated. H. W.

**1:3:4:6-Tetramethyl Fructose.** JAMES COLQUHOUN IRVINE and JOCELYN PATTERSON (T., 1922, 121, 2696—2703).

**Structure of Fucose.** E. P. CLARK (J. Biol. Chem., 1922, 54, 65—73).—The method for the preparation of fucose has been improved. Using the methods employed by Hudson and Chernoff (A., 1918, i, 335) in the case of rhamnose, a methyl tetronolactone, m. p.  $110^\circ$ ,  $[\alpha]_D^{20} -63.65^\circ$ , and a methyl tetronamide, m. p.  $112.5^\circ$ ,  $[\alpha]_D^{20} +18.48^\circ$ , have been obtained from fucose. Fuconic acid, when saturated with ammonia in alcoholic solution, yields fuconamide, m. p.  $180.5^\circ$ ,  $[\alpha]_D^{20} -31.13^\circ$ . On the basis of the relationships which exist between the configuration and rotation of lactones and amides of sugar acids (Hudson, A., 1910, i, 220; 1918, i, 293), it is concluded from the above data that the configuration assigned to fucose by Mayer and Tollens (A., 1907, i, 588) is correct. E. S.

**Oxidation of Carbohydrates with Nitric Acid.** PAUL HAAS and BARBARA RUSSELL-WELLS (Biochem. J., 1922, 16, 572—573).—The carbohydrate constituents of *Chondrus crispus*, sucrose, lactose, dextrose, and laevulose, on oxidation with nitric acid, yield a substance similar to glycuronic acid which reduces Fehling's solution in the cold. Attempts to prepare a crystalline oxime, phenylhydrazone, *p*-bromophenylhydrazone, or a cinchonine salt failed. S. S. Z.

**The Oxidation of Sucrose by Nitric Acid.** FREDERICK DANIEL CHATTAWAY and HINTON JOHN HARRIS (T., 1922, 121, 2703—2709).

**Cellulose. III. Determination of the Viscosity of Cellulose.** MICHIMARO NAKANO (J. Chem. Ind. Japan, 1922, 25, 899—910).—The author has studied the preparation of the cuprammonium solution and the effects of various factors on the viscosity of the cuprammonium solution of cellulose, the result being summarised as follows. The viscosity decreases with time until it attains a constant value. A dilute solution attains a constant value more rapidly than a concentrated one, but with a very dilute solution the value is constant from the beginning. With solutions of the same concentration, the lower the viscosity the less is the difference between the final and initial values; the viscosity increases much more rapidly than the concentration. The relative viscosity increases with the temperature. No appreciable decrease of viscosity due to a small loss of ammonia could be observed. Oxygen and light have the largest effect on the viscosity. The depolymerisation of the molecular aggregate of cellulose is due to the

action of light. Of the various preliminary treatments of cellulose, the thermal treatment is the deciding factor for viscosity. K. K.

**Nature of the Swelling Process. VI. Swelling and Partition of Cellulose Acetate in Organic Solvents.** F. KNOEVENAGEL, J. HOGREFE, and F. MERTENS (*Koll. Chem. Beihefte*, 1922, **16**, 180—214; cf. A., 1921, i, 402, 709, 710, 771).—The swelling and partition of cellulose acetate in the mixtures, acetic acid-water, acetic acid-benzene, acetone-benzene, nitrobenzene-*iso*-propyl alcohol, ethyl alcohol-benzene, nitrobenzene-benzene, ethyl alcohol-water, acetic acid-nitrobenzene, acetone-nitrobenzene, methyl alcohol-nitrobenzene, acetone-methyl alcohol, and acetic acid-camphor has been investigated. Cellulose acetate soluble in acetone or chloroform or insoluble in acetic acid was used in the various experiments. The present experiments are an extension of those previously published (*loc. cit.*), and show that alcohols, benzene, and water in varying quantities are taken up by cellulose acetate in constant amounts. In these cases, the law of constant combining proportions is applicable, and it is suggested that where this law holds it is well to speak of compounds and to regard the taking up of the liquids as a chemical process. The compounds involved in these cases are in all probability of a higher order than molecular compounds. The valency involved in these cases is shown to be due to electrical forces. The nature of this type of combination is considered, and it is shown that the swelling process consists of a reaction between two molecules and is of a chemical nature. J. F. S.

**Hydrocellulose.** EMIL HEUSER and WALTER VON NEUENSTEIN (*Cellulosechemie*, 1922, **3**, 89—96).—According to recent theories (Herzog and Jancke, A., 1921, ii, 532; Karrer, A., 1922, i, 231), the cellulose substance is built up of double molecules of anhydrocellobiose, which are systematically arranged in crystal symmetry and held together by special affinities called crystal valencies. These crystal valencies are assumed to be released by all processes which destroy the fibrous structure. The attack on the crystal valencies produces only physical changes, converting the fibrous crystal cellulose into amorphous cellulose, the double anhydrocellobiose molecules remaining intact. The first stage of chemical hydrolysis would involve an attack on the anhydride position of one of the cellobiose residues, without depolymerising the unit, and it is suggested that hydrocellulose is thus formed, consisting of cellobiose-anhydrocellobiose differing from the simple amorphous cellulose as regards the open carbonyl group, but not in molecular dimensions. Further hydrolysis involves the first stage of depolymerisation with formation of free cellobiose, accompanied or closely followed by the second stage, with formation of dextrose. Girard's hydrocellulose produced from fibrous cellulose is a mixture of cellulose and true hydrocellulose, but the hydrocellulose produced by Knoevenagel and Busch's method (A., 1922, i, 636) from viscose cellulose is a homogeneous hydrocellulose, because it is formed from cellulose in which the crystal valencies

have already been resolved. This view is supported by the preparation of highly methylated derivatives by Denham and Woodhouse's method. Ordinary cotton cellulose, on repeated methylation, gave a product corresponding with dimethylcellulose, almost completely insoluble in cold water and in organic solvents. The product from the pure hydrocellulose of Knoevenagel and Busch, with the same methoxyl content, was completely soluble in these media and behaved as a uniform substance. Girard's hydrocellulose yielded a mixed product, partly soluble like that from the pure hydrocellulose and partly insoluble like that from ordinary cotton. In no case was a trimethylated derivative obtained. The dimethylhydrocellulose from Knoevenagel and Busch's product yielded on acetylation principally monoacetyldimethylhydrocellulose soluble in organic solvents and with relatively low melting point. Determinations of molecular weights of these derivatives gave low but inconclusive results.

J. F. B.

**Plant Colloids. XIV. Physico-chemical Analysis of Agar Jellies.** M. SAMEC and V. ISAJEVIĆ (*Koll. Chem. Beihefte*, 1922, **46**, 285—300; cf. A., 1922, i, 921).—Agar-agar is shown to contain a not inconsiderable quantity of electrolytes, which are so closely combined with the organic substances that neither dialysis nor electro-dialysis is sufficient to remove them from the residue of the gum. The chief constituents of agar ash are sulphuric acid and calcium, and a little silicic acid is also present. On boiling the agar solution under pressure, the sulphuric acid passes into an easily dialysable form. Simultaneously with this, the whole of the physico-chemical properties of the solution change, so that a causal connexion between the sulphur content and the power of forming jellies is deduced. Gelose-sulphuric acid is a typical constituent of agar, and in this the sulphuric acid is in all probability present as an ester. The mean molecular weight of this substance is about 9000. It is a monobasic acid and contains one atom of sulphur in each molecule. Agar jellies reach the maximum of their tenacity at the neutral point.

J. F. S.

**Preparation of Aliphatic Dialkylaminoalkyl Compounds.** FARBWERKE VORM. MEISTER, LUCIUS, & BRÜNING (*Brit. Pat.* 169185, addition to 167781 (cf. A., 1922, i, 529).—The condensation described in the main patent can be carried out by causing an alkali hydroxide to act on a mixture, in molecular proportions, of a dialkylhalogeno-alkylamine, and a substance of the general formula  $R\cdot CO\cdot CHR'\cdot X$  such as ethyl acetoacetate. Further, a purer product is obtained if the reaction mixture is mixed with benzene and shaken with ammonia before drying and distilling. Ethyl diethylaminoethylacetoacetate, prepared in this way from diethylchloroethylamine and ethyl acetoacetate, boils at 130—132°/10 mm.

G. F. M.

**New Compounds of Diamines. II.** PETER BERGELL (*Z. physiol. Chem.*, 1922, **123**, 280—289).—The following compounds

have been prepared from ethylenediamine and the necessary acid chloride:—*di-α-bromopropionylethylenediamine*,

white, glistening needles, m. p. 203°, *dichloroacetylenediamine*, long, rectangular or rhombic prisms, m. p. 171—172°, *di-β-naphthalenesulphonylethylenediamine*, fine needles. From pentamethylenediamine, *di-α-bromopropionylpentamethylenediamine*, and *di-β-naphthalenesulphonylpentamethylenediamine*, m. p. 147°. From these halogenated compounds, on heating with ammonia, the corresponding amino-derivatives are formed, but were not isolated. On treating that obtained from dibromopropionylpentamethylenediamine with β-bromopropionyl bromide, *di-α-bromopropionyl-dialanylethylenediamine*, m. p. 180°, is obtained. W. O. K.

**Dialkylaminoalkyl Compounds.** M. BOCKMÜHL and A. SCHWARZ (U.S. Pat. 1429922).—Ethyl α-(diethylaminoethyl)-acetoacetate, b. p. 132—135°/10 mm., is prepared by mixing 136 parts of diethylaminoethyl chloride with 130 parts of ethyl acetoacetate and gradually stirring into the mixture 57—58 parts of powdered alkali hydroxide, cooling, treating with benzene, shaking the benzene solution with ammonia, drying and distilling. As an alternative method, alkali hydroxide may be gradually introduced into diethylaminoethyl bromide hydrobromide and ethyl acetoacetate. The corresponding α-dimethyl ester, b. p. 124°/12 mm., may be similarly prepared from dimethylaminoethyl chloride. Ethyl diethylaminobutylacetoacetate, b. p. 138°/10 mm., is prepared from diethylaminochlorobutanol, ethyl acetoacetate, and powdered alkali hydroxide. CHEMICAL ABSTRACTS.

**β-Aminodicarboxylic Acids and Aminopolycarboxylic Acids.** C. MANNICH and ERIC GANZ (*Ber.*, 1922, 55, [B], 3486—3504).—In a previous communication (A., 1920, i, 719), Mannich and Kather have described the preparation of ω-dimethylamino-dimethylmalonic acid from methylmalonic acid, dimethylamine, and formaldehyde. The reaction is now shown to be of general applicability, occurring in accordance with the equation:

The reaction is generally effected by mixing concentrated solutions of formaldehyde and of a monosubstituted malonic acid which has been half neutralised by the requisite base and preserving the mixture in ice. In general, the new acid separates spontaneously or after addition of alcohol or acetone; if this is not the case, there is little likelihood of a successful preparation owing to the instability of the products. The nature of the substituent introduced into the malonic acid has but little influence on the course of the change, provided that it is aliphatic or fatty aromatic; with aromatic constituents, the primarily formed dicarboxylic acid suffers immediate loss of carbon dioxide. Secondary bases, such as dimethylamine and piperidine, are more suitable than primary bases or ammonia with which frequently more than one hydrogen atom becomes involved in the reaction.

The  $\beta$ -amino-dicarboxylic acids are generally unstable and decompose readily in substance or in solution with the production of  $\alpha$ -substituted acrylic acids. The change is conveniently effected by boiling them in neutral solution. It has not been found possible to discover conditions under which carbon dioxide is evolved without elimination of the basic group. On the other hand, the conversion of the aminodi- into the aminomono-carboxylic acid appears to be possible through the esters, since the dicarboxylic acids when treated with alcoholic hydrogen chloride give esters of the mono-carboxylic acids which can be hydrolysed by aqueous hydrochloric acids to the acid hydrochlorides. The place of the monosubstituted malonic acids may be taken by ethanetricarboxylic acid,  $\text{CH}(\text{CO}_2\text{H})_2 \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ , but not apparently by ethanetetra-carboxylic or methylenedimalonic acid. Cyanoacetic acid may also be used.

The following substances are described: *Dimethylaminomethyl-ethylmalonic acid*,  $\text{NMe}_2 \cdot \text{CH}_2 \cdot \text{C}(\text{CO}_2\text{H})_2$ , plates, m. p.  $101^\circ$  (decomp.), which is readily decomposed into  $\alpha$ -ethylacrylic acid, b. p.  $179-180^\circ$ . *Methylaminomethylethylmalonic acid*,

m. p. about  $136^\circ$  (decomp.), and its benzoyl derivative, plates, m. p.  $142^\circ$  (decomp.). *Dimethylaminomethylallylmalonic acid*, rhombic plates, m. p.  $85^\circ$  (decomp.), its chloroplatinate and  $\alpha$ -allyl-acrylic acid, b. p.  $76-78^\circ/16$  mm. (the barium, lead, and silver salts are described).  $\delta$ -Phenylpropyl- $\alpha$ -dimethylaminomethylmalonic acid,  $\text{CH}_2\text{Ph} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{C}(\text{CH}_2 \cdot \text{NMe}_2)(\text{CO}_2\text{H})_2$ , small, colourless needles, m. p. about  $115^\circ$  (decomp.) [from  $\delta$ -phenylpropylmalonic acid, dimethylamine, and formaldehyde], and  $\delta$ -phenyl- $\alpha$ -methyleneglutaric acid,  $\text{CH}_2\text{Ph} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{C}(\text{CH}_2) \cdot \text{CO}_2\text{H}$ , m. p.  $45^\circ$  (silver salt, leaflets). *Benzylidimethylaminomethylmalonic acid*, needles, m. p.  $88^\circ$ , and  $\alpha$ -benzylacrylic acid,  $\text{CH}_2 \cdot \text{C}(\text{CH}_2\text{Ph}) \cdot \text{CO}_2\text{H}$ , m. p.  $68^\circ$  [the latter acid yields a dibromide,  $\text{CH}_2\text{Ph} \cdot \text{CBr}(\text{CH}_2\text{Br}) \cdot \text{CO}_2\text{H}$ , needles, m. p.  $145^\circ$ ; it is oxidised by potassium permanganate in faintly alkaline solution to  $\alpha$ -benzylglyceric acid,  $\text{OH} \cdot \text{CH}_2 \cdot \text{C}(\text{OH})(\text{CH}_2\text{Ph}) \cdot \text{CO}_2\text{H}$ , prisms, m. p.  $127^\circ$ ]. *Benzylpiperidinomethylmalonic acid*,

decomp. about  $121^\circ$ , and its sparingly soluble lead and barium salts; the acid is converted by alcoholic hydrogen chloride at the atmospheric temperature into ethyl  $\alpha$ -benzyl- $\beta$ -piperidinopropionate hydrochloride,  $\text{C}_5\text{NH}_{10} \cdot \text{CH}_2 \cdot \text{CH}(\text{C}_6\text{H}_5) \cdot \text{CO}_2\text{Et} \cdot \text{HCl}$ , plates, m. p.  $185^\circ$ , which is hydrolysed by concentrated hydrochloric acid to  $\alpha$ -benzyl- $\beta$ -piperidinopropionic acid hydrochloride, small plates, m. p.  $146^\circ$ . *Benzylmethylaminomethylmalonic acid*, small needles, m. p. about  $150^\circ$  (decomp.), its benzoyl derivative, m. p. about  $138^\circ$  (decomp.), and nitroso-compound, plates, m. p. about  $122^\circ$  (decomp.); [the sodium salt of the acid is transformed by potassium cyanate into benzylmethylcarbamidomethylmalonic acid,

small plates, m. p. about  $98^\circ$  (decomp.), which when heated in boiling xylene passes into  $\alpha$ -benzyl- $\beta$ -methylcarbamidopropionic acid,  $\text{NH}_2 \cdot \text{CO} \cdot \text{NMe} \cdot \text{CH}_2 \cdot \text{CH}(\text{CH}_2\text{Ph}) \cdot \text{CO}_2\text{H}$ ; the latter substance is converted by boiling acetic anhydride into 2 : 4-diketo-5-benzyl-1-methyl-

hexahydropyrimidine,  $\text{CO} \begin{smallmatrix} \text{NH} - \text{CO} \\ \text{NMe} \cdot \text{CH}_2 \end{smallmatrix} \text{CH} \cdot \text{CH}_2 \cdot \text{Ph}$ , small needles, m. p. 78°]. Benzylallylaminomethylmalonic acid,  $\text{CH}_2 \cdot \text{CH} \cdot \text{CH}_2 \cdot \text{NH} \cdot \text{CH}_2 \cdot \text{C}(\text{CH}_2 \text{Ph})(\text{CO}_2\text{H})_2$ , needles, m. p. 138° (decomp.), and its sparingly soluble lead and barium salts.

According to experimental conditions, benzylmalonic acid is converted by ammonia and formaldehyde into iminobis-methyl-benzylmalonic acid,  $\text{NH}[\text{CH}_2 \cdot \text{C}(\text{CH}_2 \text{Ph})(\text{CO}_2\text{H})_2]_2$ , small plates, m. p. 107° (decomp.), or benzylaminomethylmalonic acid,

lustrous leaflets, m. p. about 148° (decomp.); either substance is transformed in boiling neutral aqueous solution into  $\alpha$ -benzylacrylic acid.

$\beta$ -Dimethylamino- $\alpha$ -phenylpropionic acid,  $\text{NMe}_2 \cdot \text{CH}_2 \cdot \text{CHPh} \cdot \text{CO}_2\text{H}$ , needles, m. p. 143°, prepared from phenylmalonic acid, dimethylamine, and formaldehyde at 0°, is transformed by being heated into atropic acid, m. p. 106°. Phenylmalonic acid, ammonia, and formaldehyde yield  $\beta$ -amino- $\alpha$ -phenylpropionic acid, which is isolated as the hydrochloride, m. p. 185°; it is converted by phenylacetyl chloride to a small extent into  $\beta$ -phenylacetyl-amino- $\alpha$ -phenylpropionic acid, small needles, m. p. 185°, the main product of the reaction being, however, phenylacetamide. Phenylmalonic acid, ammonium chloride, and formaldehyde give  $\beta$ -iminobis- $\alpha$ -phenylpropionic acid,  $\text{NH}(\text{CH}_2 \cdot \text{CHPh} \cdot \text{CO}_2\text{H})_2$ , which is isolated as the hydrochloride, m. p. 112°; it passes into atropic acid when boiled in neutral solution.

Phenacyldimethylaminomethylmalonic acid,

needles, m. p. about 148° (decomp.), and phenacylmethylaminomethylmalonic acid, m. p. 105° (decomp.), are obtained in the usual manner; the sparingly soluble lead and barium salts of the latter acid are mentioned.

Piperazine-1-propionic-4-isosuccinic acid,

leaflets, m. p. about 227° (decomp.), after becoming discoloured at 200°, is prepared from malonic acid, piperazine, and formaldehyde, and is converted by hot aqueous hydrochloric acid into piperazine-1:4-di- $\beta$ -propionic acid,

which is isolated as the dihydrochloride, m. p. 261–262° (decomp.).

Ethanetricarboxylic acid, dimethylamine, and formaldehyde yield  $\gamma$ -dimethylamino- $\beta\beta$ -dicarboxy-n-butyric acid,

needles, m. p. about 135° (decomp.), which passes in boiling aqueous solution by loss of carbon dioxide into  $\gamma$ -dimethylamino- $\beta$ -carboxy-n-butyric acid,  $\text{NMe}_2 \cdot \text{CH}_2 \cdot \text{CH}(\text{CO}_2\text{H}) \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ , m. p. 158°. The latter acid is transformed into itaconic acid by treatment of its crystalline methiodide with potassium hydroxide.

The action of formaldehyde on dimethylammonium cyanoacetate is accompanied by the evolution of carbon dioxide; the product of the action consists doubtless of  $\beta$ -dimethylaminopropionitrile,  $\text{NMe}_2\text{CH}_2\text{CH}_2\text{CN}$ . Its isolation could not be effected, but its presence is established by the formation of acrylic acid when the crude product is treated with hydrogen chloride.

H. W.

**A Synthesis of Aminohydroxydicarboxylic Acids.** C. MANNICH and M. BAUROTH (*Ber.*, 1922, 55, [B], 3504—3509).—A synthesis of  $\beta$ -aminodicarboxylic acids from monosubstituted malonic acids, formaldehyde, and amines has been described by Mannich and Kather (*A.*, 1920, i, 719) and Mannich and Ganz (preceding abstract). If, under otherwise similar conditions, the alkylmalonic is replaced by tartronic (hydroxymalonic) acid, aminohydroxydicarboxylic acids are produced. These, like the compounds described previously, are unstable substances, and when warmed with water undergo simultaneous decomposition in two directions; thus dimethylaminomethyltartronic acid becomes transformed on the one hand by simple loss of carbon dioxide into  $\beta$ -dimethylamino- $\alpha$ -hydroxypropionic acid, and, on the other, by loss of carbon dioxide and dimethylamine, into pyruvic acid.  $\beta$ -Dimethylamino- $\alpha$ -hydroxypropionic acid is not an intermediate compound in the latter change, since it is stable under the experimental conditions adopted.

*Dimethylaminomethyltartronic acid*,  $\text{OH}\cdot\text{C}(\text{CH}_2\cdot\text{NMe}_2)(\text{CO}_2\text{H})_2$ , plates, m. p. about  $115^\circ$  (decomp.), is prepared by the action of formaldehyde at  $0^\circ$  on a concentrated aqueous solution of tartronic acid which has been half neutralised by dimethylamine. It yields  $\beta$ -dimethylamino- $\alpha$ -hydroxypropionic acid,  $\text{NMe}_2\text{CH}_2\text{CH}(\text{OH})\cdot\text{CO}_2\text{H}$ , which is analysed in the form of its hydrochloride, rodlets, m. p.  $145$ — $146^\circ$ . *Methylaminomethyltartronic acid*,

aggregates of coarse needles, m. p. about  $153^\circ$  (decomp.), when rapidly heated, is similarly prepared from tartronic acid, formaldehyde, and methylamine and is converted by hot water and hydrochloric acid into  $\beta$ -methylamino- $\alpha$ -hydroxypropionic acid hydrochloride, transparent pyramids, m. p.  $155$ — $156^\circ$ . *Aminomethyltartronic acid*,  $\text{OH}\cdot\text{C}(\text{CH}_2\cdot\text{NH}_2)(\text{CO}_2\text{H})_2$ , coarse crystals, m. p. about  $138^\circ$  (decomp.), is decomposed by hot water into pyruvic acid in small amount;  $\beta$ -amino- $\alpha$ -hydroxypropionic acid does not appear to be produced. *Piperidinomethyltartronic acid* crystallises in leaflets, m. p. about  $190^\circ$  (decomp.).

H. W.

**The Carbamide Rearrangement.** TENNEY L. DAVIS and H. W. UNDERWOOD, jun. (*J. Amer. Chem. Soc.*, 1922, 44, 2595—2604).—It is shown that carbamide, thiocarbamide, and guanidine and their derivatives undergo the "urea rearrangement." Carbamide yields ammonia and isocyanic acid, and the other compounds yield derivatives of ammonia and of isocyanic acid. Such rearrangement forms the basis of a number of syntheses.  $s$ -Disubstituted aromatic carbamides may conveniently be prepared by

heating carbamide with primary aromatic amines. In the aliphatic series, the reaction succeeds, but the products are more difficult to isolate, and the process is being further studied. The similarity between guanidine and carbamide, and between cyanamide and isocyanic acid in respect to a number of their reactions is pointed out. It is considered that the polymerisation of cyanamide to dicyanodiamide, when its aqueous solution is evaporated, is believed to be a case of the "urea dearrangement."

The explanation of the formation of melamine, when aqueous ammonia and dicyanodiamide are heated together, previously given (A., 1922, i, 118), is probably wrong. A portion of the dicyanodiamide is hydrolysed by the action of the ammonia to yield, first, guanylcarbamide and later guanidine, and the latter dearranges to form cyanamide, which combines with the unaltered dicyanodiamide to yield melamine. W. G.

**Trihalogenated Pyvurins.** M. GARINO (*Gazzetta*, 1922, 52, ii, 207—220).—Various compounds analogous to Fischer's tribromopyvurin (A., 1887, 918) have been prepared, pyruvic acid being converted into the dichloro- or dibromo-derivative and this treated with carbamide in presence of sulphuric acid to give the dihalogenated pyvureide, which yields the trihalogenated pyvurin when subjected to the action of a halogen. The stability of these compounds, and also their solubility in water, 95% alcohol, or ether, diminish as the chlorine is replaced by bromine, and no derivative with more than one atom of iodine could be obtained. When treated carefully with dilute alkali solution, the trihalogenated pyvurins yield the corresponding analogues of chloroform, the readiness with which this decomposition occurs increasing as the atomic weight of the halogens present increases. Pharmacological experiments on mammals of various species show that, whereas trichloropyvurin passes almost unchanged through the organism, the tribromo-compound is decomposed with formation of bromoform and produces prolonged narcosis.

*Dichloropyvureide*,  $\text{CCl}_2\text{C} \begin{smallmatrix} \text{NH}\cdot\text{CO} \\ \text{CO}\cdot\text{NH} \end{smallmatrix}$ , prepared from dichloropyruvic acid, is a white, pulverulent substance, m. p.  $286^\circ$ , subliming unchanged at about  $170^\circ$ .

*Trichloropyvurin*,  $\text{CCl}_3\text{CO}\cdot\text{CO}\cdot\text{NH}\cdot\text{CO}\cdot\text{NH}_2$ , crystallises in soft, lustrous plates, m. p.  $242^\circ$  (decomp.), and gives the phenylcarbylamine reaction with potassium hydroxide and aniline; with potassium hydroxide and  $\beta$ -naphthol it gives a greenish-blue coloration and with thymol a reddish-violet coloration. It readily forms supersaturated solutions in water.

*Dichlorobromopyvurin*,  $\text{C}_4\text{H}_3\text{O}_3\text{N}_2\text{Cl}_2\text{Br}$ , forms lustrous, white scales, m. p.  $236^\circ$  (decomp.). *Chlorodibromopyvurin*,  $\text{C}_4\text{H}_3\text{O}_3\text{N}_2\text{ClBr}_2$ , forms white, lamellar crystals, m. p.  $238^\circ$  (decomp.). *Dichloriodopyvurin*,  $\text{C}_4\text{H}_3\text{O}_3\text{N}_2\text{Cl}_2\text{I}$ , forms yellow crystals, m. p. about  $230^\circ$  (decomp.), and begins to yield iodine vapour at about  $150^\circ$  or, if very slowly heated, at about  $170^\circ$ . *Dibromiodopyvurin*,

forms white crystals turning yellow in the light, m. p.  $197^{\circ}$  (decomp.), and begins to emit iodine at about  $105^{\circ}$ . T. H. P.

**Preparation of Chlorobromoiodypyurin.** M. GARINO and I. MUZIO (*Gazzetta*, 1922, 52, ii, 226—232).—Chloropyruvic acid (cf. Genvresse, *Bull. Soc. chim.*, 1892, [iii], 7, 83), prepared by the action of sulphuryl chloride on pyruvic acid, forms white, rhombohedral crystals ( $+H_2O$ ), m. p.  $55^{\circ}$ , and decomposes between  $122^{\circ}$  and  $155^{\circ}$ ; the anhydrous acid, m. p. about  $45^{\circ}$ , is very unstable. Chlorobromopyruvic acid,  $CHClBr\cdot CO\cdot CO_2H$ , forms white, tabular crystals, m. p.  $105^{\circ}$ .

Chlorobromopyruvide,  $CClBr\cdot C \begin{smallmatrix} < NH\cdot CO \\ CO\cdot NH \end{smallmatrix}$ , forms a light, white precipitate, and begins to sublime at about  $120^{\circ}$ . Chlorobromoiodypyurin,  $CClBr\cdot CO\cdot CO\cdot NH\cdot CO\cdot NH_2$ , prepared by treating the preceding compound with iodine in presence of iodic acid and carbon tetrachloride, forms white crystals, m. p.  $233^{\circ}$  (decomp.), and begins to emit iodine at  $160^{\circ}$ . It is highly stable in the dry state, but readily decomposes in solution, especially under the influence of light. In presence of potassium hydroxide, it gives a violet coloration with thymol and a blue coloration with  $\beta$ -naphthol; with potassium hydroxide and aniline, it forms phenylcarbylamine. When treated with potassium hydroxide under certain conditions, it yields ammonium oxalurate and chlorobromiodomethane, which is being investigated further. T. H. P.

**Electrolytic Dissociation of Dicyanodiamide in Aqueous Solution.** NAOTO KAMEYAMA (*J. Coll. Eng. Tokyo*, 1922, 11, 185—191).—By measuring the conductivity of solutions of sodium hydroxide and dicyanodiamide at  $25^{\circ}$ , the hydrolysis of sodium dicyanodiamide in 0.1 mol. solution was found to be 94.5%. In more dilute solutions, hydrolysis is almost complete. The dissociation constant at  $25^{\circ}$  is  $0.6 \times 10^{-14}$ . The basic properties of dicyanodiamide are very feeble, the hydrochloride, if it exists at all, being completely hydrolysed in aqueous solution. G. F. M.

**Attempts to Prepare Carbonyl Cyanide and a Method of Obtaining Unsaturated Amino-acids.** OTTO DIELS, HUGO GÄRTNER, and RICHARD KAACK (*Ber.*, 1922, 55, [B], 3439—3448).—Attempts are described to prepare carbonyl cyanide,  $CO(CN)_2$ , by the ozonisation of suitable derivatives of malononitrile; these, however, have not been completely successful. A synthesis of unsaturated amino-acids from ethyl cyanoethoxyacrylate has been effected.

Ethoxymethylenemalononitrile,  $OEt\cdot CH\cdot C(CN)_2$ , large, colourless crystals, m. p.  $65$ — $66^{\circ}$  after previous softening, is prepared by the protracted heating of a solution of malononitrile and ethyl orthoformate in acetic anhydride. It is converted by boiling water into hydroxymethylenemalononitrile, m. p.  $135^{\circ}$  (decomp.) [hydrochloride,  $C_4H_5ON_2Cl$ , lustrous needles, m. p.  $221^{\circ}$  (decomp.)], and by ammonia (25%) into aminomethylenemalononitrile, pale yellow crystals, m. p.

146°. Ozonisation of ethoxymethylenemalononitrile dissolved in glacial acetic acid under varied conditions of temperature and concentration has not led to conclusive results, but, in certain circumstances, a crystalline material has been isolated in very small amount, the properties of which are such as might be expected to be shown by carbonyl cyanide. Ozonisation of ethyl cyanoethoxyacrylate dissolved in ethyl acetate leads to the production of an ozonide which is decomposed by warm water with formation of oxalic acid. Benzylidenemalononitrile is unexpectedly resistant towards the action of ozone.

Malononitrile reacts energetically with acetaldehyde at 0° in the presence of a drop of piperidine, and gives 1:3-dimethylcyclobutane-2:2:4:4-tetranitrile,  $(\text{CN})_2\text{C} \begin{smallmatrix} < \text{CHMe} \\ < \text{CHMe} \end{smallmatrix} > \text{C}(\text{CN})_2$ , small, colourless needles, m. p. 184—185°. In the presence of ethyl alcohol, the same substances yield ethylidenebismalononitrile,  $\text{HMe}[\text{CH}(\text{CN})_2]_2$ , colourless, prismatic crystals, m. p. 113—114°, which is decomposed by warm water with formation of acetaldehyde. Methylenebismalononitrile, large prisms, m. p. 136—137°, is prepared by the action of formaldehyde (40%) on a solution of malononitrile in alcohol. It dissolves in boiling water to a clear solution from which spindle-like crystals, m. p. about 192—195° after darkening at about 130°, separate; the filtrate from these crystals, if again boiled for a short time, deposits lustrous leaflets, m. p. 231—233° after darkening at about 200°. The composition of the two compounds is identical, but their further investigation has not been possible owing to lack of material.

Ethyl ethoxymethylenecyanoacetate is converted by benzylamine in ethyl-alcoholic (95%) solution into ethyl  $\alpha$ -cyano- $\beta$ -benzylaminoacrylate,  $\text{CH}_2\text{Ph}\cdot\text{NH}\cdot\text{CH}:\text{C}(\text{CN})\cdot\text{CO}_2\text{Et}$ , thick, colourless needles, m. p. 103—104°, which is slowly transformed by a solution of sodium in boiling ethyl alcohol (96%) into  $\beta$ -benzylaminoacrylic acid,  $\text{CH}_2\text{Ph}\cdot\text{NH}\cdot\text{CH}:\text{CH}\cdot\text{CO}_2\text{H}$ , colourless, unctuous leaflets, m. p. 97—98°, b. p. 105—106°/12 mm. (the sodium and silver salts are described).  $\beta$ -Anilinoacrylic acid, m. p. 156°, is prepared similarly and in poor yield from ethyl cyanoanilinoacrylate.

Ethyl cyanoethoxyacrylate is converted by cautious treatment with hydrazine hydrate into ethyl cyanohydrazinoacrylate,

slender, colourless needles, m. p. 96—97°, which, with acetone, yields the compound,  $\text{CMe}_2\cdot\text{N}\cdot\text{NH}\cdot\text{CH}:\text{C}(\text{CN})\cdot\text{CO}_2\text{Et}$ , rhombohedra, m. p. 78—79°.

H. W.

**Possible Asymmetry of Aliphatic Diazo-compounds. III.**  
P. A. LEVENE and L. A. MIKESKA (*J. Biol. Chem.*, 1922, 54, 101—103).—When fused with benzoic acid, ethyl diazosuccinate yields ethyl benzoylmalate, b. p. 147—148°/3 mm., 143°/2 mm. The products from two preparations had  $[\alpha]_D^{25} +0.22^\circ$  and  $+0.12^\circ$ , respectively. The authors regard the rotations obtained as additional evidence of the existence of optically active diazosuccinic esters (cf. A., 1922, i, 818).

E. S.

***s*-Diisopropylhydrazine and its Derivatives. II. HARRY L. LOCHTE, WILLIAM A. NOYES, and JAMES R. BAILEY (*J. Amer. Chem. Soc.*, 1922, **44**, 2556—2567; cf. A., 1922, i, 329).—*s*-Di-**

**isopropylhydrazine** has been carefully purified and some of its physical constants have been redetermined with the following results: b. p. 124.5°/750 mm.,  $d_4^{20}$  0.7844,  $n_D^{20}$  1.4125. It gives an *oxalate*, m. p. 200°, and a *semicarbazide* derivative, m. p. 100°. If the dry hydrochloride is mixed with a 30% excess of dry powdered copper oxide in a stoppered flask and after a week the mixture is distilled, 2:2'-azopropane, b. p. 88.5°/750 mm.,  $d_4^{20}$  0.7408,  $n_D^{20}$  1.3890, is obtained. This compound is readily reduced to the symmetrical hydrazine, but weak oxidising agents have no effect on it. When left in contact with solid sodium or potassium hydroxides, it is partly converted into acetoneisopropylhydrazone.

*iso*Propylhydrazine,  $\text{CHMe}_2\text{NH}\cdot\text{NH}_2$ , b. p. 106—107°/750 mm., may be prepared by one of four methods, namely, hydrolysis of the *azo*-derivative, hydrolysis of acetoneisopropylhydrazone, direct reduction of an equimolecular mixture of acetone, hydrazine hydrate, and hydrochloric acid, or by hydrolysis of *isopropylsemicarbazide*. The third method, that of catalytic reduction, as in the case of the *s*-hydrazine, is the most practical one. The base is very unstable and is best isolated as its *hydrochloride*, m. p. 114°, and gives a *dibenzoyl* derivative, m. p. 161.5°, and a *phenylthiosemicarbazide*, m. p. 141.5°. When the free base is mixed with an equimolecular amount of dry acetone and an equal volume of absolute alcohol is added *acetoneisopropylhydrazone*, b. p. 132—134°,  $d_4^{20}$  0.8225,  $n_D^{20}$  1.4360, is obtained.

The *mononitroso*-derivative, b. p. 65—66°/6—8 mm.,  $d_4^{20}$  0.9440,  $n_D^{20}$  1.4420, of *s*-diisopropylhydrazine has been isolated and its sodium salt prepared.

It is suggested that some of the above methods may serve for the preparation of a number of *s*-secondary hydrazines, azoparaffins, monoalkylhydrazines, and mixed hydrazo- and azo-paraffins.

W. G.

**A New Method for the Introduction of an Ethyl Group. The Reaction between Organomagnesium Haloids and Ethyl Sulphate.** HENRY GILMAN and RACHEL E. HOYLE (*J. Amer. Chem. Soc.*, 1922, **44**, 2621—2626).—Ethyl sulphate reacts with organomagnesium haloids in which the group  $\text{MgX}$  is attached to carbon, oxygen, or nitrogen, and in all the cases examined this group was replaced by the ethyl group. The yields of the reaction in a number of cases were decidedly good, and the process should be of value, not only in synthetic chemistry, but also as a trustworthy method for the determination of the mechanism of certain reactions.

W. G.

**The Preparation and Properties of Trimethylstannane.** CHARLES A. KRAUS and WILLARD N. GREER (*J. Amer. Chem. Soc.*, 1922, **44**, 2629—2633).—Metallic sodium acts on trimethylstannic chloride in solution in liquid ammonia to give *sodium trimethylstannide*,  $\text{SnMe}_3\text{Na}$ , and this in turn is decomposed by ammonium

nitrate or chloride in the same solvent to give *trimethylstannane*,  $\text{SnMe}_3\text{H}$ , an oily liquid, b. p.  $60^\circ/750.3$  mm. The stannane is converted by the action of sodium in liquid ammonia to sodium trimethylstannide and with hydrochloric acid in aqueous solution it gives trimethylstannic chloride and hydrogen. W. G.

**The Mutual Influence of Substituents in Poly-substituted Benzenes.** E. KLEUCKER (*Ber.*, 1922, 55, [B], 2941).—The conclusion to which the author has been led that the mutual influence of substituents in ortho- and para-disubstituted benzenes is explicable in the same manner as that between groups at the ends of open-chain, conjugated unsaturated compounds (*A.*, 1922, i, 734) has been reached previously by Angeli (*Atti R. Accad. Lincei*, 1921, [v], 30, ii, 344), whose communication at the time of the author's work was not generally available. H. W.

**Equilibrium in the System *m*-Dinitrobenzene-Urethane.** NICOLAI ANTONOVICH PUSHIN and ALEXANDRA FIOLETOVA (*T.*, 1922, 121, 2822—2823).

**The Action of Thionyl Chloride on Substituted Benzene-sulphonyl Chlorides.** J. POLLAK and ZOSIA RUDICH (*Monatsh.*, 1922, 43, 209—224).—By the action of thionyl chloride on *m*-xylene-2:4-disulphonyl chloride, Pollak and Schadler obtained a substance which appeared to be 2:4-dichloro-*m*-phthaloyl chloride (*A.*, 1918, i, 497). To investigate this type of reaction further, the action of thionyl chloride on *o*- and *p*-toluenesulphonyl chlorides has now been studied. At  $200^\circ$ , *p*-toluenesulphonyl chloride is converted into *p*-chlorobenzylidene chloride, and at  $240^\circ$  almost quantitatively into *p*-chlorobenzoyl chloride; *o*-toluenesulphonyl chloride was converted into *o*-chlorobenzoyl chloride at  $240$ — $250^\circ$ , but under no conditions was *o*-chlorobenzylidene chloride formed. The possibility that chlorobenzotrichlorides are first formed and then hydrolysed by adventitious moisture is shown to be excluded. Toluene itself, on the other hand, gives benzotrichloride and no benzylidene chloride when heated in a sealed tube with thionyl chloride. By the action of thionyl chloride on *o*-xylene-4:6-disulphonyl chloride at  $250^\circ$ , a compound,  $\text{C}_8\text{H}_4\text{Cl}_6$ , m. p.  $78^\circ$ , was obtained, which may be a dichlorodi(dichloromethyl)benzene. At  $320^\circ$ , a crystalline compound, m. p.  $193$ — $196^\circ$ , was formed, which may be a more highly chlorinated derivative of *o*-xylene.

The dichloroisophthalic acid obtained by Pollak and Schadler by the action of thionyl chloride on *m*-xylene-2:4-disulphonyl chloride has been further investigated and found to be 2:6-dichloroisophthalic acid; its *methyl* ester has m. p.  $97$ — $98^\circ$ . The reaction appears, therefore, not to consist simply in replacement of chlorosulphonyl groups by chlorine, but a further rearrangement of the substituting groups is involved. At  $260^\circ$ , *m*-xylene-2:4-disulphonyl chloride is converted by thionyl chloride into a compound,  $\text{C}_8\text{H}_2\text{Cl}_8$ , m. p.  $113$ — $114^\circ$ , and at  $320^\circ$  into a still more highly chlorinated product.

*p*-Anisolesulphonyl chloride reacts with thionyl chloride at  $250^\circ$

to give a compound,  $C_7H_2OCl_6$ , m. p.  $214^\circ$ , probably *chloromethoxy-pentachlorobenzene*.  
E. H. R.

**Esters of the Hydroxyalkylarylamines. I. Acid Sulphuric Esters of the Simple Monohydroxyethylarylamines.** KENNETH HERBERT SAUNDERS (T., 1922, 121, 2667—2675).

**p-Cymene. IV. The Chlorination of 2-Amino-p-cymene.** ALVIN S. WHEELER and I. V. GILES (J. Amer. Chem. Soc., 1922, 44, 2605—2612; cf. A., 1919, i, 490; 1920, i, 751; 1922, i, 332).—When 2-acetamido-p-cymene is chlorinated in solution in carbon tetrachloride 5-chloro-2-acetylamido-p-cymene, m. p.  $109-111^\circ$ , is obtained and on hydrolysis yields 5-chloro-2-amino-p-cymene, b. p.  $240-250^\circ$ , from which the *hydrochloride*, the *sulphate*, and the *benzoyl* derivative, m. p.  $137.5^\circ$ , are prepared. When the hydrochloride is diazotised and the diazo-compound boiled with water, 5-chlorocarvacrol, b. p.  $158/52$  mm., is obtained, and when the diazo-compound is treated with cuprous cyanide in an excess of potassium cyanide and the resulting nitrile hydrolysed, it yields 4-chloro-2-methyl-5-isopropylbenzoic acid, m. p.  $125^\circ$ . When the hydrochloride is diazotised with half the equivalent amount of sodium nitrite, 2 : 2'-diazamino-5 : 5'-dichloro-p-cymene, m. p.  $135-137^\circ$ , is obtained.

The diazotised base couples readily with hydroxy-compounds. The resulting azo-dyes, in which a sulphonic group is present, act as direct dyes when employed in weak acetic acid solution. The others are developed dyes. The colours produced on wool and silk are fast to light and washing. The brilliancy of some is striking, and is undoubtedly due to the presence of the chlorine atom. The following are described. 4(5'-Chlorocarvacrylazo)phenol, m. p.  $196^\circ$ ; 4(5'-chlorocarvacrylazo)resorcinol, m. p.  $188^\circ$  (decomp.); 4(5'-chlorocarvacrylazo)salicylic acid, m. p.  $165^\circ$ , and its sodium salt; 4(5'-chlorocarvacrylazo)- $\alpha$ -naphthol, m. p.  $128^\circ$  (decomp.); 1(5'-chlorocarvacrylazo)- $\beta$ -naphthol, m. p.  $163^\circ$ ; 4(5'-chlorocarvacrylazo)-1-naphthol-2-sulphonic acid and its sodium salt; 2(5'-chlorocarvacrylazo)-1-naphthol-4-sulphonic acid, m. p.  $246^\circ$ , and its sodium salt; 1(5'-chlorocarvacrylazo)-2-naphthol-7-sulphonic acid, m. p.  $228^\circ$  (decomp.).

The constitution of the chloroaminocymene was proved as follows. The chloroacetamidocymene was oxidised by means of potassium permanganate in the presence of magnesium sulphate and yielded 5-chloro-2-acetamido-4-isopropylbenzoic acid, m. p.  $207-209^\circ$ , and this on hydrolysis gave 5-chloro-2-amino-4-isopropylbenzoic acid, m. p.  $159^\circ$ , giving a *hydrochloride*, m. p.  $178^\circ$ . Finally chloroaminocymene was diazotised and the product, by means of the Sandmeyer reaction, was converted into a dichloro-p-cymene, which, on oxidation in a sealed tube with nitric acid at  $180^\circ$  for ten hours, yielded 2 : 5-dichloroterephthalic acid, m. p.  $305^\circ$ .

W. G.

**$\alpha$ -Naphthylnitroamine and its Transformations.** E. BAMBERGER (Ber., 1922, 55, [B], 3383—3392).— $\alpha$ -Naphthylnitroamine differs from other members of this group, which do not contain a

chromophoric group and are colourless, in having a yellow colour. It is converted in a normal manner by mineral acids into 2-nitro- $\alpha$ -naphthylamine, but in alkaline solution it is transformed in an unusual manner into  $\beta$ -naphthaquinone- $\alpha$ -diazide, the reaction probably following the course:  $C_{10}H_7 \cdot NH \cdot NO \rightarrow C_{10}H_7 \cdot N \cdot NO \cdot OH \rightarrow C_6H_4 \cdot \begin{matrix} C(N_2 \cdot OH) \cdot C \cdot OH \\ | \\ CH=CH \end{matrix} \rightarrow C_6H_4 \cdot \begin{matrix} C(N_2) \cdot CO \\ | \\ CH=CH \end{matrix}$ . The peculiar behaviour of  $\alpha$ -naphthylnitroamine probably depends on the feebly acidic nature of its isonitroso-form, and its consequent ready formation by the hydrolysis of its salts and subsequent isomerisation to the quinonediazide.

[With LEO SCHLEIN.]—The conversion of  $\alpha$ -naphthylamine by successive diazotisation and oxidation with potassium ferricyanide into  $\alpha$ -naphthylnitroamine (cf. *Diss. Zürich*, 1894) is described in detail; the substance forms golden-yellow crystals, m. p. 123–124° when rapidly heated. The ammonium, lead, silver, calcium, and barium salts were prepared. The nitroamine is converted by sodium methoxide and methyl iodide into  $\alpha$ -naphthyl-N-methylnitroamine,  $C_{10}H_7 \cdot NMe \cdot NO_2$ , almost colourless, vitreous crystals, m. p. 54.5–55°.

$\alpha$ -Naphthylnitroamine is transformed by aqueous potassium hydroxide at the atmospheric temperature into  $\beta$ -naphthaquinone- $\alpha$ -diazide [ $\beta$ -hydroxy- $\alpha$ -diazonaphthalene], golden-yellow needles, m. p. 94–94.5°; preliminary experiments appear to show that a similar change does not take place with  $\beta$ -naphthylnitroamine.

Reduction of  $\alpha$ -naphthylnitroamine by sodium amalgam and water leads to the formation of naphthalene,  $\alpha$ -naphthylamine,  $\beta$ -naphthol, and ammonia. The production of  $\beta$ - (instead of  $\alpha$ -) naphthol is explained by the established relationship of  $\alpha$ -naphthylnitroamine to  $\beta$ -naphthaquinone- $\alpha$ -diazide.

$\alpha$ -Naphthylnitroamine is converted by nitrous acid in the presence of glacial acetic acid and subsequent treatment with an alkaline solution of  $\beta$ -naphthol into  $\alpha$ -naphthylazo- $\beta$ -naphthol, m. p. 228–229°.

**The Mechanism of the Bromination of Phenol in Aqueous Solution.** HARRY BAINES (T., 1922, 121, 2810–2813).

**Reduction of Polynitrophenols by Hydrogen Sulphide in Presence of Ammonia.** L. CHAS. RAIFORD (*Science*, 1921, 53, 218; cf. A., 1920, i, 156).—Reduction of 2:4-dinitrophenol by hydrogen sulphide and ammonia results, in contradiction of previous statements, in the production of isomeric substances. A. A. E.

**Methyl Sulphites of Secondary Aromatic Aliphatic Amines.** M. BOCKMÜHL and K. WINDISCH (U.S. Pat. 1426348).—*Sodium N-ethoxyphenylmethylaminomethyl sulphite*, m. p. 265°, is prepared by heating a mixture of formaldehyde solution, sodium hydrogen sulphite solution, *N*-methylphenetidine, and ethyl alcohol, collecting the product, and redissolving it in dilute ethyl alcohol. The corresponding ethyl derivative is similarly obtained from ethylphenetidine. *Sodium 1-phenyl-2:3-dimethylpyrazol-5-one-4-ethylaminomethyl sulphite*, m. p. (in water of crystallisation) 80–90°, is obtained by

adding a hot solution produced by the interaction of formaldehyde and sodium hydrogen sulphite to ethylaminoantipyrine, concentrating the solution in a vacuum, and purifying with aqueous acetone.

CHEMICAL ABSTRACTS.

**Researches on Residual Affinity and Co-ordination. XII. Cobaltammine and Ferric Lakes of Dinitrosoresorcinol.** GILBERT T. MORGAN and JOHN EWART MOSS (T., 1922, 121, 2857—2866).

**Preparation of New Guaiacol Compounds.** PHARM. AZEUTISCHE INDUSTRIE G. M. B. H. and RUDOLF HAUSCHKA (Austrian Pat. 86131; from *Chem. Zentr.*, 1922, iv, 710).—Silicon tetrachloride or other reactive silicon compound is allowed to react with guaiacol. From silicon tetrachloride and guaiacol, *dichlorodiguaiacysilicomethane*,  $\text{SiCl}_2(\text{O}-\text{C}_6\text{H}_4\cdot\text{OMe})_2$ , and *tetraguaiacysilicomethane*,  $\text{Si}(\text{O}-\text{C}_6\text{H}_4\cdot\text{OMe})_4$ , are obtained, and can be partly separated by distillation in a vacuum. The former is a viscid substance, but by solution in ether and evaporation can be obtained in colourless or greyish-green crystals; it is slowly decomposed by water with separation of silicic acid. The latter is a viscid liquid which by long heating in a vacuum gives off guaiacol vapour and forms *polyguaiacysilicon*,  $\text{Si}_{10}(\text{O}-\text{C}_6\text{H}_4\cdot\text{OMe})_{22}$ , a thick, honey-like syrup, b. p.  $220^\circ/20$  mm. G. W. R.

**Action of Aromatic Alcohols on Phenols in the Presence of Aluminium Chloride.** RALPH C. HUSTON (*Science*, 1920, 52, 206—207).—At relatively low temperatures, benzyl alcohol reacts with phenol in presence of aluminium chloride, giving a 40—50% yield of *p*-benzylphenol. The corresponding methyl and ethyl ethers were obtained in slightly better yields. A. A. E.

**Synthesis of certain Primary Alcohols from Unimolecular Formaldehyde and Grignard's Reagents.** KARL ZIEGLER and PAUL TIEMANN (*Ber.*, 1922, 55, [B], 3406—3416).—An extension of previous work (cf. A., 1921, i, 394).—An ethereal solution of 4-bromo-1-methylnaphthalene is treated successively with activated magnesium powder and gaseous formaldehyde whereby it is transformed into 1-methyl-4-hydroxymethylnaphthalene, small, colourless needles, m. p.  $74\text{--}75^\circ$  (*phenylurethane*, needles, m. p.  $103^\circ$ ); the yield is 40—50% of that theoretically possible, and is greatly dependent on the quality of the magnesium powder. The carbinol is oxidised by the necessary amount of dichromate and sulphuric acid to 1-methylnaphthalene-4-aldehyde, colourless needles, m. p.  $33\text{--}34^\circ$  (the corresponding bisulphite compound, semicarbazone, colourless leaflets, m. p.  $228^\circ$ , and azine, pale yellow crystals, m. p.  $166\text{--}167^\circ$ , are described). 1-Bromo-2-methylnaphthalene is transformed in a similar manner into 2-methyl-1-hydroxymethylnaphthalene, m. p.  $126\text{--}127^\circ$ , in 57% yield (*phenylurethane*, m. p.  $127\text{--}128^\circ$ ). The oxidation of the carbinol to the corresponding aldehyde could not be effected, a part of the original substance being completely burnt, whereas the residue remained unchanged. A solution of

the carbinol in glacial acetic acid is converted by hydrogen chloride and hydrogen bromide, respectively, into 2-methyl-1-chloromethyl-naphthalene, plates, m. p. 61—63°, and 2-methyl-1-bromomethyl-naphthalene, long needles, m. p. 87·5—89°. Reduction by sodium of the latter substance dissolved in moist ether gives 1:2-dimethyl-tetrahydronaphthalene, b. p. 123·5—124·5°/11 mm.,  $d_4^{20}$  0·9847,  $d_4^{25}$  0·9844,  $d_4^{30}$  0·988,  $n_D^{20}$  1·55298,  $n_D^{25}$  1·55762,  $n_D^{30}$  1·57082,  $n_D^{35}$  1·58195,  $n_D^{40}$  1·5593, which appears to contain a small proportion of the dihydro-compound.

$\beta\beta$ -Diphenylvinyl bromide, magnesium, and formaldehyde give  $\gamma$ -phenylcinnamyl ( $\gamma$ -diphenylallyl) alcohol,  $\text{CPh}_2\text{CH}\cdot\text{CH}_2\cdot\text{OH}$ , which is isolated through the corresponding hydrogen phthalate (the sodium salt of the latter is described). The alcohol has m. p. 61·5—63°, b. p. 205°/15 mm., 192°/10 mm. The corresponding acetate has b. p. 205°/15 mm., m. p. 36—37·5°,  $d_4^{20}$  1·1003,  $d_4^{25}$  1·1005,  $d_4^{30}$  1·091,  $n_D^{20}$  1·57980,  $n_D^{25}$  1·58592,  $n_D^{30}$  1·60189,  $n_D^{35}$  1·61734,  $n_D^{40}$  1·5817, whereas the benzoate has m. p. 89—90°. The alcohol is reduced by sodium and ethyl alcohol to  $\alpha\alpha$ -diphenylpropane, b. p. 140—141°/13 mm., 280°/760 mm.,  $d_4^{20}$  0·9951,  $d_4^{25}$  0·990,  $n_D^{20}$  1·56810,  $n_D^{25}$  1·5605. It is converted by hydrogen bromide in glacial acetic acid solution into  $\gamma$ -diphenylallyl bromide,  $\text{CPh}_2\text{CH}\cdot\text{CH}_2\text{Br}$ , m. p. 37—39°, which is transformed into  $\gamma$ -phenylcinnamaldehyde (semicarbazone, m. p. 214—215°).  $\gamma$ -Phenyl- $\beta$ -methylcinnamyl alcohol,  $[\text{CPh}_2\text{CMe}\cdot\text{CH}_2\cdot\text{OH}]$ , crystallises in coarse prisms, m. p. 68—69°, b. p. 184°/11 mm. (benzoate, colourless crystals, m. p. 116°). It is converted by concentrated sulphuric acid in the presence of glacial acetic acid into 1-phenyl-2-methylindene, m. p. 56·5°, its ability to suffer ring closure in this manner being in striking contrast to that of the lower homologue.

$p$ -Dibromobenzene is converted by magnesium and formaldehyde into  $p$ -bromobenzyl alcohol which is readily oxidised to  $p$ -bromobenzaldehyde, m. p. 57°, b. p. 105—110°/12 mm. The latter substance is transformed by magnesium methyl bromide into  $p$ -bromophenyl-methylcarbinol,  $\text{C}_6\text{H}_4\text{Br}\cdot\text{CHMe}\cdot\text{OH}$ , a colourless, viscous liquid, b. p. 133—134°/15 mm., 127—128°/11 mm.,  $d_4^{20}$  1·4690,  $d_4^{25}$  1·463,  $n_D^{20}$  1·56713,  $n_D^{25}$  1·57190,  $n_D^{30}$  1·58619,  $n_D^{35}$  1·59650,  $n_D^{40}$  1·5697. (The substance can also be prepared from magnesium  $p$ -bromophenyl bromide and acetaldehyde.) It is transformed by sodium hydrogen sulphate at 150° into  $p$ -bromostyrene,  $\text{C}_6\text{H}_4\text{Br}\cdot\text{CH}\cdot\text{CH}_2$ , a colourless, mobile liquid, b. p. 88·5—89·5°/16 mm., 83·5—84·5°/11 mm., m. p. 4·5°,  $d_4^{20}$  1·4098,  $d_4^{25}$  1·401,  $n_D^{20}$  1·59137,  $n_D^{25}$  1·59931,  $n_D^{30}$  1·61960,  $n_D^{35}$  1·63801,  $n_D^{40}$  1·5961.  $p$ -Bromobenzaldehyde and magnesium ethyl bromide give  $p$ -bromophenylethylcarbinol, b. p. 138—139°/11 mm.,  $d_4^{20}$  1·4085,  $d_4^{25}$  1·4084,  $d_4^{30}$  1·404,  $n_D^{20}$  1·55779,  $n_D^{25}$  1·56227,  $n_D^{30}$  1·57505,  $n_D^{35}$  1·58577,  $n_D^{40}$  1·5607, which is converted by sodium hydrogen sulphate into  $p$ -bromopropenylbenzene,  $\text{C}_6\text{H}_4\text{Br}\cdot\text{CH}\cdot\text{CHMe}$ , m. p. 35°, b. p. 108—110°/11 mm., 238—239°/atmospheric pressure,  $d_4^{20}$  1·3309,  $d_4^{25}$  1·356,  $n_D^{20}$  1·57746,  $n_D^{25}$  1·58391,  $n_D^{30}$  1·60372,  $n_D^{35}$  1·62159,  $n_D^{40}$  1·5934. Magnesium  $p$ -bromophenyl bromide and acetone give the expected carbinol, which was

not isolated in the homogeneous condition; it is transformed into *p*-bromoisopropenylbenzene,  $C_6H_4Br-CMe:CH_2$ , b. p.  $110^\circ/11$  mm.  $228^\circ/\text{atmospheric pressure}$ , m. p.  $11^\circ$ ,  $d_4^{20}$  1.3592,  $d_4^{25}$  1.350,  $n_D^{20}$  1.57721,  $n_D^{25}$  1.58346,  $n_D^{30}$  1.60497,  $n_D^{35}$  1.62089,  $n_D^{40}$  1.5835.

The brominated styrenes could only be caused to react incompletely with magnesium. H. W.

**Some Condensation Reactions with Di-*p*-dimethylaminobenzhydrol (Michler's Hydrol).** MARSTON TAYLOR BOGER and A. RUDERMAN (*J. Amer. Chem. Soc.*, 1922, **44**, 2612—2621).—Di-*p*-dimethylaminobenzhydrol (Michler's hydrol) condenses with the imides of succinic and phthalic acids to give the corresponding leucauramines, which on hydrolysis by alkali give the amic acids. The condensation may be carried out in either alcoholic solution or concentrated sulphuric acid. Under these conditions, succinimide gives *succinyl-leucauramine*, m. p.  $151^\circ$  (corr.). With nitrous acid, this yields *succinyl-dinitroleucauramine*, m. p.  $94-96^\circ$  (decomp.), and on hydrolysis gives *di-p-dimethylaminobenzhydrysuccinamic acid*, m. p.  $170^\circ$ . Phthalimide and Michler's hydrol give in alcoholic solution *phthalyl-leucauramine* in its stable form, m. p.  $186.7^\circ$  (corr.), whilst, if the condensation takes place in concentrated sulphuric acid, a labile form, m. p.  $90^\circ$ , is obtained and on heating is converted into the stable form. When oxidised with lead peroxide this compound gives *phthalyl-leucauraminocarbinol*, m. p.  $176^\circ$  (corr.). *Dinitrophthalyl-leucauramine*, m. p.  $104^\circ$  (decomp.), and *di-p-dimethylaminobenzhydrylphthalamic acid*, m. p.  $163.8^\circ$  (decomp., corr.), were prepared. The amic acid when oxidised by lead peroxide gave the corresponding *carbinol*, m. p.  $187^\circ$  (corr.). Michler's hydrol did not condense with phthalimidine, but with phthalide gave *di-bis-dimethylaminobenzhydrylphthalide*, m. p.  $201^\circ$  (corr.). A condensation product was not obtained from 4-nitrophthalimide, but 3-aminophthalimide yielded *3-leucauraminylphthalyl-leucauramine*, m. p.  $219-220^\circ$  (corr.).

Anthraquinone, its  $\alpha$ - or  $\beta$ -amino-derivatives, alizarin, thiocarbamide, or benzoylenecarbamide failed to react with the hydrol under the experimental conditions, but dehydrothio-*p*-toluidine condensed readily with the hydrol in alcoholic solution to give *2-di-p-dimethylaminobenzhydrylbenzthiazole*, m. p.  $190-191^\circ$  (corr.).

In alcoholic solution, "saccharin" gives a deep blue coloration with the hydrol even in dilute solution, and this reaction appears to be a delicate test for either compound. W. G.

**Solubility. VII. The Solubility of Salts of Aromatic Acids.** FRITZ EPHRAIM (*Ber.*, 1922, **55**, [B], 3472—3486; cf. A., 1922, ii, 574, and earlier abstracts).—The communication is the first of a series devoted to a study of the solubilities of metallic salts of organic acids and is confined to a qualitative survey of the field. Aqueous solutions of the sodium salts of seventy-three carboxylic or sulphonic acids, generally normal in concentration, are mixed at the atmospheric temperature with equivalent quantities of normal solutions of barium, strontium, calcium, and mercuric

chlorides, magnesium, zinc, ferrous, manganese, cobalt, nickel, copper, and cadmium sulphates, lead and silver nitrates, and the gradual or immediate formation of precipitates or their failure to appear is recorded. The acids used are benzoic, phenylacetic, cinnamic,  $\beta$ -naphthoic, phthalic, naphthalic, *o*- and *p*-chlorobenzoic, 4-chlorophthalic, salicylic, 2- and 4-hydroxy-*m*-toluic, 3-hydroxy-*p*-toluic, 3- and 1-hydroxy- $\beta$ -naphthoic, 3 : 5-dihydroxybenzoic, *p*-hydroxybenzoic, *p*-methoxybenzoic, *o*-benzoylbenzoic, *o*-*p*-toluoylbenzoic, *o*-*m'*-nitro-*p'*-toluoylbenzoic, *o*- $\alpha$ -naphthoylbenzoic, *o*- and *p*-nitrobenzoic, 4-nitro-2-hydroxybenzoic, 5- and 4-chloro-2-nitrobenzoic, 2-nitro-6-hydroxybenzoic, 3-nitro-4-methoxybenzoic, 4-chloro-3 : 5-dinitrobenzoic, *o*-, *m*-, and *p*-aminobenzoic, 4-amino-2-hydroxybenzoic, and 3-amino-4-methoxybenzoic. The following sulphonic acids are employed: benzene-, 2 : 4- and 3 : 4-dimethylbenzene-,  $\alpha$ - and  $\beta$ -naphthalene-, 2 : 5- and 3 : 4-dichlorobenzenene-, 1-chloronaphthalene-, 5-dibromonaphthalene-2-, *p*-hydroxybenzenene-, 5- and 4-hydroxynaphthalene-1-, 6-hydroxynaphthalene-2-, 5- and 3-nitro-2-methylbenzene-, 4-chloro-3-nitrobenzene-, 3 : 4-dichloro-5-nitrobenzene-, 5-nitronaphthalene-1-, 6-nitronaphthalene-2-, 3 : 5-dinitro-4-methylbenzene-, 3 : 5-dinitro-2 : 4-dimethylbenzene-, and 2-chloro-3 : 5-dinitrobenzene-, sulphanilic, 4- and 3-sulphobenzoic, and 3-sulpho-4-hydroxybenzoic acids. Benzene-1 : 3-di-, naphthalene-2 : 5-, -2 : 7-, and -1 : 5-di-, 1-nitronaphthalene-3 : 6-di-, dibromonaphthalene-2 : 7-di-, 2 : 6-dinitrobenzene-1 : 4-di-, 1-carboxybenzene-2 : 4-di-, naphthalene-1 : 3 : 6-tri-, 1-chloronaphthalene-3 : 6 : 8-tri-, 2-chloronaphthalene-3 : 6 : 8-tri-, and 1-nitronaphthalene-3 : 5 : 7-tri-sulphonic acids are also used.

The barium, lead, and silver salts of the carboxylic acids are without exception sparingly soluble, as are those of copper, except in two cases in which the acids contain vicinal carboxyl groups. The precipitates are usually caseous or voluminous, whereas those of other salts are crystalline. This property appears to be constitutional and not simply attributable to the rapidity of the separation. In many cases, the separation of the precipitates occurs relatively very slowly, although the substances once formed are frequently very sparingly soluble. The phenomenon can scarcely be attributed to simple supersaturation, and it appears more likely that an equilibrium between true and complex or pseudo-salt exists in the solutions. In certain cases in which the initial salt form is sparingly soluble, this change is very obvious. Thus, for example, cadmium phenylacetate is immediately precipitated, but speedily re-dissolves and subsequently crystallises in a different form. Similar observations are recorded with the cadmium and copper salts of 4-hydroxy-*m*-toluic acid, the two varieties of the copper salt being further distinguished by their respective brown and green colours. Further confirmation of the existence of two distinct types of salts is found in the observation that the strontium salts in respect of solubility do not by any means always fall into line between the corresponding barium and calcium salts. Frequently the equilibrium between the two forms is only slowly established; this is well illustrated by the zinc,

manganese, and cobalt salts of naphthalic acid. The observation that separation is expedited by warming the solutions is regarded as strong evidence that a chemical reaction is here involved and that the phenomenon is not simply one of crystallisation.

The great solubility of the magnesium salts, which in many cases exceeds that of the sodium salts, is remarkable. The mercuric salts are generally freely soluble and are only precipitated when the parent acid forms a complete series of sparingly soluble salts or possibilities exist for the formation of internal complexes. The salts of zinc, manganese, ferrous iron, cobalt, nickel, and cadmium have medium solubilities; of these, the cadmium and to a less extent the zinc compounds tend to have the lowest solubilities and to approximate in their behaviour to the copper salts.

The influence of the organic residue on the solubility of the salts is discussed at considerable length. The observations, however, are of a preliminary nature.

The salts of the sulphonic acids are generally more freely soluble than those of the corresponding carboxylic acids. In this respect, the behaviour of naphthalene- $\beta$ -sulphonic acid is altogether exceptional, since its salts, in particular the magnesium compound, are distinguished by their sparing solubility (cf. A., 1921, 1, 508). The introduction of a nitro-group into the molecule appears to increase the solubility of the salts, but the effect is not further enhanced by the introduction of a second nitro-group. As in the case of the carboxylic compounds, the barium and lead salts are generally the most sparingly soluble, whereas the silver salts of the sulphonic acid are relatively soluble. The mercuric salts are, in general, freely soluble, whilst a great increase in solubility is noted in the case of the copper salts. The sodium salts in many cases do not dissolve freely.

The solubility of the salts derived from acids containing a sulphonic and a carboxyl group resembles in general that of the simple sulphonic acid. The introduction of a second sulphonic group into the molecule does not further increase the solubility of the salts.

H. W.

**Preparation of Phenylglycine-*o*-carboxylic Acid.** HERBERT L. HALLER (*J. Ind. Eng. Chem.*, 1922, 14, 1040—1044).—The reaction between anthranilic acid and chloroacetic acid for the preparation of phenylglycine-*o*-carboxylic acid was studied. The best yields were obtained under the following conditions: Concentration, 25 g. of anthranilic acid in 200 c.c. of water. Ratio, 2 mols. of anthranilic acid to 1 mol. of chloroacetic acid. Condensing agent, 2.33 mols. of sodium carbonate to 1 mol. of chloroacetic acid. Temperature, 90°. Time of reaction, 1 hour. The use of an alkali carbonate as a condensing agent gives a better yield than an equivalent amount of an alkali hydroxide.

H. C. R.

**Preparation of Allyl *p*-Aminobenzoate.** SOCIETY FOR CHEMICAL INDUSTRY IN BASLE (Swiss Pat. 92300; from *Chem. Zentr.*, 1922, iv, 711; cf. Adams and Volweiler, A., 1921, i, 416).—

Compounds containing the *p*-nitrobenzoyl group are allylated and the allyl *p*-nitrobenzoate is reduced. For example, *p*-nitrobenzoyl chloride is heated with allyl alcohol at about 80°, or *p*-nitrobenzoic acid is esterified in the presence of hydrogen chloride. The allyl *p*-nitrobenzoate thus obtained is a light yellow oil crystallising on cooling, having m. p. 30° and b. p. 146–152°/3 mm. Allyl *p*-aminobenzoate obtained by reduction of the latter compound forms almost colourless needles, m. p. 54°. It is a local anæsthetic.

G. W. R.

**Preparation of Complex Silver Compounds.** F. HOFFMANN-LA ROCHE & Co. (D.R.-P. 1356912, Swiss Pat. 90809, 91108, and 91109; from *Chem. Zentr.*, 1922, iv, 711; cf. Myers, A., 1921, i, 843).—Organic or inorganic silver salts are allowed to react with thio-acyl derivatives of aromatic amines. *α*-Thiolacetylamidophenol, an amorphous, yellow powder, m. p. 105°, from chloroacetylamidophenol and sodium persulphide, is allowed to react with silver nitrate solution. The silver *α*-thiolacetylamidophenol obtained contains 37.2% of silver and gives no precipitate with sodium chloride, hydrogen sulphide, or ammonium sulphide solutions. From sodium *α*-thiolacetylamidosalicylate, silver sodium *α*-thiolacetylamidosalicylate is obtained. *α*-Thiolacetylamidosalicylic acid, obtained from chloroacetylamidosalicylic acid and sodium persulphide, is a light yellow powder, m. p. 223°. It gives a sodium salt. Similar products are obtained by the action of silver nitrate on the sodium salts of thiolisovalerylamidosalicylic acid and thiolpropionylamidosalicylic acid, respectively. The latter compound has m. p. 226°. These acids are prepared by the action of sodium persulphide on bromoisovalerylamidosalicylic acid and bromopropionylamidosalicylic acid, respectively.

G. W. R.

**The Resolution of Phenoxypropionic Acid and *o*-Nitrophenoxypropionic Acid into their Active Components.** E. FOURNEAU and G. SANDULESCO (*Bull. Soc. chim.*, 1922, [iv], 31, 888–893).—In resolving acids into their optical isomerides, the choice of yohimbine as a base leads to the formation of salts which crystallise readily and are separable without difficulty. Details are given of the separation of the phenoxypropionic acids as salts of yohimbine and of the *o*-nitrophenoxypropionic acids as salts of yohimbine and of cinchonine. In both cases the active form of the acids melt at a lower temperature than the racemic mixtures; *d*- and *l*-phenoxypropionic acids have m. p. 87°, the mixture 115°; the corresponding temperatures for *o*-nitrophenoxypropionic acid being 111–112° and 157°.

H. J. E.

**Ethyl Phenylpyruvate.** II. H. GAULT and R. WEICK (*Bull. Soc. chim.*, 1922, [iv], 31, 993–1026; cf. A., 1922, i, 1024).—Various reactions of the three isomeric forms of ethyl phenylpyruvate were studied and grouped according to whether they were (a) different in the case of the enolic and ketonic forms, or (b) common to all three forms. Among the former are the color-

ation obtained in presence of ferric chloride, the formation of additive bromine derivatives, the addition of phenylcarbimide yielding the phenylurethane, and the action of hydrochloric acid, which reactions the authors regard as fundamental for distinguishing between the  $\alpha$ - and  $\beta$ - and the  $\gamma$ -forms. The reactions common to all three isomerides include formation of esters, lactonisation, and condensation. An attempt to investigate the isomerism of ring-substituted derivatives of ethyl phenylpyruvate was abandoned owing to the difficulty of preparing these substances. The refractive indices of the isomerides were found to be;  $\beta$ ,  $n_D^{20}$  1.49735,  $\gamma$ ,  $n_D^{20}$  1.49821; the value for the  $\alpha$ -ester was not determined by reason of the rapid oxidation of the substance in air. Theoretical consideration of the results indicates that the  $\beta$ -form is enolic, and on chemical grounds the  $\alpha$ -ester is considered to be similar, the two being stereoisomerides; it is not possible, as yet, to decide which is the *cis* and which the *trans* form. The  $\gamma$ -ester has, on theoretical grounds, the ketonic form.

The following substances do not appear to have been previously described: *Ethyl  $\beta$ -bromophenylpyruvate*,  $\text{CHPhBr}\cdot\text{CO}\cdot\text{CO}_2\text{Et}$ , a mobile, yellow liquid of characteristic odour, b. p. 182—184.5°/20 mm.; *Ethyl  $\alpha\beta$ -dibromo- $\alpha$ -hydroxy- $\beta$ -phenylpropionate*,

a yellow, crystalline solid, m. p. not determined, as the substance is too unstable: it is stated that this is the first instance of the isolation of a brominated enolic compound; *Ethyl  $\alpha$ -acetoxy- $\beta$ -phenylpropionate*, a colourless oil of pleasant odour, b. p. 161—163°/15 mm.; *Ethyl  $\alpha$ -benzyloxy- $\beta$ -phenylpropionate*, yellow oil, b. p. 225—226°/15 mm.; *Ethyl  $\alpha$ -acetoxy-*cinnamate**, white crystals, m. p. 33.5°; *Ethyl  $\alpha$ -benzyloxy-*cinnamate**, white needles, m. p. 87°;  *$\alpha$ -Keto- $\beta$ -phenyl- $\gamma$ -benzylbutyrolactone- $\gamma$ -carboxylamide*,

white crystals, m. p. 229°; *2-benzylidene-1:4-dihydroquinazalone*,  $\text{C}_6\text{H}_4 \begin{array}{c} \diagup \text{NH}\cdot\text{C}\cdot\text{CHPh} \\ \diagdown \text{NH}\cdot\text{CO} \end{array}$ , yellowish-white crystals, m. p. 210°.

H. J. E.

**Preparation of an  $\alpha\beta$ -Tetrahydronaphtholcarboxylic Acid and its Ester and Acyl Derivative.** TETRALIN G. M. B. H. (D.R.-P. 357663; from *Chem. Zentr.*, 1922, iv, 761).—An anhydrous alkali salt of  $\alpha\beta$ -tetrahydronaphthol is treated with carbon dioxide at temperatures above 100°. After acidification, the resulting product is changed into esters or acyl derivatives by the usual methods. The potassium salt of  $\alpha\beta$ -tetrahydronaphthol, freed from water in a stream of hydrogen at 150—160°, is treated with carbon dioxide under pressure for several hours at 160—170°. After one molecule of carbon dioxide has been absorbed, the product is dissolved in water and acidified with hydrochloric acid. The  $\beta$ -tetrahydronaphthol- $\alpha$ -carboxylic acid thus obtained forms colourless needles, m. p. 177—178°. It gives a deep blue coloration with ferric chloride. The methyl ester has b. p. 184—185°/20 mm.; it

has an odour like that of ethyl acetoacetate, and forms a crystalline mass on keeping. By the action of acetic anhydride on the carboxylic acid at  $100^{\circ}$  in the presence of sulphuric acid,  $\beta$ -acetoxytetrahydronaphthalene-o-carboxylic acid, m. p.  $142-143^{\circ}$ , is obtained.

G. W. R.

**Certain Acidic Derivatives of "Dinitriles" and  $\beta$ -Aminocrotonic Esters.** ERICH BENARY and MARTIN ROSENFELD (*Ber.*, 1922, 55, [B], 3417-3429; cf. Benary and Schmidt, A., 1921, i, 776).—In continuation of previous work, the introduction of the phenoxyacetyl group into imidoacetonitrile, imidobenzoylacetonitrile, and imidotoluoylacetonitrile has been investigated. The use of the ester in the presence of sodium ethoxide leads to the production of a *N*-derivative, whereas *C*-compounds are produced from the acid chloride in the presence of pyridine. The condensation of the ester with these substances in the presence of potassium ethoxide has been described by Meyer (A., 1914, i, 996), but evidence is now adduced to show that his conception of the products as *C*-derivatives is incorrect.

Whereas in the previous instances investigated the production of uniform *C*- or *N*-derivatives has been observed according to the mode of procedure, it is found that cinnamoyl chloride and diacetonitrile give a mixture of about equal quantities of the two isomerides, whereas cinnamic ester and sodium ethoxide give only the *N*-derivative.  $\beta$ -Amino- $\alpha$ -phenoxyacetylcrotononitrile,

slender, colourless needles, m. p.  $167^{\circ}$ , is prepared by the action of phenoxyacetyl chloride on imidoacetylacetonitrile in anhydrous ethereal solution in the presence of pyridine. It is converted by *N*-sodium hydroxide solution into  $\beta$ -hydroxy- $\alpha$ -phenoxyacetylcrotononitrile,  $\text{OH}\cdot\text{CMe:C(CO}\cdot\text{CH}_2\cdot\text{OPh)}\cdot\text{CN}$ , almost colourless needles, m. p.  $138^{\circ}$ , the enolic nature of which is established by the isolation of the green copper salt.  $\beta$ -Amino- $\alpha$ -phenoxyacetylcrotononitrile is converted by phenylhydrazine into 4-cyano-1-phenyl-5-phenoxyethyl-3-methylpyrazole,  $\text{CMe}\cdot\text{C}\begin{smallmatrix} \text{C(CN)} \\ \text{N}\cdot\text{NPh} \end{smallmatrix}\cdot\text{C}\cdot\text{CH}_2\cdot\text{OPh}$ , colourless needles, m. p.

$73-74^{\circ}$ , which is also prepared by the action of phenylhydrazine on  $\beta$ -hydroxy- $\alpha$ -phenoxyacetylcrotononitrile in acetic acid solution. *N*- $\beta$ -Phenoxyacetylamidocrotononitrile,  $\text{OPh}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CN}$ , m. p. ( $\alpha$ -form)  $96^{\circ}$ , ( $\beta$ -form)  $123^{\circ}$  (cf. Meyer, *loc. cit.*), is decomposed by *N*-sodium hydroxide solution with the formation of phenoxyacetic acid, and by phenylhydrazine in acetic acid solution with production of phenoxyacetic acid phenylhydrazide.

$\beta$ -Amino- $\alpha$ -phenoxyacetylcinnamonitrile,

glassy, hexagonal plates, m. p.  $152^{\circ}$ , is prepared from imidobenzoylacetonitrile, pyridine, and phenoxyacetyl chloride in the presence of ether, and is transformed into  $\beta$ -hydroxy- $\alpha$ -phenoxyacetylcinnamonitrile,  $\text{OH}\cdot\text{CPh:C(CO}\cdot\text{CH}_2\cdot\text{OPh)}\cdot\text{CN}$ , lustrous leaflets, m. p.  $118^{\circ}$ . With phenylhydrazine in acetic acid solution (50%), it gives 4-cyano-1:3-diphenyl-5-phenoxyethylpyrazole, slender, colourless

needles, m. p. 158°.  $\beta$ -Phenoxyacetylamidocinnamionitrile,  $\text{OPh}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{CPh}\cdot\text{CH}\cdot\text{CN}$ , m. p. ( $\alpha$ -form) 95° (Meyer, *loc. cit.*, gives 87°), m. p. ( $\beta$ -form) 114°, is converted by *N*-sodium hydroxide solution into phenoxyacetic acid, and by phenylhydrazine into phenoxyacetic hydrazide. The product obtained by coupling the  $\beta$ -variety with diazobenzene chloride in alcoholic solution has m. p. 140° (Meyer, *loc. cit.*, gives 110°), and appears to have the composition  $\text{C}_{20}\text{H}_{18}\text{O}_2\text{N}_4$ ; its nitrogen content is greater than that found by Meyer.

$\beta$ -Amino- $\alpha$ -phenoxyacetyl- $\beta$ -*p*-tolylacrylonitrile,  
 $\text{C}_6\text{H}_4\text{Me}\cdot\text{C}(\text{NH}_2)\cdot\text{C}(\text{CO}\cdot\text{CH}_2\cdot\text{OPh})\cdot\text{CN}$ ,

large, colourless needles, m. p. 178°,  $\beta$ -hydroxy- $\alpha$ -phenoxyacetyl- $\beta$ -*p*-tolylacrylonitrile,  $\text{C}_6\text{H}_4\text{Me}\cdot\text{C}(\text{OH})\cdot\text{C}(\text{CO}\cdot\text{CH}_2\cdot\text{OPh})\cdot\text{CN}$ , colourless crystals, m. p. 141°, and 4-cyano-1-phenyl-3-*p*-tolyl-5-phenoxy-methylpyrazole, long needles, m. p. 167°, are obtained by similar methods.  $\beta$ -Phenoxyacetyl-amido- $\beta$ -*p*-tolylacrylonitrile, m. p. 148° (cf. Meyer, *loc. cit.*), is decomposed by sodium hydroxide or phenylhydrazine in the manner described for the analogous *N*-compounds.

Ethyl chloroformate, imidoacetylacetonitrile, and pyridine give an unstable substance,  $\text{C}_{12}\text{H}_{15}\text{O}_2\text{N}_3$ , a pale yellow, crystalline powder, m. p. 129–130° (decomp.). It is decomposed by boiling sodium hydroxide solution with the evolution of ammonia and pyridine. When preserved in the presence of water or alcohol, it forms a yellowish-red powder, decomp. 265–280°.

Imidoacetylacetonitrile, cinnamoyl chloride, and pyridine in the presence of ether yield a mixture of  $\beta$ -amino- $\alpha$ -cinnamoylcrotononitrile,  $\text{NH}_2\cdot\text{CMe}\cdot\text{C}(\text{CO}\cdot\text{CH}\cdot\text{CHPh})\cdot\text{CN}$ , colourless needles, m. p. 198–199°, and  $\beta$ -cinnamoylaminocrotononitrile,

$\text{CHPh}\cdot\text{CH}\cdot\text{CO}\cdot\text{NH}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CN}$ ,

colourless, quadratic plates, m. p. 191–192°. The latter substance is transformed by *N*-sodium hydroxide solution into ammonia and cinnamic acid, and by bromine in the presence of chloroform into  $\beta$ - $\alpha'$ -bromocinnamoylaminocrotononitrile,

$\text{CHPh}\cdot\text{CBr}\cdot\text{CO}\cdot\text{NH}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CN}$ ,

a colourless, crystalline powder, m. p. 144–145°.  $\beta$ -Amino- $\alpha$ -cinnamoylcrotononitrile is converted by sodium hydroxide solution into  $\beta$ -hydroxy- $\alpha$ -cinnamoylacetone,  $\text{OH}\cdot\text{CMe}\cdot\text{C}(\text{CO}\cdot\text{CH}\cdot\text{CHPh})\cdot\text{CN}$  (enolic form), sulphur-yellow needles, m. p. 130°, and by phenylhydrazine into 4-cyano-1-phenyl-5-styryl-3-methylpyrazole, slender, colourless needles, m. p. 134°.  $\beta$ -Amino- $\alpha$ -cinnamoylcrotononitrile dibromide,  $\text{CH}_3\cdot\text{C}(\text{NH}_2)\cdot\text{C}(\text{CN})\cdot\text{CO}\cdot\text{CHBr}\cdot\text{CHBr}\cdot\text{Ph}$ , crystallises in slender needles, m. p. 220° (decomp.) after darkening at 205°.

$\beta$ -Amino- $\alpha$ -cinnamoylcinnamionitrile,

$\text{NH}_2\cdot\text{CPh}\cdot\text{C}(\text{CO}\cdot\text{CH}\cdot\text{CHPh})\cdot\text{CN}$ ,

long, colourless needles, m. p. 173° (prepared from imidobenzoylacetoneitrile, cinnamoyl chloride, and pyridine) is converted in the usual manner into  $\beta$ -hydroxy- $\alpha$ -cinnamoylcinnamionitrile,

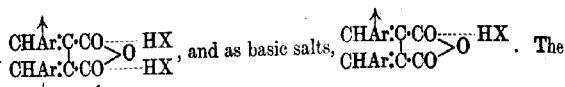

$\text{OH}\cdot\text{CPh}\cdot\text{C}(\text{CO}\cdot\text{CH}\cdot\text{CHPh})\cdot\text{CN}$ ,

lemon-yellow needles, m. p. 140°, and 4-cyano-1:3-di-phenyl-5-styrylpyrazole, colourless needles, m. p. 205° (decomp.).  $\beta$ -Cinnamoylaminocinnamionitrile,  $\text{CHPh}\cdot\text{CH}\cdot\text{CO}\cdot\text{NH}\cdot\text{CPh}\cdot\text{CH}\cdot\text{CN}$ , prepared

from the nitrile, cinnamic ester, and potassium ethoxide, crystallises in long, colourless needles or leaflets, m. p. 134—135°.

*Ethyl β-amino-α-phenoxyacetylcrotonate*,  
 $\text{NH}_2\cdot\text{CMe}\cdot\text{C}(\text{CO}\cdot\text{CH}_2\cdot\text{OPh})\cdot\text{CO}_2\text{Et}$ ,  
 m. p. 159°, is prepared by the action of ethyl β-aminocrotonate or phenoxyacetyl chloride and pyridine in the presence of ether. It is converted by the successive action of phenylhydrazine and alcoholic potassium hydroxide solution into 1-phenyl-3-phenoxy-methyl-5-methylpyrazole-4-carboxylic acid,  $\text{N}\begin{smallmatrix} \text{C}(\text{CH}_2\cdot\text{OPh}) \\ \text{NPh}-\text{CMe} \end{smallmatrix} \text{C}\cdot\text{CO}_2\text{H}$ , brown needles, m. p. 178°. *Ethyl β-phenoxyacetylaminocrotonate*,  $\text{OPh}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CO}_2\text{Et}$ , prepared by the ester method, crystallises in colourless needles, m. p. 88°. H. W.

**Halochromism of the Fulgides.** HANS STOBBE and RICHARD DIETZEL (*Ber.*, 1922, 55, [B], 3567—3580).—The absorption spectra of diphenylfulgide,  $\text{CHPh}\cdot\text{C}\cdot\text{CO}>\text{O}$ , and the corresponding tri- and tetra-phenyl compounds have been investigated. The substances dissolve in indifferent media such as light petroleum, alcohol, and chloroform, yielding solutions of their own colour in the solid state, whereas in strongly acidic liquids such as mono-, di-, and tri-chloroacetic acids they give solutions of a much darker colour. The isolation of the fulgides from these solutions in the form of their solid molecular compounds has not been accomplished, since they dissociate into their components in the presence of water, even when a large excess of acid is used. The investigation has therefore been confined to their solutions in chloroform and the three chloroacetic acids. The absorption of light is dependent on the strength of the acid; in the weakest of these, the limit of absorption approximates to that observed in chloroform solution. It therefore appears that, even in the presence of an excess of the acid, the fulgide is present partly as the monochloroacetate and partly as fulgide, and that this equilibrium is most markedly displaced in favour of the salt in the trichloroacetic acid solution. The constitution of the fulgide has a regular effect on the absorption of light. The ultra-violet spectra have also been examined. The absorption of solutions of the fulgides in chloroform are characterised by an ultra-violet band in the region of short wave-length and a "colour band" in the visible region. Increase in the number of the phenyl groups has no effect on the former, but causes an increased intensity in the latter and also a considerable displacement towards the red end. In the three chloroacetic acid solutions, the absorption is similar, but differs from that observed in chloroform. In place of the two bands of the latter, the ultra-violet band in the chloroacetic acid solutions disappears and is replaced by a narrow colour band which is very strongly displaced towards the red end. This displacement of the band is characteristic of the transition from a saturated to an unsaturated compound. It appears, therefore, that (in accordance with Pfeiffer's method of formulation) the fulgides function as normal salts,

formulae, however, are to be regarded only as structural approximations, since they do not take into account the established influence of the number of aryl radicles on the strength of the halochromism.

The colour of the arylfulgides is attributable to the ortho-quinonoid tetrahydrofuran nucleus,  $\begin{array}{c} >\text{C}:\text{C}=\text{CO} \\ >\text{C}:\text{C}=\text{CO} \end{array} >\text{O}$ , and to the

number and nature of the aryl substituents. The effect of the opening of the ring or alteration of its unsaturated character has been examined in the cases of diphenylfulgenic acid,  $\text{CO}_2\text{H}:\text{C}(\text{CHPh})\text{C}(\text{CHPh})\text{CO}_2\text{H}$ , triphenylfulgenic acid, and tetrahydrodiphenylfulgide (dibenzylsuccinic anhydride). The absorption curves of the fulgenic acids in chloroform are precisely similar to those in the chloroacetic acids, so that their molecular condition in the solutions must be almost the same. The halochromism which is so strongly marked with the fulgides has practically disappeared after the opening of the ring and loss of the quinonoid nucleus. A comparison of the absorption curve of tetrahydrodiphenylfulgide with that of diphenylfulgide shows that the former is much more transparent, and also that the narrow ultra-violet band of the latter persists after hydrogenation. On the other hand, the absorption curves of tetrahydrodiphenylfulgide in alcohol and trichloroacetic acid are very similar. In this case, as with the fulgenic acids, halochromism is scarcely perceptible; the carbonyl groups are not in themselves capable of uniting with chloroacetic acid. For this purpose, the ethylenic linkings of the non-hydrogenated fulgide are indispensable; they strengthen the unsaturated nature of the carbon atom, and thus indirectly cause a deepening of the colour.

H. W.

**Resorcinolphenylsuccinein.** ARTHUR LAPWORTH and JOHN ALEXANDER McRAE (T., 1922, 121, 2722—2724.)

**A Condensation of Dehydrodeoxycholic Acid.** TOMIHIDE SHIMIZU (Z. physiol. Chem., 1922, 123, 159—163).—Dehydrodeoxycholic acid on treatment with hydrogen chloride in alcoholic solution not only is esterified, but also an aldol condensation takes place between a keto-group of one molecule and a methylene group of another, and in addition the hydroxyl group formed in this process is replaced by chlorine, a compound,  $\text{C}_{32}\text{H}_{70}\text{O}_7\text{Cl}$ , m. p.  $204^\circ$ , being formed. On treatment with sodium ethoxide, this compound is hydrolysed and also loses hydrogen chloride, to yield an unsaturated dibasic acid,  $\text{C}_{48}\text{H}_{70}\text{O}_7$ , six-sided prisms, m. p.  $276^\circ$ . In addition to the above-mentioned condensation product, the simple ethyl ester, lustrous leaflets, m. p.  $108^\circ$ , can also be isolated, and if methyl alcohol is used instead of ethyl alcohol, no condensation takes place, the sole product being methyl dehydrodeoxycholate, fine needles aggregating into leaflets, m. p.  $130^\circ$ .

W. O. K.

**The Bile Acids. XV.  $\psi$ -Choloidanic Acid.** HEINRICH WIELAND (*Z. physiol. Chem.*, 1922, **123**, 237—245).— $\psi$ -Choloidanic acid formed, along with choloidanic acid, in the oxidation of deoxybilanic acid has the formula  $C_{24}H_{34}O_{10}$ . It forms a neutral tetramethyl ester,  $C_{28}H_{42}O_{10}$ , a dimethyl ester,  $C_{26}H_{38}O_{10}$ , long needles, m. p. 268°, and a barium salt,  $C_{28}H_{36}O_{10}Ba$ , glistening needles. When heated, it loses carbon dioxide and water, to form *pyro- $\psi$ -choloidanic acid*,  $C_{22}H_{30}O_6$ , lustrous leaflets, m. p. 246° (hydrate,  $C_{22}H_{30}O_6 \cdot H_2O$ , glistening needles, m. p. 115—116°). The dimethyl ester of  $\psi$ -choloidanic acid yields, when heated, the neutral ester of a monobasic acid,  $C_{23}H_{29}O_5 \cdot OMe$ , m. p. 192°. W. O. K.

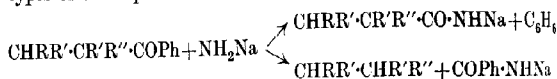

**The Bile Acids. XIV. Cilianic Acid, Ciloidanic Acid, and Biloidanic Acid.** HEINRICH WIELAND and ORTO SCHLICH-TUNG (*Z. physiol. Chem.*, 1922, **132**, 213—236; cf. A., 1922, i, 838).—Ciloidanic acid,  $C_{29}H_{34}O_{13}$ , may be oxidised by nitric acid, *d* 1.52, to biloidanic acid,  $C_{22}H_{32}O_{12}$ . The formula given previously for this acid,  $C_{23}H_{34}O_{12}$ , is not correct, and it is found that it is identical with norsolanellanic acid. When heated with sulphuric acid, ciloidanic acid loses carbon dioxide and carbon monoxide, to yield a *keto-tetracarboxylic acid*,  $C_{22}H_{32}O_9$ , needles, m. p. 238°,  $[\alpha]_D^{25} + 73.5^\circ$ . This keto-carboxylic acid on oxidation by nitric acid (*d* 1.4) yields biloidanic acid in a very pure form, and by this means the new formula has been established. Biloidanic acid when heated in a vacuum loses water and carbon dioxide to yield *pyrobiloidanic acid*,  $C_{21}H_{28}O_9$ , fine, microscopic prisms, m. p. 193—195°. If this acid is heated with alkali, an internal lactone ring is hydrolysed, and an acid,  $C_{21}H_{30}O_9 \cdot H_2O$ , is formed. The constitution of the bile acids is discussed in the light of these results, and modifications of the earlier formulæ are suggested. W. O. K.

**The Acidity of Gallaldehyde.** M. NIERENSTEIN (*Ber.*, 1922, **55**, [B], 3581).—The presumed great acidity of gallaldehyde has been regarded by Rosenmund and Zetzsche (A., 1918, i, 301) as indirect evidence against Nierenstein's observation (A., 1909, i, 402) that gallaldehyde is formed by the hydrolysis of gallotannin. The recognition that the aldehyde is not so acidic as was supposed (Rosenmund and Pfannbuch, A., 1922, i, 1030) invalidates this argument. H. W.

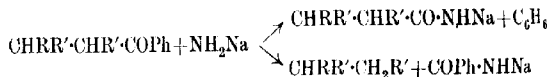

**The Condensation of *o*-Halogenoketones with Aldehydes.** SVEN BODFORSS (*Ber.*, 1922, **55**, [B], 3581).—A claim for priority against Bauer and Werner (A., 1922, i, 1034; cf. Bodfors, A., 1917, i, 223; 1919, i, 211). H. W.

**Some  $\alpha\alpha\beta\beta$ -Tetra-substituted Propiophenones and the Products they yield on Decomposition with Sodamide.** GEORGES ALBESCO (*Ann. Chim.*, 1922, **18**, 216—262; cf. Haller and Bauer, A., 1909, i, 108, 654; 1910, i, 300; Dumesnil, A., 1911, i, 718).—A study of the action of organo-magnesium compounds on phenyl styryl ketone and phenyl methylphenedioxystyryl ketone with formation of  $\beta\beta$ -substituted acetophenones and subsequent substitution

in the  $\alpha$ -position with methyl or ethyl groups, resulted in the preparation of the following compounds. *Phenyl  $\alpha$ -ethylstyryl ketone*, a viscous liquid, b. p.  $208^{\circ}/14$  mm.  *$\beta$ -Phenyl- $\beta$ -p-tolyl-propiophenone*, colourless crystals, m. p.  $96^{\circ}$ , b. p.  $254^{\circ}/12-13$  mm.  *$\beta$ -Methylenedioxyphenyl- $\beta$ -methylpropiophenone*, prisms, m. p.  $73^{\circ}$ .  *$\beta$ -Methylenedioxyphenyl- $\beta$ -ethylpropiophenone*, colourless prisms, m. p.  $58^{\circ}$ , b. p.  $233^{\circ}/11$  mm.  *$\beta$ -Phenyl- $\beta$ -methylenedioxyphenylpropiophenone*, crystals, m. p.  $97^{\circ}$ , b. p.  $280^{\circ}/14$  mm.  *$\beta\beta$ -Diphenyl- $\alpha\alpha$ -dimethylpropiophenone*, m. p.  $90^{\circ}$ .  *$\beta\beta$ -Diphenyl- $\alpha$ -ethylpropiophenone*, m. p.  $118^{\circ}$ .  *$\beta$ -Phenyl- $\alpha$ -methyl- $\beta$ -ethylpropiophenone*, crystals, m. p.  $54-55^{\circ}$ .  *$\beta$ -Phenyl- $\alpha\alpha$ -dimethyl- $\beta$ -ethylpropiophenone*, mobile liquid, b. p.  $195^{\circ}$ ;  *$\beta$ -phenyl- $\alpha\alpha$ -triethylpropiophenone*, mobile liquid, b. p.  $195^{\circ}$ , 760 mm.;  *$\beta$ -phenyl- $\beta$ -p-tolyl- $\alpha$ -methylpropiophenone*, colourless crystals, m. p.  $116^{\circ}$ ;  *$\beta$ -phenyl- $\beta$ -p-tolyl- $\alpha$ -ethylpropiophenone*, colourless crystals, m. p.  $131^{\circ}$ , b. p.  $252^{\circ}/12$  mm.  *$\beta$ -Phenyl- $\beta$ -methoxyphenyl- $\alpha$ -methylpropiophenone*, m. p.  $128^{\circ}$ .  *$\beta$ -Methylenedioxyphenyl- $\alpha\beta$ -dimethylpropiophenone*, m. p.  $70^{\circ}$ .  *$\beta$ -Methylenedioxyphenyl- $\alpha\alpha\beta$ -trimethylpropiophenone*, colourless, mobile liquid, b. p.  $230^{\circ}$ .  *$\beta$ -Methylenedioxyphenyl- $\alpha$ -methyl- $\beta$ -ethylpropiophenone*, an oil, b. p.  $236^{\circ}/15$  mm.  *$\beta$ -Methylenedioxyphenyl- $\alpha\alpha$ -dimethyl- $\beta$ -ethylpropiophenone*, an oil, b. p.  $235^{\circ}/11$  mm.;  *$\beta$ -methylenedioxyphenyl- $\alpha\beta$ -diethylpropiophenone*, an oil, b. p.  $234-235^{\circ}/13-14$  mm.  *$\beta$ -Phenyl- $\beta$ -methylenedioxyphenyl- $\alpha$ -methylpropiophenone*, needles, m. p.  $128^{\circ}$ . In those cases in which both  $\beta$ -substituents are of aromatic type, the second  $\alpha$ -substitution takes place with difficulty. The action of sodamide on the tetra-substituted derivatives results in fission of the ketone molecule at two different points, the two types of decomposition occurring to the same extent:

The reaction affords a ready means of preparing tetra-substituted propionic acids. The action of sodamide under the influence of heat on the ketones which are mono-substituted in the  $\alpha$ -position results in formation of two products:

Among the substances obtained by the action of sodamide are the following.  *$\beta\beta$ -Diphenyl- $\alpha\alpha$ -dimethylpropionamide*, white crystals, m. p.  $120^{\circ}$ .  *$\alpha\alpha$ -Diphenyl- $\beta$ -methylpropane*, mobile, colourless liquid, b. p.  $145^{\circ}/13$  mm.  *$\gamma$ -Phenyl- $\beta$ -methylpentane*, mobile, colourless liquid, b. p.  $200^{\circ}$ .  *$\beta$ -Phenyl- $\alpha\alpha$ -dimethylvaleramide*, viscous liquid, b. p.  $180^{\circ}/11$  mm.  *$\delta$ -Phenyl- $\gamma$ -ethylhexane*, mobile, colourless liquid, b. p.  $205^{\circ}$ .  *$\beta$ -Phenyl- $\alpha\alpha$ -dimethylvaleric acid*, crystals, m. p.  $82^{\circ}$ .  *$\beta$ -Phenyl- $\alpha\alpha$ -diethylvaleric acid*, m. p.  $68-69^{\circ}$ .  *$\beta\beta$ -Diphenyl- $\alpha$ -ethylpropionamide* [ *$\alpha$ -benzhydrylbutyramide*], colourless crystals, m. p.  $151^{\circ}$ .

H. J. E.

**The Synthesis of  $\beta$ -Keto-bases from Fatty-aromatic Ketones, Formaldehyde, and Secondary Amines.** C. MANNICH and D. LAMMERING (*Ber.*, 1922, 55, [B], 3510—3526).— $\beta$ -Ketonic bases may be prepared from the salts of secondary amines, formaldehyde, and fatty-aromatic ketones in accordance with the equation:

Reaction is usually effected by boiling molar quantities of the salt and concentrated formaldehyde solution with the fatty-aromatic ketone. Frequently, it is advantageous to work in the absence of moisture, for example, by heating the amine salt and ketone with paraformaldehyde in the presence of alcohol, in which case an excess of aldehyde must be used. The synthesis is capable of considerable variation. The ketonic component may be acetophenone, methoxyacetophenone, acetoveratrone, propiophenone, deoxybenzoin, or  $\beta$ -acetyltetrahydronaphthalene, but apparently not *p*-acetylamidoacetophenone, whereas the basic component may be dimethylamine, diethylamine, piperidine, tetrahydroisoquinoline, or piperazine, but not tetrahydroquinoline. The keto-bases and their hydrochlorides are, in general, fairly stable, but are more or less rapidly decomposed at their boiling points into a tertiary amine and an unsaturated ketone thus, for example,

The free bases are sometimes solid, and are then purifiable by crystallisation, and sometimes liquid; in the latter case, they cannot be purified, since they decompose on distillation under diminished pressure. In many cases, they have been further characterised by the formation of oximes, but the process does not occur smoothly when the dimethylamino-group is present in the molecule. The  $\beta$ -keto-bases are most conveniently reduced to the corresponding secondary alcohols by hydrogen in the presence of palladium, but zinc dust and hydriodic acid may also be used. Sodium and alcohol are unsuitable, since loss of the amine residue is caused thereby; aluminium amalgam in the presence of moist ether reduces the ketones to pinacone-like substances. The alcoholic bases, in contrast to the ketonic compounds, are quite stable, and can be distilled under diminished pressure without decomposition.

The synthesis just described allows the ready preparation of substances which contain nitrogen in the  $\gamma$ -position to the benzene nucleus. In contrast to the behaviour of the similar substances containing the nitrogen in the  $\beta$ -position, the compounds,

$OH \cdot C_6H_4 \cdot CO \cdot CH_2 \cdot CH_2 \cdot NMe_2$ , and  $C_6H_3(OH)_2 \cdot CO \cdot CH_2 \cdot CH_2 \cdot NMe_2$ , do not cause any rise in the blood pressure. Anaesthetising properties are shown by the compounds,  $CH_2Bz \cdot CH_2 \cdot C_5NH_{10}$ .

$CH_2Bz \cdot CH_2 \cdot N < \begin{array}{c} CH_2 \\ CH_2 \cdot CH_2 \end{array} > C_6H_4$ , and  $CHPhBz \cdot CH_2 \cdot C_5NH_{10}$  (all of which contain the benzoyl group, but not in the form of ester), and by the substances  $OMe \cdot C_6H_4 \cdot CO \cdot CH_2 \cdot CH_2 \cdot C_5NH_{10}$ .

$C_{10}H_{11}\cdot CO\cdot CH_2\cdot CH_2\cdot NMe_2$ ,  $C_{10}H_{11}\cdot CO\cdot CH_2\cdot CH_2\cdot C_5NH_{10}$ , and  $OMe\cdot C_6H_4\cdot CO\cdot CHMe\cdot CH_2\cdot C_5NH_{10}$ . The  $\beta$ -amino-alcohols are not anaesthetics in themselves, but exhibit extremely active properties in the form of their benzoates, being in some cases markedly more potent than cocaine. Unfortunately, they have also an irritant action.

The following individual substances are described.  $\beta$ -Piperidinoethyl phenyl ketone,  $C_5NH_{10}\cdot CH_2\cdot CH_2\cdot C_6H_5$ , a colourless, odourless liquid (hydrochloride, m. p. 192–193°, picrate, needles, m. p. 180.5°, and oxime, needles, m. p. 143°). 1:6-Dipiperidino-3:4-diphenylhexane-3:4-diol,

$C_5NH_{10}\cdot CH_2\cdot CH_2\cdot C_6H_4(OH)\cdot C_6H_4(OH)\cdot CH_2\cdot CH_2\cdot C_5NH_{10}$ , ( $\alpha$ -form), m. p. 238° (decomp.) [hydrochloride, decomp. about 270°], ( $\beta$ -form), large plates, m. p. 115°.  $\beta$ -Piperidinoethylphenylcarbinol,  $OH\cdot CHPh\cdot CH_2\cdot CH_2\cdot C_5NH_{10}$ , leaflets, m. p. 68–69° (hydrochloride, m. p. 138°; picrate, needles, m. p. 103°; benzoate, flattened needles, m. p. 170°; p-nitrobenzoate, brown needles, m. p. 104°; p-aminobenzoate, m. p. 118°).  $\beta$ -Tetrahydroisoquinolinoethyl phenyl ketone,  $C_6H_4\cdot CH_2\cdot CH_2\cdot N\langle\begin{smallmatrix} CH_2 \\ CH_2\cdot CH_2 \end{smallmatrix}\rangle\cdot C_6H_5$ , a viscous liquid

which solidifies in a freezing mixture, and its hydrochloride, m. p. 188°. 1:4-Di- $\beta$ -benzoyl ethylpiperazine, crystalline granules, m. p. 141° (hydrochloride, decomp. 190°; picrate, needles, decomp. above 190°; diaxime, m. p. 245°). p-Methoxyphenyl  $\beta$ -dimethylaminoethyl ketone hydrochloride,  $C_6H_4(OMe)\cdot CO\cdot CH_2\cdot CH_2\cdot NMe_2\cdot HCl$ , needles, m. p. 181° (corresponding picrate, m. p. 145°); the hydrochloride is decomposed at 180°/20 mm., into dimethylamine hydrochloride and p-anisyl vinyl ketone, b. p. 138–142°/20 mm., m. p. 19° (corresponding dibromide, prisms, m. p. 71°). ? 1-Phenyl-3-p-anisylpyrazoline,

$\begin{smallmatrix} NPh \\ | \\ CH_2\cdot CH_2 \end{smallmatrix} \rangle C\cdot C_6H_4\cdot OMe$ , m. p. 105° (from the vinyl ketone and phenylhydrazine). Anisyl ethyl ketone semicarbazone, m. p. 176°. p-Hydroxyphenyl  $\beta$ -dimethylaminoethyl ketone hydriodide, pale yellow leaflets, m. p. 205° (from the methoxy compound and hydriodic acid), and the corresponding hydrochloride, pale yellow leaflets, m. p. 189°. p-Anisyl- $\beta$ -dimethylaminoethylcarbinol, b. p. 146–148°/30 mm., m. p. 53° (hydrochloride, needles, m. p. 203–204°; hydrochloride of the corresponding benzoate, m. p. 174°).  $\beta$ -Piperidinoethyl p-anisyl ketone, a liquid which solidifies in a freezing mixture (hydrochloride, needles, m. p. 216°; picrate, short needles, m. p. 165°; oxime, needles, m. p. 136°). 1:4-Di-p-anisylethylpiperazine,  $C_4N_2H_8(CH_2\cdot CH_2\cdot CO\cdot C_6H_4\cdot OMe)_2$ , pale yellow leaflets, m. p. 173° after darkening at 171° (the hydrochloride darkens without melting above 150°).  $\beta$ -Piperidinoisopropyl p-anisyl ketone,  $OMe\cdot C_6H_4\cdot CO\cdot CHMe\cdot CH_2\cdot C_5NH_{10}$ , a liquid prepared from piperidine, p-anisyl ethyl ketone, and paraformaldehyde (hydrochloride, leaflets, m. p. 178°; oxime, m. p. 94°). 3:4-Dimethoxyphenyl- $\beta$ -dimethylaminoethyl ketone,

$C_6H_3(OMe)_2\cdot CO\cdot CH_2\cdot CH_2\cdot NMe_2$ , a viscous liquid (hydrochloride, needles, m. p. 181–182°; picrate, needles, m. p. 157°). 3:4-Dihydroxyphenyl  $\beta$ -dimethylaminoethyl ketone (from the hydrochloride of the corresponding methoxy-

compound and hydriodic acid), isolated as the *hydriodide*, pale yellow crystals, m. p. 196°, and *hydrochloride*, needles, m. p. 179°.

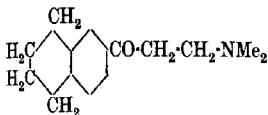

3:4-Dimethoxy-γ-dimethylaminopropylbenzene,

a colourless liquid, b. p. 161–164°/30 mm., prepared unexpectedly by the reduction of the corresponding ketone by hydrogen in the presence of palladised animal charcoal (*hydrochloride*, needles, m. p. 195°). β-Piperidinoethyl-3:4-dimethoxyphenyl ketone, m. p. 113° (*hydrochloride*, small prisms, m. p. 183°; *picrate*, m. p. 180°; *oxime*, needles, m. p. 168°). 1:4-Di-β-veratroylethylpiperazine,

yellow needles, m. p. 168° (*hydrochloride*, short needles which decompose without melting above 150°). Veratryl β-diethylaminoethyl ketone,  $\text{C}_6\text{H}_3(\text{OMe})_2\cdot\text{CO}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{NEt}_2$ , a colourless liquid (*hydrochloride*, needles, m. p. 140–141°; *picrate*, m. p. 136°; *oxime*, large needles, m. p. 104°). α-Piperidino-β-γ-diphenylpropane-γ-one,  $\text{C}_6\text{NH}_{10}\cdot\text{CH}_2\cdot\text{CHPh}\cdot\text{COPh}$ , (from deoxybenzoin, piperidine *hydrochloride*, and paraformaldehyde), a crystalline powder, m. p. 91° (the *hydrochloride* is very hygroscopic; *nitrate*, short needles, m. p. 117°). β-Tetrahydronaphthyl β-dimethylaminoethyl ketone (an-  
 nexed formula), a liquid (*hydrochloride*, needles, m. p. 170°; *picrate*,  
 needles, m. p. 156°). β-ar-

viscous liquid [*hydrochloride*, m. p. (anhydrous) 170°, (+aq.) 85°; *nitrate*, needles, m. p. 134–135°; *oxime hydrochloride*, silky needles, m. p. 211°].

**The Influence of Substitution in the Components of Binary Solution Equilibria. XXXVII. The Systems of p-Benzoquinone with Phenols, Amines, and Hydrocarbons.** ROBERT KREMANN, SEPP SUTTER, FRANZ SITTE, HUBERT STRZELBA, and ALADAR DOBOTZKY (*Monatsh.*, 1922, 43, 269–313).—A systematic investigation has been made of the additive compounds of quinhydrone character formed by p-benzoquinone with a number of aromatic hydroxy-compounds, amines, and hydrocarbons. The method of attack adopted was through the determination of the condition-diagram of the binary system formed between p-benzoquinone and the substance under examination. Early experiments on these lines failed to give satisfactory results for two reasons. First, it was not realised that the additive compounds are not formed instantaneously when the two components are fused together, but frequently some considerable time at a higher temperature is needed to establish equilibrium. This phenomenon has not previously been recorded in the case of additive compounds between organic substances. Secondly, at the high temperatures at which fusion occurred, secondary reactions frequently started to some extent, rendering the observations worthless. The latter difficulty

was overcome by the addition to the binary system of a constant quantity of a third inactive substance, for which nitrobenzene was chosen. The ternary system could be treated as a quasi-binary system, and the nitrobenzene, by lowering the temperatures at which fusion and primary crystallisation took place, lessened the chance of the occurrence of secondary reactions between the *p*-benzoquinone and the other component. The existence of the following compounds between quinone and aromatic hydroxy-compounds was established from the occurrence of maxima in the *T-x* curves of the equilibrium diagrams: with phenol,  $C_6H_4O_2 \cdot 2PhOH$ ; with quinol,  $C_6H_4O_2 \cdot C_6H_4(OH)_2$ ; with pyrocatechol,  $2C_6H_4O_2 \cdot C_6H_4(OH)_2$ ; with resorcinol,  $2C_6H_4O_2 \cdot C_6H_4(OH)_2$ ; with pyrogallol,  $3C_6H_4O_2 \cdot C_6H_4(OH)_3$ .

These compounds can be explained on the assumption that combination takes place between the hydroxy-group and one of the two oxygen fields of force of the benzoquinone. In the cases of pyrocatechol, resorcinol, and pyrogallol, steric hindrance allows only one field of force of each benzoquinone molecule to come into play. The two naphthols both form, at first, equimolecular compounds,  $C_6H_4O_2 \cdot C_{10}H_7OH$ , but when the mixtures are heated for some time to a higher temperature, compounds of higher melting point containing two mols. of benzoquinone to one of naphthol are formed. This combination with a second molecule of benzoquinone must be attributed to the benzenoid fields of force. Of the three nitrophenols, 1:2:4-dinitrophenol, and picric acid, only *p*-nitrophenol forms a compound with quinone, the equimolecular compound,  $C_6H_4O_2 \cdot OH \cdot C_6H_4NO_2$ . Triphenylcarbinol forms no compound. Only three systems with amines were studied successfully. *p*-Toluidine, when carefully melted with *p*-benzoquinone, forms a simple mixture giving a eutectic; after warming the mixture some time, however, an equimolecular compound,

is formed. Since aniline is known to form the compound

it is evident that the *p*-methyl group has a similar effect on the combining power of aniline to the *p*-nitro-group on that of phenol.  $\alpha$ -Naphthylamine forms an equimolecular compound with *p*-benzoquinone, whilst  $\beta$ -naphthylamine, which at first forms no compound, when warmed for some time forms two compounds,  $C_6H_4O_2 \cdot C_{10}H_7NH_2$  and  $2C_6H_4O_2 \cdot C_{10}H_7NH_2$ . No compounds were detected between *p*-benzoquinone and any of the hydrocarbons triphenylmethane, naphthalene, acenaphthene, phenanthrene, fluorene, or with diphenylamine or carbazole, but anthracene forms an equimolecular compound.

E. H. B.

**The Catalytic Action of Mercury in the Sulphonation of Anthraquinone.** G. W. CLOUGH (*J. Soc. Dyers and Col.*, 1921, 38, 299–300).—After several attempts, the author has failed to confirm the statement of Martinef and Roux (*A.*, 1921, i, 732) that in the sulphonation of anthraquinone by means of fuming sulphuric acid in the presence of mercury as a catalyst, the  $\alpha$ -sulphonic acid

is always formed first and that this simultaneously changes into the  $\beta$ -isomeride.

A. J. H.

**Bromonitrocamphane.** P. M. GINNINGS and W. A. NOYES (*J. Amer. Chem. Soc.*, 1922, **44**, 2567—2573; cf. Forster, T., 1897, **71**, 199, 1030; 1899, **75**, 1141; 1900, **77**, 251; 1901, **79**, 108, 264, 644, 653, 987, 1003; 1902, **81**, 865; 1903, **83**, 78).—Further evidence is given in support of Forster's work on this subject, and definite proof of the structure of bromonitrocamphane anhydride is advanced.

On oxidation with nitric acid, bromonitrocamphane breaks down successively into camphor, camphoric acid, and camphoronic acid. The authors found no evidence of the formation of a hydrate of bromonitrocamphane, as suggested by Forster, during the action of potassium hypobromite on camphoroxime, but did find that a certain amount of hydroxynitrosocamphane was formed. The course of the action of the hypobromite is bromination of the camphoroxime and then oxidation to bromonitrocamphane. The anhydride of the last-named compound is best prepared by dissolving it in light petroleum of low boiling point and adding this to a mixture of concentrated sulphuric acid and light petroleum kept at  $-10^{\circ}$ . The anhydride reacts with Grignard's reagent to give *methylobromonitrocamphane anhydride*, m. p. 117—118°, which yields a *benzoyl* derivative, m. p. 113—114°, and is decomposed by alcoholic sodium hydroxide to give acetylcamphenylcarboxylic acid.

W. G.

**Preparation of Polycyclic Hydrocarbons of the Terpene Series.** CHEMISCHE FABRIK AUF ACTIEN (FORM. E. SCHERING) (D.R.P. 353933; from *Chem. Zentr.*, 1922, iv, 499).—Hydrazones of terpene ketones are heated with mercuric oxide in indifferent solvents; or the double salts of the hydrazones with mercuric chloride in the presence of an equivalent amount of alkali are heated in indifferent solvents. Slightly soluble basic mercury compounds are thereby formed which decompose on heating, as, for example,  $C_{10}H_{16} \cdot N \cdot NH \cdot Hg \cdot OH = C_{10}H_{16} + N_2 + Hg + H_2O$ .

*Tricyclene*, b. p. 153.5°, m. p. 63.5°, is formed from camphorhydrazone and mercuric oxide in alcohol after eight hours' heating. *d-Cyclofenchene*, from *d-fenchonehydrazone*, has b. p. 142.5—143.5°,  $d_D^{20}$  0.8588,  $n_D^{20}$  1.45134,  $[\alpha]_D^{20} +0.45^{\circ}$ . *apocyclene*, from camphenylhydrazone, has b. p. 138—139°, b. p. 120.5°/17 mm., m. p. 40.1°,  $d_D^{20}$  0.8694,  $n_D^{20}$  1.44914.

G. W. R.

**Oxidation of Sabinene with Chromyl Chloride.** GEORGE GERALD HENDERSON, JOHN MCGREGOR ROBERTSON, and DAVID CHRISTIE BROWN (T., 1922, **121**, 2717—2721).

**Constituents of some Indian Essential Oils.** JOHN LIONEL SIMONSEN and MADYAB GOPAL RAU (*Indian Forest Rec.*, 1922, **9**, 111—146).—I. The oleo-resin of *Pinus khasya* yields 57% of rosin. The turpentine essential oil has  $d_{20}^{20}$  0.8633,  $n_D^{20}$  1.4675, and  $[\alpha]_D^{20} +32.83^{\circ}$ . On distillation, it gives 70.6%, boiling at 153—155°, consisting of *d- $\alpha$ -pinene*, 11.7% at 159—169°, consisting of a

mixture of  $\alpha$ - and  $\beta$ -pinenes, and the higher fractions contain a terpene identical with *d*-longifolene.

II. The oleo-resin of *Pinus excelsa* yields about 68% of rosin. By fractionation of the oil, 87.9% of very pure *d*- $\alpha$ -pinene was obtained, together with *d*-terpineol, a bicyclic sesquiterpene, and a small quantity of a saturated hydrocarbon,  $C_{11}H_{24}$ , which appeared to be *n*-undecane. The turpentine itself had the constants  $d_{20}^{20}$  0.857,  $n_D^{20}$  1.4627, and  $[\alpha]_D^{20}$  +40.42°.

III. The essential oil from *Cedrus deodara*, Loudon, has already been examined by Roberts (T., 1916, 109, 791) and his results are in the main confirmed. The ketone present to the extent of 8–10% was definitely identified as 4-methyl- $\Delta^3$ -cyclohexenyl methyl ketone. The sesquiterpene (40%) was isolated as a colourless oil, b. p. 152–154°/40 mm.,  $d_{20}^{20}$  0.9195,  $n_D^{20}$  1.5040, and  $[\alpha]_D^{20}$  +13.86°. No crystalline derivatives could be obtained, and the substance was not identified. A sesquiterpene alcohol, b. p. 202–204°/55 mm., was also isolated in about 40% yield. It formed a viscid yellow oil,  $d_{20}^{20}$  0.9578,  $n_D^{20}$  1.515,  $[\alpha]_D^{20}$  +38.41. It gave no crystalline derivatives and could not be further characterised. No phenol, heptioic, or stearic acids were found, but the presence of esters of butyric, hexoic, and an unidentified crystalline acid, m. p. 110°, was confirmed.

IV. The essential oil from the grass *Andropogon Jwarancusa*, Jones (cf. T., 1922, 121, 2295), collected in Sind has a lower rotation ( $[\alpha]_D^{20}$  +42.8°), a higher density (0.9228), and a higher refraction ( $n_D^{20}$  1.4858) than that from grass of reputedly the same species grown in the Hazara district (cf. T., 1921, 119, 1645). It contains only 44% of piperitone, together with 24% of the terpene *d*- $\Delta^4$ -carene, identical with that in the Hazara oil, about 28% of a sesquiterpene alcohol, b. p. 176–177°/31 mm., 2% of an unidentified alcohol having an odour of roses, and small quantities of either free or combined palmitic, decoic, and octoic acids. The oil as a whole closely resembles that from *Cymbopogon Sennaarensis* described by Roberts (T., 1915, 107, 1465) rather than the Hazara oil.

V. The essential oil from the seeds of *Xanthoxylum alatum*, Roxb., contains more than 85% of *l*- $\alpha$ -phellandrene, together with a small proportion of linalool, and an unidentified sesquiterpene.

VI. The essential oil from the seeds of *Xanthoxylum acanthopodium*, DC. (yield 1.2%), had the following constants:  $d_{20}^{20}$  0.8837,  $n_D^{20}$  1.4746,  $[\alpha]_D^{20}$  +6.54°, saponification value 60.79, ditto after acetylation 242.5. The chief constituents are dipentene, methyl cinnamate, and more than 50% of linalool. In addition, *l*- $\alpha$ -phellandrene, a small quantity of an aldehyde or ketone, and a mixture of fatty acids consisting probably of hexoic, octoic, and heptioic acids were found.

VII. The essential oil from the seeds of *Xanthoxylum Budrunga*, Wall., is apparently identical with that examined by Semler (A., 1911, i, 1002) and stated by him to have been obtained from *X. alatum*. The terpene named by him xanthoxylene is definitely shown to be *L*-sabinene, as it gave sabinic acid, m. p. 55–57°, on oxidation, 1:4-terpin, on treatment with dilute sulphuric acid,

and terpinene dihydrochloride with hydrogen chloride in acetic acid solution. In addition to this hydrocarbon, terpinene was found in small quantities in the oil, together with an unidentified alcohol. No dimethoxyphloracetophenone could be found in the sample of oil examined.

G. F. M.

**Essential Oils.** SCHIMMEL & Co. (*Rep. Schimmel & Co.*, 1922, 5—166; from *Chem. Zentr.*, 1922, iv, 763—764).—Descriptions are given of a number of essential oils, many of which have already appeared. Essential oil from *Abies pindrow* (Indian silver fir) has  $d^{15}_4$  0.8647,  $[\alpha]_D -10^\circ 59'$ ,  $n_D^{20}$  1.47328, acid number 0.3; ester number 6.5. Indian baldrian oil has  $d^{15}_4$  0.9361,  $[\alpha]_D -34^\circ 6'$ ,  $n_D^{20}$  1.48712, acid number 37.3, ester number 39.8, acetyl number 69.1. Essential oil from *Erigeron canadense* has  $d^{15}_4$  0.8720,  $[\alpha]_D +53^\circ 56'$ ,  $n_D^{20}$  1.49922, acid number 0.3, ester number 63.5, acetyl number 70.3. Pine needle oil from *Tsuga canadensis* has (Cable, *J. Amer. Pharm. Assoc.*, 1921, 10, 170)  $d^{20}_4$  0.9020—0.9234,  $[\alpha]_D^{20} -14.80^\circ$  to  $21.65^\circ$ ,  $n_D^{20}$  1.4691—1.4704, acid number 0.33—0.71, ester number 103.8—147.35, acetyl number 113.5—171.94. Essential oil from *Tsuga heterophylla* has  $d^{20}_{15}$  0.8444—0.8521,  $[\alpha]_D^{20} -6^\circ$  to  $-20^\circ$ ,  $n_D^{20}$  1.4790—1.4840, acid number 2.57—3.4, ester number 6.7—17.25, acetyl number 19.6—33.4. Spanish oil of thyme has  $d^{15}_4$  0.9297,  $[\alpha]_D +0^\circ 35'$ ; it contains 45% of thymol, also amyl alcohol, amylcarbinols,  $\Delta^8$ -hexenol, and a new terpene,  $C_{11}H_{18}$ , of carrot-like odour, b. p. 155—156°, with  $d^{15}_4$  0.8533—0.8537,  $[\alpha]_D +4^\circ 35'$  to  $4^\circ 50'$ ,  $n_D^{20}$  1.46201—1.46231. The latter compound gives a nitrosochloride which decomposes at about 85°, a nitropiperidine, m. p. 194—195°, and a nitrolamine, m. p. 105—108°. The oil also contains camphene,  $\alpha$ -pinene,  $p$ -cymol,  $\gamma$ -terpinene, linalool,  $l$ -borneol,  $\psi$ -terpineol, geraniol, and caryophyllene. Essential oil from *Cicuta virosa*, L., has  $d^{15}_4$  0.8909,  $[\alpha]_D +16^\circ 32'$ ,  $n_D^{20}$  1.4848, acid number 3.7, ester number 17.7.

G. W. R.

**Caoutchouc.** RUDOLF PUMMERER and PETER A. BURKARD (*Ber.*, 1922, 55, [B], 3458—3472).—Caoutchouc dissolved in hexahydrotoluene has been submitted to catalytic hydrogenation in the presence of spongy platinum. In order to obtain a highly depolymerised and therefore highly active material, very dilute solutions (0.2—0.6%) are employed. The reaction occurs at the atmospheric temperature, but is more conveniently studied at 70—80° with freshly purified caoutchouc and recently prepared catalyst. With more concentrated solution (even 1%) the hydrogenation is frequently incomplete, possibly owing to poisoning of the catalyst by adsorbed caoutchouc. The caoutchouc absorbs one molecular proportion of hydrogen for each isoprene residue,  $(C_5H_8)_x + xH_2 = (C_5H_{10})_x$ , and there is no tendency towards further union with hydrogen after this stage is reached. If the caoutchouc molecule contained the isoprene residues in an open chain, a greater absorption of hydrogen would be expected in accordance with the scheme  $(C_5H_8)_x + (x+1)H_2 = C_{5x}H_{10x+2}$ . The accuracy attained in the experiments permits the conclusion to be drawn that caoutchouc consists either of a ring system or of an unusually long chain of

isoprene residues ( $x > 20$ ). The isolation of the hydrocaoutchouc from the solutions is somewhat difficult, since the product in substance and in solution is readily dehydrogenated to caoutchouc (at any rate in the presence of unavoidable traces of platinum). Precipitation of the colloid by kaolin in the absence of air and subsequent removal of the solvent under diminished pressure in an atmosphere of hydrogen yields *hydrocaoutchouc* as a very pale yellow, elastic skin, which swells and ultimately dissolves in ether and closely resembles ordinary caoutchouc. It certainly retains the high molecular weight.

The autoxidation of hydrocaoutchouc has been quantitatively studied by removing the excess of hydrogen by evacuation from the apparatus in which the substance has been prepared and subsequently agitating the solution with oxygen (in the presence of the platinum). A volume of oxygen, equal to half that of the hydrogen previously used, is rapidly absorbed, after which the action proceeds much more slowly and at approximately the same rate as observed with a similar solution of caoutchouc in hexahydrotoluene. The product of the autoxidation, *isocaoutchouc* II, when freshly prepared, dissolves easily and rapidly in ether without protracted swelling phenomena. When treated with hydrogen and spongy platinum, it rapidly absorbs one molecular proportion of the gas for each isoprene residue, thus showing that bridged linkings are not present in the molecule. In its solubility, *isocaoutchouc* II appears to be more closely allied to Harries's  $\alpha$ - and  $\beta$ -*isocaoutchouc* than to caoutchouc.

The absorption of gaseous oxygen by a very dilute solution of caoutchouc in hexahydrotoluene appears to be finished at the atmospheric temperature when a molecular proportion of oxygen has been used for every two isoprene residues. It is immaterial whether the action takes place in the presence or absence of spongy platinum. The tardiness with which absorption by concentrated solutions of caoutchouc occurs is very manifest.

The action of perbenzoic acid on solutions of caoutchouc in chloroform at  $0^\circ$  gives a viscous *caoutchouc oxide*,  $(C_8H_8O)_2$ , which is insoluble in all media. Products richer in oxygen are obtained in the presence of moisture. Reaction with the theoretical quantity of perbenzoic acid is almost complete after one hour, so that caoutchouc behaves normally towards this reagent.

The viscosity of a solution of caoutchouc in benzene at  $25^\circ$  is not changed if the solution is heated to gentle ebullition during eight hours and subsequently cooled rapidly or slowly to  $25^\circ$ ; if therefore a polymerisation equilibrium exists in caoutchouc solutions, it must be very rapidly attained. The coagulation of caoutchouc in boiling benzene is not observed with 2% solutions, but occurs slowly with 4% solutions. It does not take place during ten hours at  $50^\circ$ . The phenomenon is reversible.

H. W.

**Centaurein ; a New Glucoside obtained from the Roots of *Centaurea Jacea*.** MARC BRIDEL and CAMILLE CHARAUX (*Compt. rend.*, 1922, 175, 833—835).—*Centaurein*, a glucoside

crystallising in small, pale yellow, elongated plates, of no definite m. p., was extracted from the dried roots of *Centaurea Jacea*. It contains 9.96% of water, which is lost at 50° in a vacuum, the glucoside itself remaining unchanged. It has  $[\alpha]_D -76.54^\circ$  ( $-85^\circ$  anhydrous) in methyl-alcoholic solution and  $[\alpha]_D -133.68^\circ$  ( $-148.47^\circ$  anhydrous) in 5% sodium hydroxide solution. Hydrolysis takes place slowly in boiling 5% sulphuric acid, the products being dextrose (33.68%) and *centaureidin* (70.77%), both of which were obtained in crystalline form.

H. J. E.

**Oxalyl Chloride in the Synthesis of the Triphenylmethane Dyes.** HARPER F. ZOLLER (*Science*, 1920, 52, 207).—Oxalyl chloride may be used instead of carbonyl chloride or Michler's ketone in the condensation of aniline and its derivatives, preferably in the presence of fused zinc chloride, for the production of triphenylmethane dyes.

A. A. E.

**$\delta$ -Methylornithine and  $\delta$ -Methylarginine. The Origin of Creatine.** IV. K. THOMAS, J. KAPFFHAMMER, and B. FLASCHEN-TRIGER (*Z. physiol. Chem.*, 1922, 124, 75—102).—Methylarginine, administered to rabbits, does not increase the total creatinine in the urine. The methylarginine required for the experiments was prepared from  $\delta$ -benzoylornithine (Sørensen, A., 1905, i, 600), which is obtained from ornithuric acid, but is contaminated with 3-benzoylamido-2-piperidone, long, white needles, m. p. 184°. On treatment with *p*-toluenesulphonyl chloride and alkali  $\delta$ -*p*-toluenesulphonyl- $\alpha$ -benzoylornithine,  $C_8H_7SO_2NH[CH_2]_3CH(NHBz)CO_2H$ , is formed, fine, white needles, m. p. 160—164° (decomp.). If too little alkali be used, 1-*p*-toluenesulphonyl-3-benzoylamido-piperidone, white needles, m. p. 184°, is obtained as a by-product. Methylation of  $\delta$ -*p*-toluenesulphonyl- $\alpha$ -benzoylornithine with methyl sulphate yields  $\delta$ -*p*-toluenesulphonyl- $\alpha$ -benzoyl- $\delta$ -methylornithine, needles, m. p. 188—189°. Hydrolysis of this compound with acid yields  $\delta$ -*p*-toluenesulphonyl- $\delta$ -methylornithine, thin plates, decomp. 245° (hydrochloride, glistening plates, m. p. 288°), whilst reduction with hydriodic acid and phosphonium iodide at 50—60° yields  $\alpha$ -benzoyl- $\delta$ -methylornithine,  $NHMe[CH_2]_3CH(NHBz)CO_2H$ , a microcrystalline white powder, m. p. 215°. On hydrolysis, dl-methylornithine is formed, isolated as the dihydrochloride, microcrystalline needles or crusts of rhombohedra, m. p. 157° (chloroplatinate,

m. p. 206°; monohydrochloride, m. p. 215—225°). Along with methylornithine is formed 3-amino-1-methyl-2-piperidone, isolated as the chloroplatinate,  $(C_8H_{12}ON_2)_2H_2PtCl_6$ , light yellow, rhombic leaflets, m. p. 210° (picrate,  $C_{12}H_{15}O_8N_5$ , m. p. 207°). The reaction of methylornithine and of aminomethylpiperidone with alkaloid precipitants has been investigated, with particular reference to Winterstein's isomeric lysine.

Treatment of methylornithine with a solution of cyanamide in presence of ammonia yields  $\alpha$ -benzoyl- $\delta$ -methylarginine, decomp. about 265°, and on hydrolysis with acid this yields dl-methylarginine,  $NH_2C(NH)NMe[CH_2]_3CH(NH_2)CO_2H$  [hydrochloride,

$C_7H_{16}O_2N_4 \cdot 2HCl$ , fine needles, aggregated in clumps, decomp.  $215^\circ$ ; *nitrate*,  $C_7H_{16}O_2N_4 \cdot 2HNO_3$ , rhombic prisms, m. p.  $153^\circ$ ; *cupri-nitrate*, fine, dark blue needles containing water of crystallisation, which on dehydrating have the formula  $(C_7H_{16}O_2N_4)_2 \cdot Cu(NO_3)_2$ ; *picrates*,  $C_7H_{16}O_2N_4 \cdot C_6H_3O_7N_3$ , felted needles, decomp.  $207-209^\circ$ , and  $C_7H_{16}O_2N_4 \cdot (C_6H_3O_7N_3)_2$ , m. p.  $145^\circ$ . *d*-Arginine also gives a *dipicrate*,  $C_6H_{14}O_2N_4 \cdot (C_6H_3O_7N_3)_2$ , m. p.  $198-199^\circ$ . Arginase does not act on methylarginine. W. O. K.

**The Reduction of Morphine by Emde's Method.** FRANZ FALTIS and THEODOR HECKZO (*Monatsh.*, 1922, 43, 255-267; cf. Faltis and Krausz, A., 1922, i, 676).—In the first part of the paper the influence of structure on the rupture of cyclic quaternary ammonium bases into tertiary bases by treatment with sodium amalgam (Emde's method, *loc. cit.*) is discussed. The course of the reaction is specially influenced, in condensed systems, by the position of a phenyl group in relation to the ring-nitrogen. In the previous paper the reaction was applied to dimethylpomorphine methochloride. It has now been extended to morphine itself in the form of dimethylmorphine methochloride. The product is identical with the  $\alpha$ -dimethylmorphimethine previously obtained by Pschorr (A., 1911, i, 908) by Hofmann's method. The rupture of the ring therefore takes place without reduction, and it is further shown that sodium amalgam has no reducing action on  $\alpha$ -dimethylmorphimethine methochloride. E. H. R.

**The Pilocarpine Series. I. Nitropilocarpine and Nitro-isopilocarpine.** MAX POLONOVSKI and MICHEL POLONOVSKI (*Bull. Soc. chim.*, 1922, [iv], 31, 1027-1045; cf. Jowett, T., 1900, 77, 851; 1901, 79, 580 and 1331; 1903, 83, 438).—Whilst direct nitration of pilocarpine cannot be effected, the action of excess of concentrated sulphuric acid on pilocarpine nitrate gives an 80% yield of *nitropilocarpine*,  $NO_2 \cdot C_{11}H_{15}O_3N_2$ , hard, white, prismatic needles, m. p.  $135-136^\circ$ . The introduction of a nitro-group into the molecule causes pilocarpine to lose its basic character. The authors consider it probable that the entering group is attached to the 5-carbon atom in the iminazole ring. The substance is stable towards many reagents, and does not undergo isomerisation on being heated; it is attacked, however, by alkalis, being partly delactonised and partly isomerised, the change taking place very rapidly in cold alcoholic solution. The alkaline solution on acidification with acetic acid yields a white, crystalline precipitate of *nitropilocarpic acid*,  $NO_2 \cdot C_{11}H_{17}O_3N_2$ , m. p.  $199^\circ$ , which loses water on being heated at  $200-205^\circ$ , forming *nitropilocarpine*. The sodium and barium salts were prepared. Reduction of *nitropilocarpine* may be effected by various means; three molecules of hydrogen being utilised per molecule of alkaloid, but no reduction derivative was isolated. The stability of pilocarpine is considerably modified by introduction of the nitro-group; the nitro-derivative on prolonged boiling with excess of baryta water is decomposed with formation of barium cyanide and formate and the barium salts of pilopie and homopilopie acids, together with other

substances. The reaction is very complex owing to the formation of intermediate substances which react further, giving rise to secondary products. Pilopic and homopilopic acids may function either as monobasic, lactonic, or dibasic acids. Barium salts of the former type are obtained from the action of barium carbonate on the acid with subsequent filtration and evaporation to dryness, of the latter on heating the acid with baryta water, excess of which is eliminated with carbon dioxide. The constitution of pilocarpine is discussed but is not yet completely elucidated.

*Nitroisopilocarpine*, prepared similarly to nitropilocarpine, crystallises in small, white prisms, m. p.  $93-94^{\circ}$ , and forms salts with dilute alkalis, but is readily relactonised, yielding the original substance. Pilocarpine and isopilocarpine suffer similar decompositions with formation of the same products, but there is this difference, homopilopic acid appears to be formed in greater quantity from pilocarpine than is pilopic from nitropilocarpine; with the isomeride and its nitro-derivative the converse is the case. No evidence as to the nature of the isomerism was obtainable from the decomposition products, but it is pointed out that prolonged heating with baryta water may transform nitropilocarpine into its isomeride as a preliminary to decomposition. Both substances, however, yield methylamine at the outset, so that if isomerisation occurs, as suggested, the change affects, not the original substances, but their primary decomposition products.

H. J. E.

**Phosphates of Strychnine.** J. BOUILLON (*J. Pharm. Chim.*, 1922, [vii], 26, 406—415).—Strychnine forms two phosphates by the direct union of the acid and the base under suitable conditions. The monobasic phosphate of the formula  $C_{21}H_{22}O_2N_2 \cdot H_3PO_4 \cdot 2H_2O$  was obtained by dissolving 3.34 g. of strychnine in 100 c.c. of water containing the calculated quantity of phosphoric acid. On cooling, the salt crystallised in fine needles. The dibasic salt,  $(C_{21}H_{22}O_2N_2)_2 \cdot H_3PO_4 \cdot 9H_2O$ , was obtained by combination of the theoretical amounts of strychnine and phosphoric acid in 80% alcohol. The hot solution slowly deposited the salt in glistening leaflets. It is but slightly soluble in water, and is partly dissociated by this solvent into the monobasic phosphate and free strychnine. It has  $[\alpha]_D -43.13^{\circ}$  in 80% alcohol. A tribasic phosphate could not be obtained, a solution of the acid and base in the requisite proportions depositing only crystals of the dibasic salt and strychnine.

**Derivatives of Pyridine obtained from Diacetonitrile and Benzoacetodinitrile.** ERICH BENARY and GERTRUD LÖWENTHAL (*Ber.*, 1922, 55, [B], 3429—3434).—In a previous communication (Benary, A., 1921, i, 127), the transformation of ethyl 2:6-dimethyl-4-cyanomethyl-1:4-dihydropyridine-3:5-dicarboxylate into ethyl 5-methyl-3-cyanomethylpyrrole-2-carboxylate has been described. A number of compounds which might possibly suffer a similar conversion of the pyridine into the pyrrole ring have now been examined, but in no case has this change been observed, so that the reaction does not appear to be general.

Imidoacetoacetonitrile and  $\alpha\beta$ -dichloroethyl ether yield 2:6-dimethyl-4-chloromethyl-1:4-dihydropyridine-3:5-dicarboxylonitrile,

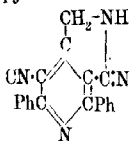

colourless leaflets, m. p.  $170^\circ$ , which is transformed by a solution of potassium cyanide in methyl alcohol into a mixture of 2:6-dimethyl-4-cyanomethyl-1:4-dihydropyridine-3:5-dicarboxylonitrile, colourless crystals, m. p.  $220^\circ$ , and (?) 2:6-dimethyl-4-carbamido-methyl-1:4-dihydropyridine-3:5-dicarboxylonitrile, colourless leaflets, m. p.  $109^\circ$ . 2:6-Dimethyl-4-cyanomethylpyridine-3:5-dicarboxylonitrile, colourless leaflets, m. p.  $230^\circ$  (decomp.), is conveniently prepared by the action of sodium nitrite on a solution of the corresponding dihydro-compound in glacial acetic acid. The oxidation of 2:6-dimethyl-4-chloromethyl-1:4-dihydropyridine-3:5-dicarboxylonitrile to the pyridine derivative cannot be effected by reason of the unusual lability of the chlorine atom; the action of sodium nitrite on a solution of the compound in glacial acetic acid leads to the production of 3:5-dicyano-2:6-dimethyl-1:4-

dihydropyridine-4-aldoxime,  $\text{NH} \begin{array}{c} \text{CMe:C(CN)} \\ \text{CMe:C(CN)} \end{array} > \text{CH}\cdot\text{CH}\cdot\text{NOH}$ , prismatic needles, decomp.  $161^\circ$  after darkening at about  $157^\circ$ , which is further characterised by its conversion into a benzoate, colourless needles or leaflets, m. p.  $186^\circ$  after softening at  $176^\circ$ , and an acetate, long, colourless needles, m. p.  $115^\circ$ .

2:6-Diphenyl-4-chloromethyl-1:4-dihydropyridine-3:5-dicarboxylonitrile,  $\text{NH} \begin{array}{c} \text{CPh:C(CN)} \\ \text{CPh:C(CN)} \end{array} > \text{CH}\cdot\text{CH}_2\text{Cl}$ , colourless leaflets, m. p.  $235^\circ$ , prepared from  $\alpha\beta$ -dichlorodiethyl ether and imidobenzoylacetonitrile, is not affected by sodium nitrite and glacial acetic acid, but is oxidised by nitric acid to 2:6-diphenyl-4-chloromethylpyridine-3:5-dicarboxylonitrile, long, colourless needles, m. p.  $177^\circ$ . The chlorodihydro-compound is converted by an alcoholic solution of potassium cyanide into 2:6-diphenyl-4-cyanomethyl-1:4-dihydropyridine-3:5-dicarboxylonitrile, pale brown leaflets, m. p.  $185^\circ$ .

Boiling aqueous potassium hydroxide solution converts 2:6-diphenyl-4-chloromethylpyridine-3:5-dicarboxylonitrile into 2:6-diphenyl-4-hydroxymethylpyridine-3:5-dicarboxylonitrile, colourless, slender needles, m. p.  $176^\circ$ , whereas alcoholic ammonia transforms it into a substance, pale brown needles, m. p.  $198^\circ$ , to which, on account of the absence of basic properties, the annexed constitution is ascribed.

H. W.

**Some  $\delta$ -Ketonic Nitriles and their Relation to Cyclic Compounds.** E. P. KOHLER, ALICE GRAUSTEIN, and D. R. MERRILL (*J. Amer. Chem. Soc.*, 1922, **44**, 2536—2556; cf. A., 1922, i, 461).—In the presence of a small amount of sodium methoxide and in very dry methyl alcohol, methyl cyanoacetate combines with  $\alpha\beta$ -unsaturated ketones and forms  $\gamma$ -ketonic nitriles. In indifferent media, these are rapidly converted by the action of halogen acids

into equilibrium mixtures containing small quantities of these nitriles mixed with isomeric tetrahydropyridine derivatives. This process takes place very rapidly, so that the open-chain compounds and their cyclic isomerides give the same products in reactions that take place in the presence of acids. Where bases are used, the products obtained from the two types are different. The cyclic compounds react very readily with the halogens and by alternately introducing halogen and eliminating halogen acid it is possible to go step by step from the tetrahydropyridine derivative to true pyridines. With the open-chain compounds, the action of halogens results in a mixture of a great number of open-chain and cyclic halogenated compounds, but the action can be controlled. Halogenation in the presence of potassium acetate gives open-chain compounds only, whilst the same process in glacial acetic acid gives mainly a true pyridine derivative. These reactions have been studied in the case of phenyl styryl ketone and *p*-chlorophenyl styryl ketone. The products from the two ketones behave alike, but the products from the chloro-derivatives generally are less fusible and less soluble than those from the chlorine-free substance.

Phenyl styryl ketone and methyl cyanoacetate condense together to give methyl  $\alpha$ -cyano- $\gamma$ -benzoyl- $\beta$ -phenylbutyrate,

$$\text{COPh}\cdot\text{CH}_2\cdot\text{CHPh}\cdot\text{CH}(\text{CN})\cdot\text{CO}_2\text{Me},$$

m. p.  $76^\circ$ , together with some of the trimolecular compound, m. p.  $220^\circ$ , formed by the addition of a second molecule of the unsaturated ketone. Methyl  $\alpha$ -cyano- $\gamma$ -*p*-chlorobenzoyl- $\beta$ -phenylbutyrate, m. p.  $126^\circ$ , and the trimolecular compound, m. p.  $230$ – $232^\circ$ , were similarly prepared. Using methyl  $\alpha$ -cyanopropionate instead of the cyanoacetate, the product in the latter case was methyl  $\alpha$ -cyano- $\gamma$ -*p*-chlorobenzoyl- $\beta$ -phenyl- $\alpha$ -methylbutyrate, in two stereoisomeric forms, m. p.  $108^\circ$  and  $92^\circ$ , respectively. When hydrolysed in acid medium the esters described above give ester acids, but when carefully hydrolysed with alcoholic potash the cyano-acid is the product. The compounds described are methyl hydrogen  $\gamma$ -benzoyl- $\beta$ -phenylethylmalonate, m. p.  $160^\circ$  (decomp.),  $\alpha$ -cyano- $\gamma$ -benzoyl- $\beta$ -phenylbutyric acid, m. p.  $160^\circ$  (decomp.), and  $\gamma$ -benzoyl- $\beta$ -phenylbutyronitrile, m. p.  $76^\circ$ , obtained by decomposing the latter at  $200^\circ$ .

The tetrahydropyridine derivatives described are methyl 6-keto-2:4-diphenyltetrahydropyridine-5-carboxylate, m. p.  $165$ – $166^\circ$ , and the free acid, m. p.  $130^\circ$  (decomp.); 6-keto-2:4-diphenyltetrahydropyridine, m. p.  $130^\circ$ ; methyl 6-keto-4-phenyl-2-*p*-chlorophenyltetrahydropyridine-5-carboxylate, m. p.  $204^\circ$ . On careful bromination, these tetrahydropyridine derivatives give monobromo-derivatives, but if the bromination is conducted at too high a temperature the product is contaminated with the corresponding dihydropyridine derivative. Methyl 3-bromo-6-keto-2:4-diphenyltetrahydropyridine-5-carboxylate had m. p.  $160$ – $161^\circ$ , and, on digestion with sodium methoxide in methyl alcohol, gives methyl 6-hydroxy-2:4-diphenylpyridine-5-carboxylate, the free acid of which has m. p.  $253^\circ$  (decomp.) and on heating at  $260^\circ$  decomposes, giving 6-hydroxy-2:4-diphenylpyridine. The monobromo-ester described above on further

bromination yields *methyl 3:5-dibromo-6-keto-2:4-diphenyltetrahydropyridine-5-carboxylate*, m. p. 160° (decomp.) and when a solution of this compound in dry methyl alcohol is rapidly saturated with hydrogen bromide it gives ammonium bromide, *methyl  $\alpha$ -dibromobenzoylphenylethylmalonate*, and *methyl  $\alpha$ -dibromo- $\gamma$ -benzoyl- $\beta$ -phenylethylmalonate*, m. p. 180°, an isomeride, m. p. 140°, of which was obtained during the earlier bromination. These two isomerides were decomposed on heating, giving *4-bromo-4-cyano-2-benzoyl-3-phenyltetrahydrofuran*, m. p. 275°. If the further bromination described above is carried out in boiling chloroform, the dibromo-compound loses hydrogen bromide and forms *methyl 3-bromo-6-hydroxy-2:4-diphenylpyridine-5-carboxylate*, m. p. 233—240°, which does not undergo further bromination, but gives a *perbromide*. The free acid has m. p. 270° (decomp.), and on heating gives *3-bromo-6-hydroxy-2:4-diphenylpyridine*. Similar bromination products from the *p*-chlorophenyl derivatives are *methyl 3-bromo-6-keto-4-phenyl-2-p-chlorophenyltetrahydropyridine-5-carboxylate*, m. p. 194°, *methyl 3:5-dibromo-6-keto-4-phenyl-2-p-chlorophenyltetrahydropyridine-5-carboxylate*, m. p. 183°, and *methyl 6-hydroxy-4-phenyl-2-p-chlorophenylpyridine-5-carboxylate*, m. p. 262°.

Bromination of the methyl cyanoacetate additive products in the presence of potassium acetate gave the following compounds: *methyl  $\alpha$ -bromo- $\alpha$ -cyano- $\gamma$ -benzoyl- $\beta$ -phenylbutyrate*, m. p. 130°; *methyl  $\alpha$ -dibromo- $\alpha$ -cyano- $\gamma$ -benzoyl- $\beta$ -phenylbutyrate*, m. p. 177—179°; *methyl  $\alpha$ -bromo- $\alpha$ -cyano- $\gamma$ -p-chlorobenzoyl- $\beta$ -phenylbutyrate*, in the form of two isomerides, m. p. 91—92° and 123°, respectively; *methyl  $\alpha$ -dibromo- $\alpha$ -cyano- $\gamma$ -p-chlorobenzoyl- $\beta$ -phenylbutyrate*, m. p. 193°. Products of bromination in glacial acetic acid are: *methyl 6-bromo-2:4-diphenylpyridine-5-carboxylate*, m. p. 147°, and its free acid, m. p. 206—208°; *methyl 6-bromo-4-phenyl-2-p-chlorophenylpyridine-5-carboxylate*, m. p. 106°.

Chlorination of the same additive products in chloroform solution gave excellent yields of open-chain substitution products. In this way, the authors prepared *methyl  $\alpha$ -chloro- $\alpha$ -cyano- $\beta$ -phenyl- $\gamma$ -p-chlorophenylbutyrate*, obtained in two stereoisomeric forms, m. p. 80° and 106°, respectively. A chloroform solution of the isomeride with the higher m. p. when saturated with hydrogen bromide and boiled for several hours gave a compound, m. p. 19° (decomp.), which is probably *methyl 5-chloro-6-keto-4-phenyl-2-p-chlorophenyltetrahydropyridine-5-carboxylate*. This ester reacts readily with chlorine and passes into *methyl 3-chloro-6-hydroxy-4-phenyl-2-p-chlorophenylpyridine-5-carboxylate*, m. p. 196°, and on further chlorination into *methyl 3:4:5-trichloro-6-keto-4-phenyl-2-p-chlorophenyltetrahydropyridine-5-carboxylate*.

cycloPropane derivatives are obtained by heating the  $\alpha$ -bromo-esters described above with potassium acetate in a suitable solvent; by removing hydrogen chloride from  $\alpha$ -chloro-compounds, or by eliminating bromine from  $\alpha$ -dibromo-compounds with potassium iodide. These processes gave stereoisomeric cyclopropane derivatives of which the following are described: *methyl 1-cyano-*

3-benzoyl-2-phenylcyclopropane-1-carboxylate, the three isomeric forms of which had m. p. 106°, 110°, and 178–180°, respectively; the free acid, m. p. 230° (decomp.), corresponding with these esters, and methyl 1-cyano-2-phenyl-3-p-chlorophenylcyclopropane-1-carboxylate, the two isomeric forms of which had m. p. 132° and 180°, respectively. W. G.

**$\alpha$ -Diketones of the Indole Group. I. G. SANNA** (*Gazzetta*, 1922, 52, ii, 165–170).—In addition to the products already described (Oddo and Sanna, A., 1922, i, 371), the action of oxalyl chloride on magnesium indolyl bromide yields 2:2-indil, 2:3-indil, and 1:2-indil; 3:3-indil is also formed in traces, in some cases, but not at all in others.

3:3-Indilphenylosazone,  $[\text{C}_8\text{H}_6\text{N}\cdot\text{C}(\text{N}\cdot\text{NHPh})\cdot]_2$ , crystallises in yellow prisms, m. p. 158° (decomp.), and when heated with alcohol and ferric chloride undergoes oxidation to the corresponding osotetrazone.

2:3-Di-3'-indolylquinoxaline,  $\text{C}_8\text{H}_4 \begin{smallmatrix} \text{N}:\text{C}-\text{C}_6\text{H}_5\text{N} \\ \text{N}:\text{C}-\text{C}_6\text{H}_5\text{N} \end{smallmatrix}$ , obtained by the condensation of 3:3-indil with *o*-phenylenediamine, forms masses of brick-red prisms, m. p. 163° (decomp.), and gives the general reactions of the quinoxalines.

3:3-Indil forms a silver derivative,  $\text{C}_{18}\text{H}_{10}\text{O}_2\text{N}_2\text{Ag}_2$ , as a grey precipitate, and yields indole-3-carboxylic acid when oxidised by means of hydrogen peroxide.

2:2-Indil (2:2-di-indolyl),  $\text{C}_{18}\text{H}_{12}\text{O}_2\text{N}_2$ , forms pale yellow, tabular prisms, m. p. 273°, and has the normal molecular weight in freezing acetic acid. The phenylosazone,  $\text{C}_{30}\text{H}_{24}\text{N}_6$ , crystallises in yellow, tabular prisms, m. p. 170° (decomp.), and is oxidised by ferric chloride to the corresponding osotetrazone. When oxidised by means of hydrogen peroxide or fused with potassium hydroxide, 2:2-indil yields indole-2-carboxylic acid.

2:3-Di-2'-indolylquinoxaline,  $\text{C}_{24}\text{H}_{16}\text{N}_4$ , crystallises in tufts of red, acicular prisms, m. p. 154° (decomp.), and shows the general reactions of the quinoxalines.

Bis-1:2-indil (bis-1:2-di-indolyl) (annexed formula), also obtained from the products of the action of oxalyl chloride on magnesium indolyl bromide, crystallises in yellow scales, m. p. 320°; when heated in a reflux apparatus with concentrated potassium hydroxide, it yields 2:2-indil, and when fused with potassium hydroxide, indole-2-carboxylic acid.

A compound, forming white crystals, m. p. 163°, also occurs among the products of the reaction, but has not been characterised. T. H. P.

**Syntheses of  $\beta$ -Diketones in the Indole Group. I. G. SANNA** (*Gazzetta*, 1922, 52, ii, 170–176).—The action of malonyl chloride on magnesium indolyl bromide proceeds similarly to that on magnesium pyrrol bromide (Oddo and Dainotti, A., 1912,

i, 721) and yields di-3-indoylmethane. In many of its reactions this compound behaves, like all  $\beta$ -diketones, as a hydroxy-ketone, but in the solid state and also in solution it appears to exist principally in the normal diketonic form, being transformed, slowly at the ordinary temperature but rapidly when heated, into the keto-enolic modification. Attempts to separate the two tautomeric forms were unsuccessful, but indicated great stability in the normal modification. Since only the 3:3'-compound was obtained in the above reaction, the greater length of the chain in malonyl chloride appears to enhance the tendency to attack in the position of the indole nucleus most remote from the imino-group.

Di-3-indoylmethane,  $\text{CH}_2(\text{CO}-\text{C} \begin{smallmatrix} \text{C}_6\text{H}_4 \\ \text{CH} \end{smallmatrix} \text{>NH})_2$ , crystallises in cotton-like masses of minute, white needles, blackening at about  $230^\circ$ , m. p.  $287^\circ$  (decomp.), and is highly resistant to the action of alkali hydroxide or concentrated sulphuric acid. In alcoholic solution it gives with ferric chloride an immediate emerald-green coloration, which tends to darken and to assume a violet reflection. With cupric acetate in alcoholic solution, it gives a greenish-yellow liquid which, on cooling, deposits the copper salt,  $(\text{C}_{16}\text{H}_{12}\text{O}_2\text{N}_2)_2\text{Cu}$ , crystallising in brownish-red prisms, m. p.  $254^\circ$  (decomp.). With ammoniacal silver nitrate it forms the silver derivative,

as a white, curdy precipitate; the formation of this compound shows that the hydrogen replaced by the chain is not the imine hydrogen. Hydrolysis of di-indoylmethane by means of alkali hydroxide yields indole-3-carboxylic acid and 3-indolyl methyl ketone (3-acetylindole).

Di-indoylmethane reacts readily with phenylhydrazine, giving the dehydration product of the monophenylhydrazone, namely, 1-phenyl-3:5-di-indolylpyrazole,  $\begin{smallmatrix} \text{C}_6\text{H}_4 & \text{C} & \text{C} & \text{CH} & \text{C} & \text{C} & \text{C}_6\text{H}_4 \\ | & | & | & | & | & | \\ \text{NH} & \text{CH} & \text{N} & \text{---} & \text{NPh} & \text{CH} & \text{NH} \end{smallmatrix}$ , which

crystallises in yellow prisms resembling knife-blades, m. p.  $236^\circ$  (decomp.), and is converted into the corresponding pyrazoline base when reduced by means of sodium. The reaction with hydroxylamine proceeds similarly, yielding 3:5-di-indolylisooxazole,

which crystallises in yellow prisms, m. p.  $219^\circ$  (decomp.), and exhibits feebly basic properties; restriction of the action of the hydroxylamine results in the formation of a compound which crystallises in slender, red needles, m. p. about  $170^\circ$  (decomp.), and is possibly the mono-oxime of the diketone, as it exhibits reducing properties and yields di-indoylmethane when boiled with dilute hydrochloric acid.

Condensation of di-indoylmethane with semicarbazide results in the formation of di-indolylpyrazolecarboxylamide,

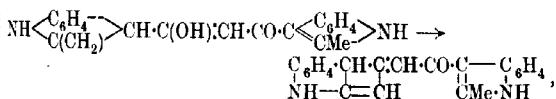

which then takes up a molecule of water and loses ammonia and carbon dioxide, giving 3:5-di-indolylpyrazole,  $\text{C}_8\text{NH}_8 \cdot \text{C} \cdot \text{CH} \cdot \text{C} \cdot \text{C}_8\text{NH}_8$ ,  $\begin{smallmatrix} \text{N} & \text{---} & \text{NH} \\ | & & | \end{smallmatrix}$ , which forms yellow crystals, m. p. 229° (decomp.), and on reduction with sodium yields the corresponding pyrazoline; the latter, like 1-phenyl-3:5-di-indolylpyrazole, gives a violet coloration with sulphuric acid and potassium dichromate, and a bright purple coloration with nitrous acid.

T. H. P.

**Syntheses of  $\beta$ -Diketones in the Indole Group. II. G. SANNA** (*Gazzetta*, 1922, 52, ii, 177—184; cf. preceding abstract).—The action of malonyl chloride on magnesium 2-methylindolyl bromide yields di-2-methyl-3-indolylmethane,

which is closely analogous to its lower homologue and exhibits all the reactions characteristic of the  $\beta$ -diketones. It dissolves readily in cold alkali hydroxide solution and is reprecipitated unchanged on addition to the solution of dilute sulphuric acid. With ferric chloride, its alcoholic solution gives an intense emerald-green coloration quickly changing to violet. When boiled with alkali hydroxide solution it gives 2-methylindole-3-carboxylic acid and 2-methyl-3-indolyl methyl ketone, and with phenylhydrazine, hydroxylamine, and semicarbazide it reacts similarly to the lower homologue. The above compound, which must be regarded as the hydroxyketonic form,  $\cdot \text{C} \cdot \text{C}(\text{OH}) \cdot \text{CH} \cdot \text{CO} \cdot$ , is accompanied by an isomeride which is insoluble in alkali hydroxide solution, yields no coloration in the cold with ferric chloride, is not precipitated by cupric acetate or esterified by phenylcarbimide, and appears to be the normal diketonic form containing the grouping  $\cdot \text{CO} \cdot \text{CH}_2 \cdot \text{CO} \cdot$ . In addition to these two compounds, a third, which is formed in small proportion, has the composition of an anhydro-compound and may be formed by dehydration of the mixed keto-enolic modification:

or may represent the result of condensation between the dimethylindolylmethane (1 mol.) and 2-methylindole (2 mols.).

Di-2-methyl-3-indolylmethane crystallises in yellow, rhomboedral plates, m. p. 219°, and has the normal molecular weight in freezing acetic acid. The hydroxy-ketonic tautomeride forms a yellow, microcrystalline powder or prismatic rods, m. p. 219°, and has the calculated molecular weight in freezing acetic acid, but differs from the preceding compound in its solubility in organic solvents.

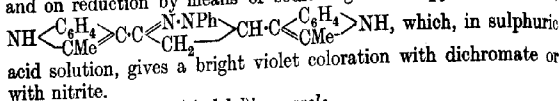

From the latter compound the following derivatives are obtainable. The cupric derivative,  $\text{C}_{21}\text{H}_{16}\text{O}_2\text{N}_2\text{Cu}$ , forms a yellow powder

or octahedra with violet reflection, m. p. 220° (decomp.); the silver derivative,  $C_{21}H_{18}O_2N_2Ag_2$ , was also prepared.

1-Phenyl-3 : 5-di(2'-methyl-3'-indolyl)pyrazole,

obtained by condensation with phenylhydrazine, crystallises in serrate aggregates of pale yellow prisms, m. p. 192° (decomp.), and on reduction by means of sodium gives the pyrazoline base,

3 : 5-Di(2'-methyl-3'-indolyl)isoxazole,

prepared by the action of hydroxylamine, crystallises in pale yellow prisms, m. p. 174° (decomp.), and exhibits basic properties more marked than those of the corresponding indole derivative; its hydrochloric acid solution is rendered turbid by ammonia, platinum chloride, or auric chloride.

3 : 5-Di(2'-methyl-3'-indolyl)pyrazole,

obtained by condensation with semicarbazide, crystallises in minute, yellow needles, m. p. 247° (decomp.), and is reduced by sodium to the corresponding pyrazoline derivative, which yields violet colorations when treated in sulphuric acid solution with dichromate or sodium nitrite.

The anhydro-compound (see above),  $C_{21}H_{18}O_2N_2 \cdot H_2O$ , forms short, stout, yellow, hexagonal prisms, m. p. 224° (decomp.).

T. H. P.

### Conversion of $\beta$ -Phenylhydroxylamine into Quinoline Bases.

E. BAMBERGER and H. WEITNAUER (*Ber.*, 1922, 55, [B], 3376—3382).—Quinoline is prepared in very small yield by the action of glycerol and sulphuric acid on  $\beta$ -phenylhydroxylamine (cf. Hindermann, *Diss. Zurich*, 1897). Replacement of glycerol by acetaldehyde, which is generally assumed to be an intermediate product in Skraup's synthesis of quinoline, leads to slightly better results. The intermediate *nitron*,  $O:NPh:CH:CH:CH_2$ , could only be isolated in an impure, amorphous, resinous form; when heated at a relatively somewhat high temperature and subsequently treated with dilute sulphuric acid, it gives quinoline in quantity which never exceeds 5% of that theoretically possible. Crotonaldehyde and  $\beta$ -phenylhydroxylamine give 2-methylquinoline. Cinnamaldehyde condenses with phenylhydroxylamine to give phenylacryl-*N*-phenylnitron,  $O:NPh:CH:CH:CHPh$ , yellow needles, m. p. 155—156°, when rapidly heated, which is transformed by a little concentrated sulphuric acid in the presence of glacial acetic acid into 2-phenylquinoline, m. p. 82.5—83°.

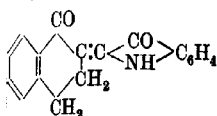

The present synthesis differs from that of Skraup in that it is

not necessary to provide an external source of the necessary oxygen atom, the latter being contained in the phenylhydroxylamine.

**Reactivity of Methyl Groups in Heterocyclic Bases.** WILLIAM HOBSON MILLS and JAMES LEONARD BRIERLEY SMITH (T., 1922, 121, 2724—2737).

**Dyes Derived from  $\alpha$ -Ketotetrahydronaphthalene [ $\alpha$ -Tetra-  
lone].** WALTER HERZOG and J. KREIDL (Ber., 1922, 55, [B],  
3394—3400).—2-Tetrahydronaphthalene-2'-indoleindigotin [1-Keto-  
2:(2')-indoxyltetrahydronaphthalene] (annexed formula) is obtained

when equivalent quantities of  $\alpha$ -keto-  
tetrahydronaphthalene and  $\alpha$ -isatinil  
are heated under a reflux condenser in  
the presence of light petroleum (b. p.  
150—200°). It forms bluish-violet  
crystals with a bronze reflex, decomp.

about 250°. It is transformed by fuming sulphuric acid into  
sulphonic acid which gives a pure blue solution in water.  
With alkali and hyposulphite, it yields a yellow vat from which  
wool and cotton are dyed in pure blue tones. 1-Keto-2:3'-oxy-  
thionaphthentetrahydronaphthalene, reddish-violet needles, de-  
comp. about 250°, is prepared by the action of 2-ketotetra-  
hydronaphthalene on  $\alpha$ -thionaphthenquinoneanil in boiling acetic  
anhydride solution. It is sulphonated by fuming sulphuric acid.  
With alkali and hyposulphite, it gives a greenish-yellow vat  
from which wool is dyed in dark brownish-violet, cotton in reddish-  
violet shades. Attempts to condense  $\alpha$ -ketotetrahydronaphthalene  
with  $\beta$ -isatinil were unsuccessful.

$\alpha$ -Ketotetrahydronaphthalene reacts with terephthalaldehyde in  
alcoholic solution in the presence of sodium hydroxide to yield  
the compound  $C_6H_4 \begin{matrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CH} \cdot \text{CH} \cdot C_6H_4 \cdot \text{CH} \cdot \text{CH} \\ \diagdown \quad \diagup \\ \text{CH}_2 \cdot \text{CH}_2 \end{matrix} \begin{matrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CH} \cdot \text{CH} \cdot C_6H_4 \cdot \text{CH} \cdot \text{CH} \\ \diagdown \quad \diagup \\ \text{CH}_2 \cdot \text{CH}_2 \end{matrix} C_6H_4$ , straw-  
yellow crystals, m. p. (indefinite) 240—255° after darkening at 230°,  
from which a vat could not be obtained.  $\alpha$ -Ketotetrahydronaph-  
thalene, terephthalaldehyde, and 3-hydroxythionaphthen yield  
mainly a substance, small golden-yellow needles, m. p. 192—193°  
the constitution of which has not yet been elucidated), and in

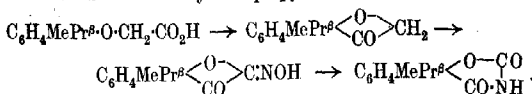

minor amount the dye  $C_6H_4 \begin{matrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CH} \cdot \text{CH} \cdot C_6H_4 \cdot \text{CH} \cdot \text{CH} \\ \diagdown \quad \diagup \\ \text{CH}_2 \cdot \text{CH}_2 \end{matrix} C_6H_4$ .

Cinnamaldehyde and  $\alpha$ -ketotetrahydronaphthalene yield  $\beta$ -cinn-  
mylidene- $\alpha$ -ketotetrahydronaphthalene,  $C_6H_4 \begin{matrix} \text{CO} \\ \diagup \quad \diagdown \\ \text{CH} \cdot \text{CH} \cdot C_6H_4 \cdot \text{CH} \cdot \text{CH} \\ \diagdown \quad \diagup \\ \text{CH}_2 \cdot \text{CH}_2 \end{matrix} C_6H_4 \cdot \text{CH} \cdot \text{CH} \cdot \text{CHPh}$ ,  
large, yellow leaflets, m. p. 132—134°, which becomes polymerised at  
220—230°.

H. W.

**1:3-Benzoxazine. I. Conversion of Oximinocoumaran-  
ones into 1:3-Benzoxazine Derivatives.** EFISIO MAMELI  
Gazzetta, 1922, 52, ii, 184—189).—4-Methyl-7-isopropyl-3-coumar-  
anone, obtained from thymoxyacetic acid, when treated with  
nitrous acid, gives 2-oximino-4-methyl-7-isopropylcoumaranone,

which is converted by the action of phosphorus pentachloride into 2:4-diketo-5-methyl-8-isopropyl-1:3-benzoxazine:

This reaction represents the ordinary Beckmann transposition of the type  $\text{R}\cdot\text{C}\begin{array}{c} \text{CO} \\ \diagup \quad \diagdown \\ \text{NOH} \end{array}\text{R}' \rightarrow \text{R}\cdot\text{C}\begin{array}{c} \text{OH} \\ \diagup \quad \diagdown \\ \text{N}\cdot\text{CO}\cdot\text{R}' \end{array} \rightarrow \text{R}\cdot\text{C}\begin{array}{c} \text{O} \\ \diagup \quad \diagdown \\ \text{NH}\cdot\text{CO}\cdot\text{R}' \end{array}$  which

has been observed, together with that of the type  $\text{R}\cdot\text{C}\begin{array}{c} \text{CO}\cdot\text{R}' \\ \diagup \quad \diagdown \\ \text{NOH} \end{array} \rightarrow$

$\text{R}\cdot\text{C}\begin{array}{c} \text{COR}' \\ \diagup \quad \diagdown \\ \text{N} + \text{OH} \end{array}$ , with certain other nitrosoketones. The action of phos-

phorus pentachloride on cyclic oximinoketones, such as oximinocamphor and oximinohydrindones, results in the opening of the nucleus. The above transposition is the first observed instance of the transformation of a pentagonal furan ring into a hexagonal oxazine ring. The constitution of 2:4-diketo-5-methyl-8-isopropyl-1:3-benzoxazine is confirmed by its conversion, when heated with dilute aqueous or alcoholic sodium hydroxide solution, into *o*-thymotamide, which was prepared also by the action of ammonia on ethyl thymotate.

2:3-Diketo-5-methyl-8-isopropyl-1:3-benzoxazine,  $\text{C}_{12}\text{H}_{13}\text{O}_3\text{N}$ , crystallises in a mass of slender, white needles or scales, m. p. 152–153°, decomposing at 177°, and with ferric chloride in either aqueous or benzene solution gives no coloration in the cold and a straw-yellow coloration when heated; it yields no coloration with concentrated sulphuric acid and is not precipitated by picric acid in alcoholic solution. The potassium salt,  $\text{C}_{12}\text{H}_{12}\text{O}_3\text{NK}$ , forms a voluminous, white precipitate, the methyl ester, white needles, m. p. 129°, and the ethyl ester, a white, crystalline powder, m. p. 104°.

*o*-Thymotamide,  $\text{OH}\cdot\text{C}_6\text{H}_4\text{MePr}^s\cdot\text{CO}\cdot\text{NH}_2$ , forms bundles of white needles, m. p. 137°, decomposing at 205°, and gives with ferric chloride a blue coloration in aqueous solution and a green or violet coloration, changing to reddish-violet when heated in benzene solution. It remains unchanged when boiled with concentrated hydrochloric acid, gives no coloration with sulphuric acid, and is not precipitated by picric acid in alcoholic solution. T. H. P.

**Dyes derived from *xx'*-Dicyanodibenzyl Diketone.** SIKH-BHUSHAN DUTT and NIRMAL KUMAR SEN (T., 1922, 121, 2663–2667).

**The Substituted Thiocarbamides. III. The Synthesis of Thiazolidine and Thiazan Derivatives.** F. B. DAINS, R. Q. BREWSTER, J. S. BLAIR, and W. C. THOMPSON (*J. Amer. Chem. Soc.*, 1922, 44, 2637–2643).—Arylallyl amines react with thiocarbimides to give  $\alpha$ -allyl- $\alpha$ , $\beta$ -diarylthiocarbamides, and these, by the action of acetyl chloride or on heating with hydrochloric acid, suffer rearrangement to 2:3-disubstituted thiazolidines. The

following are described.  $\alpha\beta$ -Diphenyl- $\alpha$ -allylthiocarbamide, m. p. 111°;  $\alpha$ -phenyl- $\beta$ -p-bromophenyl- $\alpha$ -allylthiocarbamide, m. p. 123°;  $\alpha$ -phenyl- $\beta$ -p-tolyl- $\alpha$ -allylthiocarbamide, m. p. 107°;  $\beta$ -phenyl- $\alpha$ -p-tolyl- $\alpha$ -allylthiocarbamide, m. p. 91.5°;  $\beta$ -p-bromophenyl- $\alpha$ -p-tolyl- $\alpha$ -allylthiocarbamide, m. p. 121°;  $\alpha\beta$ -di-p-tolyl- $\alpha$ -allylthiocarbamide, m. p. 113°; 2-phenylimino-3-phenyl-5-methylthiazolidine, n. p. 98°, and its *picrate*, m. p. 168—169°; 2-p-bromophenylimino-3-phenyl-5-methylthiazolidine, m. p. 106°; 2-p-tolylimino-3-phenyl-5-methylthiazolidine, an oil, and its *picrate*, m. p. 188°; 2-phenylimino-3-p-tolyl-5-methylthiazolidine, m. p. 72—73°, and its *picrate*, n. p. 164—166°; 2-p-bromophenylimino-3-p-tolyl-5-methylthiazolidine, m. p. 81°, and 2-p-tolylimino-3-p-tolyl-5-methylthiazolidine, an oil, and its *picrate*, m. p. 140°.

Arylaminoethanols were also found to unite with arylthiocarbamides and arylcarbimides, and the resulting thiocarbamides and carbamides either by the action of heat alone or under the influence of halogen acids lost water and formed thiazolidines and oxazolidines of known structure. New compounds thus prepared are 2-o-tolylimino-3-phenylthiazolidine, m. p. 94°; 2-p-tolylimino-3-phenylthiazolidine, m. p. 113°; 2-phenylimino-3-o-tolylthiazolidine, m. p. 92°; and 2-phenylimino-3-phenyloxazolidine, m. p. 124°. In a similar manner, the arylaminopropanols gave thiocarbamides, which, under the influence of acids, condensed to a six-membered thiazan ring. The arylpropanols were obtained by heating trimethylene chlorohydrin with the amine for several hours at 130°. Thus *p*-tolylamine gave *p*-tolyl- $\gamma$ -hydroxypropylamine. Thiocarbamides and thiazans thus prepared are  $\alpha\beta$ -diphenyl- $\alpha$ -propanolthiocarbamide, m. p. 130°; 2-phenylimino-3-phenylthiazan, m. p. 139°;  $\alpha\beta$ -di-p-tolyl- $\alpha$ -propanolthiocarbamide, m. p. 142°; 2-p-tolylimino-3-p-tolylthiazan, m. p. 111°;  $\beta$ -phenyl- $\alpha$ -p-tolyl- $\alpha$ -propanolthiocarbamide, m. p. 146°;  $\alpha$ -phenyl- $\beta$ -p-tolyl- $\alpha$ -propanolthiocarbamide, m. p. 127°; 2-phenylimino-3-p-tolylthiazan, m. p. 139°, and 2-p-tolylimino-3-phenylthiazan, m. p. 94°.

$\gamma$ -Chloro- $\alpha$ -arylamino- $\beta$ -hydroxypropanes combined with thiocarbimides to give thiocarbamides, which could not be isolated, owing to loss of hydrogen chloride and the consequent closure of the thiazan ring with the production of 5-hydroxythiazans, of which the following are described. 2-Phenylimino-5-hydroxy-3-p-tolylthiazan, m. p. 175°; 2-p-tolylimino-5-hydroxy-3-p-tolylthiazan, m. p. 142°, and its *hydrochloride*, m. p. 204°, and *picrate*, n. p. 195°; 2-phenylimino-5-hydroxy-3-*p*-anisylthiazan, m. p. 157°, and its *picrate*, m. p. 135°; 2-phenylimino-5-hydroxy-3-*p*-chlorophenylthiazan, m. p. 171°; 2-phenylimino-5-hydroxy-3-phenylthiazan, n. p. 175°, and its *picrate*, m. p. 150°, and *phenylurethane* derivative, m. p. 185°.

W. G.

**Isonitriles. IV. Reaction with Organic Acids.** M. PASERINI (*Gazzetta*, 1922, 52, ii, 250—257; cf. A., 1921, i, 743, 895; 1922, i, 731).—At the ordinary temperature, aromatic isonitriles [carbalamines] react with certain organic acids yielding carbon monoxide and salts of substituted formamides. Thus, with benzoic,

mandelic, lactic, and salicylic acids, phenylcarbylamine gives salts of diphenylformamidine composed of two mols. of the acid and one mol. of the base. Acetic acid, however, yields, not diphenylformamidine, but a syrupy liquid probably containing formanilide and possibly also acetanilide. From *p*-carbylaminoazobenzene and lactic acid, the acid lactate of 4:4'-bisazobenzeneformamidine is obtained, together with formyl-*p*-aminoazobenzene. The arylformamidine salts formed in these reactions are accompanied by oily compounds which yield aniline and alkali formates when heated with alkali hydroxide and are probably formanilides. According to Nef (A., 1892, 1438), the action of hydrogen chloride on phenylcarbylamine in anhydrous ethereal solution yields the additive compound  $(NPh\cdot CHCl)_2\cdot HCl$ . The formation of this compound is not detectable, although it may occur as an intermediate stage, in the action of hydrogen chloride and acetone or methyl ethyl ketone on phenylcarbylamine or *p*-carbylaminoazobenzene, the only products observed being the monohydrochlorides of the corresponding arylformamidines. Thus, hydrochloric acid in presence of ketones acts like organic acid in absence of ketones or aldehydes.

*Diphenylformamidine acid mandelate*,

crystallises in colourless needles, m. p. 126°, and, when suspended in water, yields part of its acid to the latter. The *acid lactate*,  $C_{13}H_{12}N_2\cdot 2C_3H_5O_3$ , forms long, colourless needles, m. p. 136°, and when treated with water, yields the *normal lactate*, which crystallises in colourless needles, m. p. 151°. *Diphenylformamidine salicylate* crystallises in large plates, m. p. 165°, softening at 160°, and the *benzoate* in colourless needles, m. p. 175–176°.

4:4'-*Bisazobenzeneformamidine acid lactate*,  $C_{25}H_{20}N_6\cdot 2C_3H_5O_3$ , crystallises in flat, orange needles, m. p. 153°, and the *free base*,  $C_{25}H_{20}N_6$ , in lustrous, orange needles, m. p. 196–197°.

Diphenylformamidine picrate,  $C_{13}H_{12}N_2\cdot C_6H_3O_7N_3$ , is formed by the action of picric acid on phenylcarbylamine. T. H. P.

**The Additive Formation of Four-membered Rings. I. The Synthesis and Division of Derivatives from 1:3-Dimethindiazidine.** CHRISTOPHER KELK INGOLD and HENRY ALFRED PIGGOTT (T., 1922, 121, 2793–2804).

**Barbituric Acid.** WALTER BOCK (Ber., 1922, 55, [B], 3400–3405).—An aqueous solution of barbituric acid gives a bright yellowish-red coloration with a piece of wood. The reaction is shown distinctly at a dilution of 1 in 1000; it is not disturbed by the presence of free mineral acids. Barbituric acids, substituted in position 5, do not appear to give the reaction.

5-Bromobarbituric acid, decomp. 212–215° after previous softening, can be prepared directly from the parent acid dissolved in water and bromine (four-fifths molecular proportion) at 50–60°. It is transformed by further treatment with bromine into 5:5-dibromobarbituric acid, prisms, decomp. 220–221°, or leaflets, decomp. 235–237°, which appear to be chemically identical. The

prismatic form is also obtained by the action of bromine on benzylidenebarbituric acid. Whereas the salts of monobromobarbituric acid are stable towards water, the free acid is readily decomposed, yielding mainly hydurilic acid; barbituric acid is also produced, but the presence of parabanic acid could not be established with certainty. 5:5-Dibromobarbituric acid is not greatly affected by a short treatment with boiling water, but by longer action is converted into alloxan and ultimately into hydurilic and barbituric acids; since the latter may be regarded as reduction products of alloxan it appears that other substances arising from the simultaneous oxidation of another part of the latter must also be present.

Aqueous solutions of barbituric acid and *p*-benzoquinone give an intense dark red colour which is perceptible at a dilution of 1 in 10,000. When equivalent proportions of the components are used, a definite product cannot be isolated and the colour disappears after short boiling. When, however, the acid and benzoquinone are taken in the molecular proportion 1:2, a tribasic acid,  $C_{26}H_{20}O_{15}N_4$ , an amorphous, black powder which decomposes without melting when heated, is obtained (the barium salt was analysed). The quinone appears to act to some extent as an oxidising agent.

H. W.

**Nitroso-2-hydroxyindazole.** E. BAMBERGER (*Ber.*, 1922, 55, [B], 3371—3375).—In a previous communication, Bamberger and Demuth (*A.*, 1902, i, 650) have shown that 2-hydroxyindazole is obtained by the action of alkali hydroxide on *o*-azidobenzaldoxime, and is converted by nitrous acid into a nitroso-derivative. The latter compound is now proved to be 3-nitroso-2-hydroxyindazole,  $C_6H_4 \begin{smallmatrix} \text{N} \\ \text{C}(\text{NO}) \end{smallmatrix} \text{N-OH}$  or  $C_6H_4 \begin{smallmatrix} \text{N} \\ \text{C}(\text{NO}) \end{smallmatrix} \text{N-OH}$ , since it is converted by reduction with tin foil in the presence of glacial acetic acid into 3-aminoindazole, m. p. 153—154°.

Preliminary experiments appear to show that *o*-hydroxylaminobenzaldoxime is not transformed into 2-hydroxyindazole by the action of alcoholic potash at the atmospheric temperature.

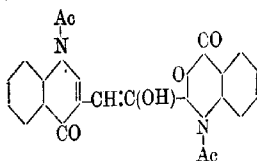

H. W.

**Catalytic Reduction of Indigotin.** ANDRÉ BROCHET (*Rev. Gen. Mat. Col.*, 1922, 27, 131—136).—Indigotin is rapidly reduced to indigo-white by hydrogenation even at atmospheric pressures, in presence of a reduced nickel catalyst, particularly at slightly elevated temperatures, as, for example, 50—60°, and in presence of sodium hydroxide. The catalyst is added to a suspension of about twice its weight of indigotin in dilute sodium hydroxide solution, and the gas is either bubbled through the liquid with vigorous agitation, or the liquid may be shaken in an atmosphere of the gas. Reduction is complete in one half to one hour, and the nickel recovered from the bleached indigo solution by filtration may be used repeatedly for subsequent hydrogenations. The catalyst retains its activity unimpaired for long periods. Other vat dyes such as "thioindigo," indanthrene, etc., and also certain

dyes which are not reoxidised by air, such as malachite-green, can in a similar way be converted into their leuco-compounds.

G. F. M.

**The Action of Acetic Anhydride on some Furfurylidene-anthranilic Acids.** JOHN B. EKELEY and EMMET C. ROGERS (*J. Amer. Chem. Soc.*, 1922, **44**, 2655—2657).—Furfurylideneanthranilic acid, m. p. 151° (decomp.) when heated in xylene with excess of acetic anhydride, gave as a final product a compound, m. p. 208°, which is probably the enol form of 1-keto-4-acetyl-3(4': keto-1'-acetyldihydro-2-quinolylacetyl)-dihydro-2:4-benzoxazine (annexed formula). It is probable

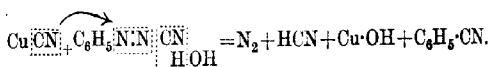

that in the first stage of the reaction a furfuryloxazine is formed but suffers a partial decomposition by the acetic acid set free in the reaction, and that the acetyl-anthranilic acid thus formed reacts with the undecomposed oxazine and the resulting carbon chain suffers condensation with the carboxyl group of the substituted anthranilic acid to give the quinoline derivative.

2-Bromo-5-furfurylideneanthranilic acid, prepared from 2-bromo-methyl-5-formylfuran and anthranilic acid, does not give the above complex reactions with acetic anhydride.

W. G.

**Interaction of Diazonium Salts and Phenols.** FREDERICK DANIEL CHATTAWAY and HENRY ROWLAND HILL (*T.*, 1922, **121**, 2756—2760).

**An Explanation of Sandmeyer's Reaction.** IVO FRANZ KEME (*Chem. Ztg.*, 1922, **46**, 1042).—The replacement of the diazo-group by chlorine, bromine, or cyanogen in the presence of the cuprous salt is explained by supposing that the cyanogen or halogen attached to the copper atom is the one which enters the benzene ring:

This view is supported by the fact that a cuprous salt which contains the group or atom which it is desired to introduce into the benzene ring must always be present.

H. C. R.

**Researches on Residual Affinity and Co-ordination. XIII. Cobaltammine and Chromic Lakes of the Azo-salicylic Acids.** GILBERT T. MORGAN and J. D. MAIN SMITH (*T.*, 1922, **121**, 2866—2874).

**Vat Dyes of the Azo-series.** DHIRENDRA NATH MUKERJI (*T.*, 1922, **121**, 2879—2882).

**Certain Triphenylmethane Dyes.** WALTER A. JACOBS and MICHAEL HEIDELBERGER (*J. Amer. Chem. Soc.*, 1922, **44**, 2626—2628).—Certain dyes of the malachite-green series have been pre-

pared with a view to study their bactericidal action. The dyes were prepared in the usual way by the oxidation of the leuco-compounds with lead peroxide, and the leuco-compounds were prepared either from the corresponding aldehyde and dialkylaniline or from benzhydrol and the substituted aniline. In a number of cases where the chloride and sulphate proved too soluble for convenient manipulation, the nitrate, being less soluble, was prepared. Malachite-green and brilliant-green may be readily isolated and purified in this form. The following derivatives of leucomalachite-green are described: *m*-Acetylamido-, m. p. 154·5–155·5°; *m*-carb-amido-, m. p. 194–196°; *p*-diethylamino-, m. p. 142–144·5°; *o*-chloro-*p*-dimethylamino-, m. p. 170–171·5°; 2-hydroxy-5-benzene-azo-, m. p. 186–187°, and 2-hydroxy-5-*p*-methoxybenzeneazo-, m. p. 187–188°. The derivatives of malachite-green in the form of the following salts were prepared: *p*-Methyl- as its chloride, m. p. 160°; *o*-chloro- as its chloride, m. p. 170°; *p*-chloro- as its nitrate, m. p. 120–175°; *p*-nitro- as its chloride, m. p. 150–155°; *p*-acetyl-methylamido- as its nitrate, m. p. 193–196°; *o*-chloro-*p*-dimethyl-amino- as its chloride, m. p. 185–190°; *m*-carb-amido- as its nitrate, m. p. 185°; *o*-hydroxy- as its chloride, m. p. 195°; *p*-hydroxy- as its chloride, m. p. 185–190°; *o*-methoxy- as its nitrate; *m*-methoxy- as its carbinol, m. p. 147–149·5°; *p*-methoxy- as its chloride, m. p. 125–140°; *o*-ethoxy- as its carbinol, m. p. 178–180°; *p*-ethoxy- as its chloride, m. p. 150°; 3:4-methylenedioxy- as its chloride, m. p. 155–160°; the anhydride from the *o*-hydroxy-acetic acid, m. p. 170–175°; furyl- as its nitrate, m. p. 190°. The m. p. of the salts as given above are also decomposition points.

W. G.

**The Diazo-reaction in the Carbazole Series.** Carbazole-3-diazoimine and -3-diazonium Salts. GILBERT T. MORGAN and HUGH NORMAN READ (T., 1922, 121, 2709–2717).

**Electrolytic Preparation of Phenylhydrazine.** HIDEO WACHI (Japan Pat. 40194).—Pure phenylhydrazine can be prepared from sodium diazobenzenesulphonate by electrolytic reduction in the presence of sodium hydrogen sulphite. Aniline 25 g., and sodium carbonate 20 g., are dissolved in water 300 g., and sulphur dioxide is passed into the liquid until the solution becomes clear. It is then added, drop by drop, to the calculated quantity of sodium nitrite previously neutralised with acetic acid, to which 30 c.c. of saturated sodium hydrogen sulphite solution has been added. The solution is electrolysed, using spongy zinc or tin rods as electrodes, the operation being conducted at 30–35° during three hours, using a current of 7 volts and a current density 5 amperes per sq. dm. On concentrating the solution and then adding hydrochloric acid to it, phenylhydrazine hydrochloride separates.

K. K.

**Action of Ultra-violet Light on Egg-albumin in Relation to the Isoelectric Point.** JANET H. CLARK (*Amer. J. Hyg.*, 92, 2, 322–324; cf. *Amer. J. Physiol.*, 1922, 61, 72).—With solutions of egg-albumin of  $P_H > 4.8$ , ultra-violet light causes

aggregation and flocculation; otherwise an increase in dispersion results. Changes in charge are accompanied by change in chemical properties. As the  $p_H$  becomes less than 4.8, the precipitation on half-saturation with ammonium sulphate increases. Positively, but not negatively, charged particles of albumin are precipitated by sulphate-ions.

CHEMICAL ABSTRACTS.

**The Reduction of Methæmoglobin by Ammonium Sulphide.**

G. QUAGLIARIELLO (*Arch. di Scien. Biol.*, 1922, 3, 308—312; from *Physiol. Abstr.*, 1922, 7, 400).—Ammonium sulphide reduces methæmoglobin slowly in the cold, rapidly on warming, but without the formation of intermediate products. Oxyhæmoglobin is formed after reduction has taken place if the solution is shaken.

W. O. K.

**Hæmocyanin. III. The Absorption of Light by Oxyhæmocyanin.**

G. QUAGLIARIELLO (*Publ. St. Zool. Napoli. Ric. fisiol. chim. biol.*, 1922, 1, 57; from *Physiol. Abstr.*, 1922, 7, 405—406; cf. A., 1921, i, 467).—Oxyhæmocyanin from molluscs and arthropods shows one band in the yellow and the beginning of another in the blue. The former band is due to the copper contained in an atomic form in oxyhæmocyanin, and corresponds with  $\lambda$  579  $\mu\mu$  in molluscs and  $\lambda$  563  $\mu\mu$  in arthropods. The second band corresponds with  $\lambda$  475  $\mu\mu$  in both types, and with the second band observed by Dhéré in the ultra-violet. Reduced hæmocyanin does not show any absorption band. Oxyhæmocyanin does not form with potassium ferricyanide any compound analogous to methæmoglobin.

W. O. K.

**The Classification of the Nucleic Acids and the Place of Guanylnucleic Acid in the System.**

R. FEULGEN (*Z. physiol. Chem.*, 1922, 123, 197—204).—A general review of the nucleic acids and of their nomenclature and classification.

W. O. K.

**Guanylnucleic Acid.** R. FEULGEN (*Z. physiol. Chem.*, 1922, 123, 145—158).—In the guanylnucleic acid described by the author (A., 1921, i, 76) and by Hammarsten (*ibid.*, 200), there appears to be a nucleic acid of the type of thymus-nucleic acid in organic combination. There may also be nucleotides containing a pentose.

W. O. K.

**The Isoelectric Condition of Gelatin.** SIDNEY OWEN RAWLING and WALTER CLARK (*T.*, 1922, 121, 2830—2843).

**The Two Forms of Gelatin and their Isoelectric Points.**

JOHN ARTHUR WILSON and ERWIN J. KERN (*J. Amer. Chem. Soc.*, 1922, 44, 2633—2636).—Gelatin, like collagen, shows two minimum points of swelling with change of hydrogen-ion concentration, one at  $P_H$  4.7 and the other at 7.7. These results accord with those of Loeb (A., 1918, i, 317, 318) and those of Davis and Oakes (A., 1922, i, 63) and it is suggested that the two minima represent the isoelectric points of the gel and sol forms of gelatin, respectively.

W. G.

**Keratin.** II. A. HEIDUSCHKA and E. KOMM (*Z. physiol. Chem.*, 1922, **124**, 37—64; cf. A., 1922, i, 967).—The products obtained by the partial hydrolysis of keratin have been investigated with respect to precipitation by ammonium sulphate and by zinc sulphate, and the limits of precipitation of the various fractions found.  
W. O. K.

**Mechanism of the Influence of Acids and Alkalis on the Digestion of Proteins by Pepsin or Trypsin.** JOHN H. NORTHROP (*J. Gen. Physiol.*, 1922, **5**, 263—274).—The rate of digestion of various proteins by pepsin or trypsin depends on the amount of ionised protein present, being a minimum at the isoelectric point and a maximum at that hydrogen-ion concentration at which the protein is completely combined with acid or alkali to form a salt, and it does not depend on the physical properties of the protein solution.  
W. O. K.

**Invertase.** IV. R. WILLSTÄTTER and W. WASSERMANN (*Z. physiol. Chem.*, 1922, **123**, 181—196).—The invertase of autolysed yeast is much better adsorbed by aluminium or kaolin if the solution containing it is first well diluted. The same holds for precipitation by lead acetate. The facts are applied to the preparation of purified invertase.  
W. O. K.

**Additive Reactions of the Phosphorus Haloids.** V. **The Formation of an Unsaturated Phosphinic Acid.** JAMES B. CONANT and BERNARD B. COYNE (*J. Amer. Chem. Soc.*, 1922, **44**, 2530—2536; cf. A., 1920, i, 454; 1921, i, 69).—The mechanism of the formation of an unsaturated phosphinic acid previously isolated (*loc. cit.*) from acetophenone, phosphorus trichloride, and acetic acid has been established by a study of the corresponding hydroxy- and chloro-phosphinic acids. It is shown that the hydroxy-phosphinic acid which is probably first formed is very readily converted into the chloro-acid by the action of hydrochloric acid, and that the chloro-acid in turn loses hydrogen chloride, giving the unsaturated acid. When acetophenone, phosphorus trichloride, and glacial acetic acid are mixed and the mixture is saturated the next day with dry hydrogen chloride,  $\alpha$ -chloro- $\alpha$ -phenylethylphosphinic acid, m. p. 174—175°, is obtained and is readily hydrolysed by water at the room temperature to the hydroxy-acid. When heated above its melting point or more slowly when boiled in aqueous solution, the chloro-acid is converted into  $\alpha$ -phenylvinylphosphinic acid (*loc. cit.*). This unsaturated acid on bromination yields  $\alpha\beta$ -dibromo- $\alpha$ -phenylethylphosphinic acid, m. p. 186—188°, which when heated above its melting point loses hydrogen bromide, giving  $\beta$ -bromo- $\alpha$ -phenylvinylphosphinic acid, m. p. 133—135°. This acid when treated with aqueous sodium carbonate gives phenylacetylene, and in a similar manner the dibromo-acid gives  $\alpha$ -bromostyrene. By the action of water alone, the dibromo-acid is converted into  $\alpha\beta$ -dihydroxy- $\alpha$ -phenylethylphosphinic acid, m. p. 143—145°. Phenylvinylphosphinic acid when heated with hydrobromic acid in a sealed tube at 100° for seventeen hours gives

$\beta$ -bromo- $\alpha$ -phenylethylphosphinic acid. By the action of chlorine, the unsaturated acid gives  $\alpha\beta$ -dichloro- $\alpha$ -phenylethylphosphinic acid, m. p. 175–178°. W. G.

**Organic Arsenic Compounds.** [Derivatives of Phenylarsinic Acid.] A. ALBERT (U.S. Pat. 1425929, 1425930, and 1425931).—*p*-Acetylphenylarsinic acid (darkens above 340° without melting) is obtained by dissolving the hydrazone in dilute sodium carbonate solution, adding hydrazine hydrate, and after some time hydrochloric acid. The phenylhydrazone, yellow plates, decomposes above 225°. 4-Hydroxy-3-propionylphenylarsinic acid *p*-nitrophenylhydrazone, yellow needles, decomposes above 235°. The semicarbazone (?) of 3-nitro-1-hydroxyacetylphenylarsinic acid becomes brown above 240°. *p*-Aminoguanidinoacetylphenylarsinic acid decomposes above 300°. *p*-(Acetylvinyl)phenylarsinic acid semicarbazone, thick needles, becomes brown above 330°. *p*-Formylphenylarsinic acid diethylhydrazone decomposes above 140°; the phenylmethylhydrazone, feathery needles, has m. p. 295° (decomp.). Semicarbazide and 3-hydroxy-4-acetylphenylarsinic acid yield a light yellow product. Carbonylhydrazide and *p*-benzoylphenylarsinic acid yield a white, crystalline compound, almost unchanged at 360°. Similar compounds are obtained from malonylhydrazide and oxalylhydrazide.

Treatment with sodium hyposulphite, phosphorous acid, phosphorus trichloride, hydrogen iodide, sulphur dioxide, or sodium hydrogen sulphite effects selective reduction of the arsenic yielding derivatives of trivalent arsenic, or of arsenobenzene.

#### CHEMICAL ABSTRACTS.

**The Preparation of Sulpharsphenamine.** CARL VOEGTLIN and J. M. JOHNSON (*J. Amer. Chem. Soc.*, 1922, **44**, 2573–2577).—The new compound, designated as *sulpharsphenamine*, was not obtained in the pure state. It is prepared from *arsphenamine* (1 mol.), formaldehyde (2 mols.), and sodium hydrogen sulphite (4 mols.). In its preparation, the following conditions must be observed. The solution of *arsphenamine* must be complete before the formaldehyde is added; about sixty seconds must be allowed for the formaldehyde to act before the addition of the sulphite, which should be freshly prepared from sodium carbonate and sulphur dioxide and should be added in two portions with an interval of seven minutes between the additions. The *sulpharsphenamine* is best precipitated by pouring the solution in a fine stream into five volumes of 95% alcohol and is dried by washing with absolute alcohol. It gives its free acid on decomposition with glacial acetic acid. The presence of the side chain  $\text{NH}\cdot\text{CH}_2\cdot\text{O}\cdot\text{SO}_2\text{Na}$  as distinct from the side chain  $\text{NH}\cdot\text{CH}_2\cdot\text{O}\cdot\text{SONa}$  as present in *nearsphenamine* is shown by its behaviour towards the indigocarmine test of Reinking, Dehnell, and Labhardt (cf. A., 1905, i, 261). W. G.

**Examination of Nearsphenamine [Neosalvarsan].** \*II. The Constitution of the French Drugs. A. DOUGLAS MACALLUM (*J. Amer. Chem. Soc.*, 1922, **44**, 2578–2582).—Using the technique

previously described (A., 1921, ii, 420), the author has examined a number of samples of French neosalvarsan. He finds rather more variation in these samples than in American products. The most noticeable physical characteristic of the French compounds is that, unlike the neosalvarsans, which are soluble in neutral and alkaline solution alone, they dissolve unchanged in weakly acid media as well. The French compounds darken and decompose at relatively higher temperatures, are less affected by atmospheric oxygen, and are of lower toxicity and also of lower trypanocidal activity than the American preparations. Details of analyses are given.

W. G.

**An Arsenical Glucoside: Diglucosidodiaminodihydroxyarsenobenzene.** A. AUBRY and E. DORMOY (*Compt. rend.*, 1922, 175, 819—822; cf. Sokorin, A., 1888, 807; Marchlewski, A., 1894, i, 104, 511; Irvine and Moodie, T., 1908, 93, 95; Irvine and Gilmour, T., 1908, 93, 1429).—Diaminodihydroxyarsenobenzene combines with dextrose, yielding a pale yellow, crystalline powder which was shown to be diglucosidodiaminohydroxyarsenobenzene. The substance is readily soluble in water, the solution being laevorotatory,  $[\alpha]_D -560^\circ$ . When kept, it is slowly hydrolysed; after twenty days less than 40% remains unchanged. The hydrolysis may be retarded by addition of dextrose. A monoglucoside is formed as an intermediate hydrolysis product. In a discussion of the constitution, the authors point out that the glucose may be linked to the amino- or to the phenolic groups; the reactions of the substance indicate the former position.

H. J. E.

### Physiological Chemistry.

**The Comparative Concentrations of Alcohol in Human Blood and Urine at Intervals after Digestion,** WALTER R. MILES (*J. Pharm. Expt. Ther.*, 1922, 20, 265—319).—Estimations of the alcohol in the whole blood, plasma, and urine of men who had consumed a known quantity of alcohol show a greater concentration in the plasma than in the whole blood. At first, the concentrations in the blood and in the urine are approximately the same, but soon that of the urine becomes appreciably greater, and exceeds that of the plasma.

W. O. K.

**Factors which Determine the Concentration of Calcium and of Inorganic Phosphorus in the Blood-serum of Rats.** BENJ. KRAMER and JOHN HOWLAND (*Bull. Johns Hopkins Hosp.*, 1922, 33, 313—317).—The normal concentration of calcium in the serum of rats is from 9.5 to 10.5 mg. per 100 c.c. and that of phosphorus from 7 to 8.5 mg. per 100 c.c. These values were not increased by changes in the diet or by treatment with ultra-violet

light. By lowering the amount of calcium or phosphorus in the food sufficiently, the concentration of the same in the serum could be diminished by as much as 50%. Subsequent addition of fish-liver oils to the food brought the values back to normal. The same result could be obtained, with phosphorus, by illumination with light of wave-length less than 3000 Å. A similar effect could be obtained by starvation for a few days.

## CHEMICAL ABSTRACTS.

**Sodium Chloride and Selective Diffusion in Living Organisms.** JACQUES LOEB (*J. Gen. Physiol.*, 1922, 5, 231—254).—Sodium chloride, calcium chloride, and cerium chloride inhibit the diffusion of strong acids into the egg of *Fundulus* as shown by the decrease in the mortality among the eggs immersed in the acid on the addition of the chloride, and also by the decrease in the rate of fall of the hydrogen-ion concentration.  $M/8$  sodium chloride corresponds with  $M/1,000$  calcium chloride or  $M/30,000$  cerium chloride in producing this inhibition. Weak, undissociated acids are but feebly inhibited by these chlorides, if at all. The diffusion of strong alkalis is accelerated by sodium chloride, and more so by calcium chloride. Sodium chloride in moderate concentration accelerates also the diffusion of potassium chloride into the egg of *Fundulus*, whilst calcium chloride does not.

W. O. K.

**Dextrose in Eggs of Vertebrates.** G. GORI (*Atti R. accad. fisiocrit. Siena*, 1920, 21, 711—716; from *Chem. Zentr.*, 1922, iii, 927).—Dextrose is absent from the yolks of eggs of *Torpedo* and of fishes: the amount of urea present is insufficient to obscure the reaction. Using material dried first at 45° and then in a vacuum, dextrose was found to be absent from mammalian ova, present, combined and free, in birds' eggs, and present in the free state in amphibian eggs.

G. W. R.

**The Synthetic Formation of Kynurenic Acid in the Surviving Liver.** Z. MATSUOKA and S. TAKEMURA (*J. Biochem. [Japan]*, 1922, 1, 175—180).—Kynurenic acid is produced by the perfused liver of dogs when either tryptophan or indolepyruvic acid is added to the blood. It is suggested that indolepyruvic acid is probably an intermediate step in the transformation of tryptophan into kynurenic acid. This hypothesis is based on the fact that the same amount was produced (0.1285 and 0.1202 g.) with 1 g. of either the tryptophan or indolepyruvic acid in the perfusing mixture.

## CHEMICAL ABSTRACTS.

**Some Compounds Extracted from Human Skeletal Muscles.** R. ENGELAND and W. BIEHLER (*Z. physiol. Chem.*, 1922, 123, 290—294).—The following compounds have been isolated from human skeletal muscles; carnitine,  $C_7H_{15}O_3N$ ; neosine,  $C_8H_{17}O_2N$ ; myokynine,  $C_{11}H_{25}O_3N_2$ ; and mirgeline isolated as the *chloroaurate*,  $C_{11}H_{22}O_3N_2 \cdot HAuCl_4$ , light yellow, nodular crystals.

W. O. K.

**The Pharmacology of Cell Breathing. II. The Function of Iron in Cell Breathing. III. The Dependence of Cell Respiration on the Hydrogen-ion Concentration.** PH. ELLINGER and N. LANDSBERGER (*Z. physiol. Chem.*, 1922, 123, 246—263, 264—279).—Amino-acids are oxidised by oxygen in presence of an emulsion of zinc sulphide-copper phosphor in a gelatin solution, as they are in presence of charcoal (Warburg, A., 1921, i, 230; 1922, i, 190), or by an emulsion of broken-up goose erythrocytes. Potassium cyanide decreases the velocity of oxidation in the case of the goose cells, but at the same time it is itself oxidised. The rate of absorption of oxygen shows a minimum at a low concentration of potassium cyanide and the same phenomenon is observed in the case of isolated frog's muscle if potassium cyanide is applied. The oxidation is parallel to the fluorescence and phosphorescence of the cells under ultra-violet illumination. This is taken to indicate that the efficiency of the cells in catalysing oxidation is connected with the ability of the iron to lose an electron, and so activate the oxidisable material. The rate of consumption of oxygen with charcoal or with cells depends on the hydrogen-ion concentration, and this effect seems to be exerted primarily on the amino-acid which is being oxidised. W. O. K.

**The Presence of Aldol in the Urine of Diabetics.** ROBERT FRICKE (*Z. physiol. Chem.*, 1922, 124, 1—7).—Aldol in the urine of diabetics is only partly detected by the "dimedon" method previously employed (A., 1922, i, 300; ii, 326). Improvements are described which render the method more sensitive and accurate. W. O. K.

**The Sugar Content of Cerebrospinal Fluids.** K. MIFUJI (*J. Tokyo Med. Soc.*, 1921, 35, No. 10; *Japan Med. World*, 2, 78).—The normal sugar content of the spinal fluid of the Japanese averages 0.052%. The factor obtained by dividing the blood-sugar content by the spinal fluid sugar content is largest in children and least in the senile cases. In the atrophic form of beri beri the sugar content of both liquids is practically the same as normal, but in the oedematous form they are both increased. In epidemic cerebrospinal meningitis the blood-sugar content is as high as the maximum normal (0.114%) but that of the spinal fluid is remarkably decreased. In epilepsy the spinal fluid sugar content in the intermissions of an attack was low, 0.021%, but returned to normal eighteen hours after the attack. CHEMICAL ABSTRACTS.

**Pharmacology and Therapeutics of Iodides.** E. D. OSBORNE (*J. Amer. Med. Assoc.*, 1922, 79, 615—617; from *Physiol. Abstr.*, 1922, 7, 453).—After the administration of sodium iodide by the mouth, there is an increase in the concentration of sodium in the blood, whilst only a trace of iodine was found in the serum proteins when these were precipitated by tungstic acid or alcohol. On the other hand, after oral administration of potassium iodide, there is no increase of potassium in the blood, but an increase of sodium, whilst 7 to 26% of the iodine given was found in the serum proteins. W. O. K.

**Urea.** A. MARIE (*Compt. rend. Soc. Biol.*, 1922, **86**, 998; cf. *ibid.*, 1922, **86**, 72).—Intravenous injections of adrenaline hydrochloride produce a considerable increase in the urea content both of the blood and of the parenchyma of the liver freed completely from blood. Adrenaline has also been found to suppress the decomposition of urea in vitro when added to a soja bean extract. Although the vegetable urease may be entirely unlike the hepatic urease, the test-tube experiments lead to the conclusion that the increase in urea content observed after an injection of adrenaline is likewise due to a suppression of the hydrolysis of urea.

CHEMICAL ABSTRACTS.

**The Separation of Ethereal Sulphates in Rabbits after Administration of Phenol, *p*-Bromophenol, and Bromobenzene.** H. RHODE (*Z. physiol. Chem.*, 1922, **124**, 15–36).—If phenol is administered to rabbits (0.2 g. per kg.), 12% is eliminated in the urine as the ethereal sulphate, whereas if cystine, taurine, or sodium sulphite is administered at the same time, 33%, 17%, and 27%, respectively, of the phenol is eliminated. Thiosulphate and sulphate are without influence on the elimination of the phenol. In the cases of *p*-bromophenol and of bromobenzene, the effect of the simultaneous administration of cystine is to decrease the output of ethereal sulphates, the explanation apparently being that phenylmercapturic acid is formed in both cases. This indicates that the bromobenzene in the animal organism is first of all oxidised to *p*-bromophenol.

W. O. K.

**Pharmacology of Benzyl Compounds. II.** CARL NIELSEN and JOHN A. HIGGINS (*J. Lab. Clin. Med.*, 1922, **7**, 579–588; cf. *ibid.*, 1921, **6**, 388).—The observations suggest that the relaxing power of benzyl esters on the smooth muscle fibres of the intestine as a rule is dependent on the benzyl content and on the rate of hydrolysis of the benzyl compound.

CHEMICAL ABSTRACTS.

## Chemistry of Vegetable Physiology and Agriculture.

**The Relation of the Reaction and of Salt Content of the Medium to Nitrifying Bacteria.** CAROLYN S. MEEK and CHARLES B. LIPMAN (*J. Gen. Physiol.*, 1922, **5**, 195–204).—Nitrifying bacteria are particularly resistant to hydroxyl-ions, surviving in a medium of  $P_H$  13 and yielding their characteristic products in a medium of  $P_H$  11. Sodium sulphate is not nearly so toxic to these products as sodium chloride or sodium carbonate.

W. O. K.

**Nitrification. IV. The Carbon and Nitrogen Relations of the Nitrite Ferment.** AUGUSTO BONAZZI (*J. Bact.*, 1921, **6**, 479–499).—A study of the functions of autotrophic carbon assimilation and nitrogen nutrition of the nitroso-ferment. These functions are

intimately connected and mutually interdependent, the bacterial cell being able to assimilate the abundant stores of nitrogen in a nutritive solution in the absence of free carbon dioxide, even although a carbonate as such be present in the medium. Consequently the process of nitrogen oxidation which follows the absorption and leads to the formation of nitrous acid and its salts is dependent on the presence of this free carbon dioxide.

## CHEMICAL ABSTRACTS.

**Ergosterol in Yeast.** A. WINDAUS and W. GROSSKOPF (*Z. physiol. Chem.*, 1922, **124**, 8—14).—Ergosterol is extracted from yeast in a yield of about 0.15% and purified as ergosteryl acetate, m. p. 180—181°. On reduction with palladium black and hydrogen, this acetate unites with six hydrogen atoms to form *ergostanyl acetate*,  $C_{28}H_{50}O_2$ , small, white needles, m. p. 103°, which on hydrolysis yields *ergostanol*,  $C_{27}H_{48}O$ , fine leaflets, m. p. 129°. By treatment of ergostanol with phosphorus pentachloride, and subsequent reduction with sodium in amyl alcohol, the hydrocarbon, *ergostane*,  $C_{27}H_{48}$ , white leaflets, m. p. 72—73°,  $[\alpha]_D^{20} + 24.5^\circ$ , is obtained, which is not identical with sitosane,  $\psi$ -cholestane (coprostane), or cholestane. Ergostanol, on oxidation with chromic anhydride, yields *ergostanone*, fine white needles, m. p. 56—57°. W. O. K.

**Comparison of  $\alpha$ - and  $\beta$ -Glucose in Fermentation.** RICHARD WILLSTÄTTER and HARRY SOBOTKA (*Z. physiol. Chem.*, 1922, **123**, 164—169).—No difference can be detected in the rate of fermentation of  $\alpha$ - and  $\beta$ -glucose. This cannot be due to an equilibrium between the two forms being set up quickly, as the rate of this change under the conditions of the experiment is much slower than the rate of fermentation. W. O. K.

**The Selective Fermentation of Mixtures of Sugars.** RICHARD WILLSTÄTTER and HARRY SOBOTKA (*Z. physiol. Chem.*, 1922, **123**, 170—175).—Although glucose, fructose, and a mixture of these are all fermented by yeast with approximately the same velocity, yet on fermenting a mixture the glucose ferments more quickly than the fructose. This is apparently because the glucose is more active in the initial stages of fermentation whilst the final stages of the reaction are the same for both sugars. These final stages, however, are the slowest and so they decide the rate of the reaction as a whole. The same holds for the fermentation of a mixture of the  $\alpha$ - and  $\beta$ -forms of glucose (see preceding abstract). W. O. K.

**Selective Fermentation with Yeast Trained to Ferment Galactose.** RICHARD WILLSTÄTTER and HARRY SOBOTKA (*Z. physiol. Chem.*, 1922, **123**, 176—180).—Yeast may be trained so that it will ferment galactose more rapidly than glucose, but it is found that such a yeast will still preferentially ferment glucose out of a mixture of glucose and galactose. An explanation of this phenomenon is indicated on the lines suggested in the preceding abstract. W. O. K.

**The Influence of Copper Salts on the Yield of *Sterigmato-cystis nigra* [*Aspergillus niger*].** MARIN MOLLIARD (*Compt. rend.*, 1922, 175, 838—841).—The retarding action of solutions containing copper on the growth of *A. niger* renders direct comparison with the control solution of no value as the two may be at different stages of development. The author has compared the yield—i.e., the ratio of the weight of mycelium obtained to that of sugar consumed—in a control solution and one containing copper sulphate of a concentration of 1/3750, making allowance for the slower growth in the latter. The general result of the presence of copper is diminution of yield, but during a considerable portion of the time the reverse effect was observed. H. J. E.

**Some Aspects of Selective Absorption.** W. J. V. OSTERHOUT (*J. Gen. Physiol.*, 1922, 5, 225—230).—Analysis of the cell sap of the marine alga *Valonia* shows much more potassium and less sodium, magnesium, calcium, and sulphate-ion than exists in the surrounding sea-water, whilst the chloride is approximately constant. The organic material in the cell sap is small, and this seems to exclude the possibility of accounting for the high concentration of potassium by the assumption that it combines with some organic compound. W. O. K.

**Fixation and Polymerisation of Formaldehyde in the Dark by Green Plants. Carbon Dioxide Assimilation by Plants.** TH. SABALITSCHKA (*Z. angew. Chem.*, 1922, 35, 684—685).—Experiments with the nasturtium and the water-weed, *Elodea canadensis*, showed that these plants are capable of fixing formaldehyde and polymerising it to carbohydrates even in the absence of light. The plants were placed in an enclosed space and deprived of carbon dioxide. The sugar and starch content of the leaves was determined after some decrease had occurred below the normal by reason of the exclusion of carbon dioxide, and some of the plants were then exposed to formaldehyde either in the form of vapour or in solution in the case of the water weed, whilst others were kept for comparison. After some days the carbohydrates in the leaf were again estimated; as an example of the results, in one case 462 mg. of sugar and 1048 mg. of starch per 100 g. of leaf were found after treatment with formaldehyde, compared with 144 mg. of sugar and 495 mg. of starch in the blank experiment. The quantity of these substances in the formaldehyde experiment was actually higher than at the commencement, whereas in the control experiment the carbohydrates had continued to decrease. This shows that the plants were able to replenish their stock of carbohydrate, depleted by the absence of carbon dioxide, by making use of the formaldehyde, and that the polymerisation takes place in the absence of sunlight. Further, it provides additional evidence for the hypothesis that formaldehyde is an intermediate product of the photosynthesis of carbohydrates from carbon dioxide and water. G. F. M.

**Anthocyanin Pigments and Phlobatannins in Plants.** ST. JONESCO (*Compt. rend.*, 1922, 175, 904—907; cf. Combes, A., 1922, i, 206).—The red leaves of *Prunus Pissardii*, dried and powdered, were extracted with ethyl ether. The solution, on evaporation, yielded two separate substances: one, soluble in water and crystallising in tablets and needles, the other soluble in ethyl alcohol but not in water, and obtained as a yellow, amorphous substance on evaporation. Various reactions given by the former indicate that it is a tannin; the latter being precipitated by addition of water gives somewhat ambiguous results with aqueous reagents. It is, however, not converted into a red pigment when heated with dilute acids. Further extraction of the dried leaves with ethyl acetate and amyl alcohol yielded the anthocyanidins and pseudo-bases. The latter are readily transformed into anthocyanidins under the influence of dilute hydrochloric acid, their colour changing from yellow to red. The anthocyan constituents—i.e., the total of the pigments present in the various organs—are divided into anthocyanins, red, violet, or blue substances not extracted by amyl alcohol, anthocyanidins, red substances existing uncombined and readily soluble in amyl alcohol, and a third group of substances, the pseudo-bases, yellow in colour, which the author proposes to designate leuco-anthocyanidins. H. J. E.

**The Action of Hexamethylenetetramine on Higher Vegetation.** E. NICOLAS and G. NICOLAS (*Compt. rend.*, 1922, 175, 836—838).—Solutions of hexamethylenetetramine, the concentration of which lies between 0.1 and 0.3 g. per litre, are utilised as food by beans, but on increasing the concentration a toxic effect is produced. In the former case, the action is shown by increase in weight of the plant and by the enhanced leaf development. H. J. E.

**The Chemical Constituents of Green Plants. XXII. The Presence of Succinic Acid and of Oxalic Acid in the Currant (*Ribes rubrum*).** HARTWIG FRANZEN and FRITZ HELWERT (*Z. physiol. Chem.*, 1922, 124, 65—74; cf. A., 1922, i, 310).—By converting the acids in the filtrate from the lead acetate precipitate from the currant into their esters and subsequently into the hydrazide or the benzylidene compounds, the presence of succinic acid, malic acid, and citric acid has been demonstrated. Other acids, some unsaturated, are present in traces, including probably oxalic acid, and possibly lactic acid. W. O. K.

**Colouring Matter of the Fruit of *Gardenia florida*, L.** IETSUJI MUNESADA (*J. Pharm. Soc. Japan*, 1922, No. 486, 666—671).—The colouring matter of the fruit of *Gardenia florida*, L., from China when extracted with water (cf. Kasyer, A., 1885, 59), and decomposed with dilute hydrochloric acid in a current of carbon dioxide, yielded an amorphous powder which is identical with crocetin from saffron (cf. Decker, A., 1914, i, 979). It gave a potassium salt,  $C_{10}H_{13}O_2K$ , orange-yellow crystals, sodium salt,

short, yellowish-red needles, and ammonium salt, reddish-yellow needles.

K. K.

**Preservative Principles of Hops.** I. FRANK LEE PYMAN, HAROLD ROGERSON, and THOMAS KENNEDY WALKER (*J. Inst. Brewing*, 1922, 28, 929—934).—Attempts were made to isolate crystalline hop-bitter acids by fractional extraction with alkalis of increasing strength of an ethereal solution of the soft resins, obtained by extraction of ground hops with light petroleum. Lupulon was isolated in small yield in colourless prisms, m. p. 94.5—95.5°. No humulon was obtained by this method, and the only other crystalline compounds isolated were lactic acid,  $C_{15}H_{30}O_2$ , a saturated fatty acid previously found only in the fungus *Agaricus integer*, and small quantities of the constituents of the wax, hentriacontane, ceryl alcohol, and cerotic acid.

G. F. M.

**Nitrogenous Constituents of the Fruit of Chayote (*Sechium edule*).** KIYOHISA YOSHIMURA (*J. Biochem. [Japan]*, 1922, 1, 347—351).—The fruit of *Sechium edule* (a member of the *Cucurbitaceae*) was examined with the following results: Water 95.973% and dry substance 4.027%. The dry substance contained: crude protein 16.264%, fat 1.169%, crude fibre 7.311%, nitrogen-free extract 68.392%, ash 6.864%, total nitrogen 2.602%, protein nitrogen 1.56%, and non-protein nitrogen 1.041%; that is, of the total nitrogen 59.99% was protein and 40.009% non-protein. 20 Kg. of the fresh fruit were pressed and then extracted twice with hot water; from the extract were isolated: a small quantity of adenine and choline, 0.7 g. of arginine (as nitrate), and about 1.5 g. of guanidine (as chloroaurate).

K. K.

**The Mannan of Vegetable Ivory.** II. Hemicelluloses. HANS PRINGSHEIM and KARL SEIFERT (*Z. physiol. Chem.*, 1922, 123, 205—212; cf. A., 1912, i, 833).—Mannan, prepared from vegetable ivory shavings by the action of 5% sodium hydroxide solution, is treated with acetic anhydride containing hydrogen bromide, when it yields *mannan triacetate*,  $C_8H_7O_2(OAc)_3$ , a white, amorphous, non-hygroscopic substance,  $[\alpha]_D^{25} -27.4^\circ$  in 'acetylene tetrachloride'. Mannan, on treatment with acetic anhydride containing a small amount of concentrated sulphuric acid, yields a white, amorphous substance, from which on hydrolysis and treatment with phenylhydrazine, mannosephenylhydrazone can be obtained, besides a quantity of glucosazone and also apparently the osazone of a disaccharide.

W. O. K.

**Relation of certain Nutritive Elements to the Composition of the Oat Plant.** J. G. DICKSON (*Amer. J. Botany*, 1921, 8, 256—274).—A study of the growth and composition of *Avena sativa aristata* in relation to climate and nutrition. The content of calcium oxide is reduced proportionally to its reduction in the culture solution; it is also greatly reduced by deficiency of phosphorus or nitrogen. The extent to which the content of phos-

phorus of the grain and straw is reduced by reduction in the proportion of phosphate or potassium in the culture solution, and increased by similar reduction of calcium or nitrogen, has been determined. The content of phosphorus of both grain and straw is modified by seasonal differences except for plants grown in solutions deficient in phosphorus. The content of calcium of the grain is modified even when solutions deficient in calcium are employed, whilst that of the straw shows no consistent response to climate.

CHEMICAL ABSTRACTS.

**The Comparative Assimilability of Tricalcium Phosphate and the Phosphates of Aluminium and Iron.** CH. BRIOUX (*Compt. rend.*, 1922, 175, 1096—1099).—In soils containing little or no calcium carbonate, a considerable proportion of the phosphoric acid exists as ferric or aluminium phosphate. Experiments with six different species of plants showed that, measured by the production of dried organic matter, the use of equivalent quantities of tricalcium, ferric, and aluminium phosphates results in the highest yields being obtained in the case of aluminium and the lowest with iron, although the last-named gives results considerably above the control yield. The author points out that the usual solvents for "available phosphate" give results which are inconsistent with those of his experiments, although 1% citric acid is more trustworthy than others which have been recommended.

H. J. E.

**The Availability of Mineral Plant Food (A Modification of the Present Hypothesis).** NORMAN M. COMBER (*J. Agric. Sci.*, 1922, 12, 363—369).—The conception that plants can take up from the soil only mineral matter which is in solution is criticised. Three main objections are advanced, namely, the difficulty of correlating the composition of the soil solution with the amount of mineral matter taken up by the plant; the absence of any explanation of the intake of iron by plants, and the difficulty of explaining the availability of phosphates. A modified hypothesis is presented in which the absorption of colloids by plant roots is assumed. The possibility of a definite union of root hairs with solid mineral particles is discussed, and the subsequent dissolution of the mineral particle by the organic matter of the root hair is suggested.

A. G. P.

**Theory of Soil Acidity.** J. N. MUKHERJEE (*Nature*, 1922, 110, 732).—Experimental evidence is adduced in support of the author's view (*A.*, 1922, ii, 689) concerning the origin of soil acidity. Silica has been found to adsorb appreciable quantities of acetic, citric, hydrochloric, and nitric acids so strongly that on repeated washing the adsorbed substance cannot be removed and the aqueous extract soon becomes neutral. Treatment with aqueous potassium chloride then results, however, in the development of acidity. Simultaneous experiments on electro-osmosis indicate that the anions of the acids, and not their entire molecules, are adsorbed on the surface by chemical forces, and it is suggested that an equivalent

number of kations form a mobile second sheet of the double layer, the forces acting on these being mainly electrical in nature.

A. A. E.

**Sulphur Changes in Soil.** KURT LANTZSCH (*Intern. Mitt. Bodenk.*, 1922, 12, 22—35).—Nutrient solutions containing calcium sulphate and inoculated with soil extract showed no formation of sulphide after forty-seven days. The ratio  $\text{CaO} : \text{SO}_3$  was, however, changed slightly in some cases. Nutrient solutions to which 20 g. of soil were added to 200 c.c. and allowed to remain under anaerobic conditions for sixty days showed no appreciable formation of sulphides when titrated with iodine solution. A solution containing 0.09% of potassium sulphide together with asparagine and other nutrients developed an odour of butyric acid and lost a small amount of sulphur. A somewhat similar solution containing no organic carbon showed a production of nitrogen dioxide and ammonia when ammonium chloride was the only source of nitrogen; when sodium nitrate was used instead, nitrogen dioxide and ammonia were not produced. In each case, however, some of the sulphur was oxidised to sulphate in the inoculated solutions, whilst the control gave negative results. The control tubes were treated with 0.2 c.c. of 40% formaldehyde solution per 100 c.c. of solution.

CHEMICAL ABSTRACTS.

**The Depletion of Soils by Chemical Denudation.** MILTON WHITNEY (*Science*, 1922, 56, 216—218).—The information hitherto collected concerning the rate of chemical denudation of soil and rock material has been based mainly on the translocation of material in true solution, disregarding all matter in colloidal solution. The results have shown that the loss of silica, alumina, and iron is surprisingly small in comparison with that of potassium. It is indicated, however, that in the breaking down of silicates to a point at which potassium goes into solution, silica, alumina, and iron also go into colloidal solution in the same proportion as they bear to the potassium content in the original material. This view is supported by the fact that when finely ground silicates are brought into contact with water, soluble salts go into solution (as determined by conductivity or chemical test) and at the same time there is released a relatively large amount of colloidal material. Further investigation on these lines is necessary before it will be possible to state whether chemical erosion is a selective process which might change the chemical composition of the soil, or whether, by the materials leaving the soil in about their original ratios, there is no material change in the composition of the soil on which water has acted.

A. A. E.

## Organic Chemistry.

**The Influence of the Structure of Organic Compounds on their Sulpho-chromic Oxidation.** L. J. SIMON (*Compt. rend.*, 1922, 175, 1070—1072; cf. A., 1922, ii, 867, 868).—Among the substances which are completely oxidised by the sulpho-chromic mixture are certain straight-chain compounds, phenolic derivatives, and ring-substituted aromatic acids. In other cases, molecular structure influences the extent of oxidation, e.g., methyl benzoate is completely, whilst toluic or phenylacetic acid is only partly; oxidised. From a study of a considerable number of such examples, it is seen that this method of oxidation indicates structural differences and may be used to investigate such problems as tautomerism or intramolecular change. The author has devised a formula based on the number of carbon atoms present in the molecule and the number which escape oxidation, and regards the "oxidation deficit" which it furnishes as a first step towards a new method of structural investigation.

H. J. E.

**Oxidation of Tertiary Hydrocarbons.** P. A. LEVENE and F. A. TAYLOR (*J. Biol. Chem.*, 1922, 54, 351—362).—Further examples are given of the preparation of tertiary hydrocarbons by the malonic ester synthesis (cf. Levene and Cretcher, A., 1918, i, 250). The various stages of the syntheses are represented by the following series of compounds. Revised constants are given for certain compounds which have previously been described.

Ethyl ethylbutylmalonate [previously prepared, but not characterised, by Raper (T., 1907, 91, 1837)], b. p. 128—129°/7 mm.,  $d_4^{20}$  0.9646,  $n_D^{20}$  1.4284. Ethylbutylmalonic acid,  $C_8H_{16}O_4$ , m. p. 115°.  $\alpha$ -Ethylhexoic acid, b. p. 228—229° (Raper gave 225°); ethyl- $\alpha$ -ethylhexoate,  $C_{10}H_{20}O_2$ , b. p. 189—191°,  $d_4^{20}$  0.8628,  $n_D^{20}$  1.4128.  $\beta$ -Ethylhexyl alcohol,  $C_8H_{18}O$ , b. p. 181—183°,  $d_4^{20}$  0.8328,  $n_D^{20}$  1.4328;  $\beta$ -ethylhexyl iodide,  $C_8H_{17}I$ , b. p. 89—90°/11 mm.,  $d_4^{20}$  1.3365.  $\gamma$ -Methylheptane, b. p. 120—122° (cf. Clarke, A., 1909, i, 349),  $d_4^{20}$  0.7069,  $n_D^{20}$  1.3980.

Ethyl  $\alpha$ -methylheptylmalonate,  $C_{15}H_{28}O_4$ , b. p. 157—158°/10 mm.,  $d_4^{20}$  0.9496,  $n_D^{20}$  1.4324.  $\beta$ -Methylnononic acid,  $C_{10}H_{20}O_2$ , b. p. 147—148°/12 mm.,  $d_4^{20}$  0.9012,  $n_D^{20}$  1.4342; ethyl  $\beta$ -methylnononate,  $C_{12}H_{24}O_2$ , b. p. 115°/13 mm.,  $d_4^{20}$  0.8653,  $n_D^{20}$  1.4240.  $\gamma$ -Methylnonyl alcohol,  $C_{11}H_{22}O$ , b. p. 103—103.5°/9 mm.,  $d_4^{20}$  0.8342,  $n_D^{20}$  1.4361;  $\gamma$ -methylnonyl iodide,  $C_{10}H_{21}I$ , b. p. 115°/10 mm.,  $d_4^{20}$  1.2515.  $\gamma$ -Methylnonane,  $C_{10}H_{22}$ , b. p. 165.5—166.5°,  $d_4^{20}$  0.7354,  $n_D^{20}$  1.4126.

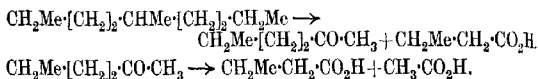

$\epsilon$ -Methylnonane ( $\beta$ -butylhexane of Levene and Cretcher, *loc. cit.*), b. p. 164—166°,  $d_4^{20}$  0.7319,  $n_D^{20}$  1.4116.

$\epsilon$ -Propylnonane,  $C_{12}H_{26}$ , b. p. 204—205°,  $d_4^{20}$  0.7559,  $n_D^{20}$  1.4228, was obtained by reduction of  $\delta$ -butyloctyl iodide (cf. Levene and Cretcher).

Ethyl butylmalonate, b. p. 122°/12 mm. (cf. Adams and Marvel, VOL. CXXIV. i.

A., 1920, i, 283),  $d_4^{20}$  0.9745,  $n_D^{20}$  1.4222. *Ethyl butylheptylmalonate*,  $C_{18}H_{34}O_4$ , b. p. 177–178°/12 mm.,  $d_4^{20}$  0.9318,  $n_D^{20}$  1.4366; *butyl heptylmalonic acid*,  $C_{14}H_{26}O_4$ , needles, m. p. 117°.  $\alpha$ -*Butylnonoic acid*,  $C_{13}H_{26}O_2$ , b. p. 179°/13 mm.,  $d_4^{20}$  0.8860,  $n_D^{20}$  1.4403; *ethyl  $\alpha$ -butylnonoate*,  $C_{15}H_{30}O_2$ , b. p. 115°/1 mm.,  $d_4^{20}$  0.8560,  $n_D^{20}$  1.4290;  $\beta$ -*Butylnonyl alcohol*,  $C_{13}H_{28}O$ , b. p. 112–114°/0.5 mm.,  $d_4^{20}$  0.8359,  $n_D^{20}$  1.4430;  $\beta$ -*butylnonyl iodide*,  $C_{13}H_{27}I$ , b. p. 121–123°/0.5 mm.  $\epsilon$ -*Methyldodecane*,  $C_{13}H_{28}$ , b. p. 225.5–227°,  $d_4^{20}$  0.7576,  $n_D^{20}$  1.4244.

When  $\epsilon$ -methylnonane was oxidised with alkaline permanganate acetic and butyric acids were identified amongst the products of the reaction; the presence of some formic acid was also detected. Apparently the oxidation proceeds mainly according to the following scheme:

E. S.

**The Formation of Hydrocarbons during the Action of Potassium on Ethyl Acetate.** HELMUTH SCHEIBLER, HEINRICH ZIEGNER, and EMIL PEPPER (*Ber.*, 1922, 55, [B], 3921–3931).—The action of potassium on an ethereal solution of ethyl acetate has been shown to lead to the formation of ethyl potassium acetate,  $\text{CH}_3\text{C}(\text{OK})\cdot\text{OEt}$  (cf. Scheibler and Voss, A., 1920, i, 366; Scheibler and Ziegner, A., 1922, i, 426). In addition, acidic substances are produced which will be described subsequently, and neutral compounds which are the subject of the present communication.

Potassium and ethyl acetate in varied proportions are allowed to react in the presence of ether and the products are decomposed either by sulphuric acid (30%) or carbon dioxide. The neutral portions are freed from admixed ester and ketones by successive treatment with concentrated potassium hydroxide solution at 80° and sodium hydrogen sulphite and are subsequently distilled, whereby a series of fractions boiling over the range 120–260° are isolated. The carbon and hydrogen content of these increases with increasing boiling point at the expense of the oxygen content. The analytical composition of the fraction b. p. 210–240°/atmospheric pressure agrees with that required by the formula  $\text{C}_{12}\text{H}_{22}$ , whereas that of the fraction b. p. above 250° harmonises with the formula  $\text{C}_{12}\text{H}_{18}$ . The constitution of the substances has not been elucidated. The insolubility of the bulk of the product in concentrated sulphuric acid indicates the absence of olefines, and the low hydrogen content makes it unlikely that paraffins are present. It is most probable that the hydrocarbons are homologues of benzene or mono- or poly-cycloparaffins.

Only traces of hydrogen are evolved in the gaseous state during the action of potassium on ethyl acetate. It appears that the liberated hydrogen reduces a portion of the ethyl potassium acetate extensively, and that in the course of the change intermediate

stances are produced which are more readily hydrogenated than ethyl potassiumacetate, a considerable proportion of which remains in the complete solution of the potassium.

The fractions boiling below  $200^{\circ}$  consist mainly of hydrocarbons, it appears to contain a certain proportion of ethers; their stability towards alkaline permanganate indicates the unsaturated nature of one or both components.

The formation of hydrocarbons is not observed when potassium is replaced by sodium under otherwise identical conditions.

H. W.

**The Chlorination of Methane.** ARTHUR SCHLEEDER and CURT JACOW (*Ber.*, 1922, 55, [B], 3710—3726).—The chlorination of methane has been studied by passing mixtures of the gases through electrically heated quartz or glass tubes. Inflammation occurs when the gases are used in molar proportions, but the flame gradually goes out; it is permanent when an excess of chlorine is employed.

On the other hand, an excess of methane is used, ignition is not observed; under these conditions chlorine is only quantitatively utilised if the temperature is not below a certain minimum depending on the precise composition and rate of flow of the mixture. The phenomena are not greatly affected by the presence of catalysts, but by an increase of temperature of  $100^{\circ}$  above the minimum. The products of the reaction are freed from hydrogen chloride by passage through warm concentrated potassium hydroxide solution. Water is unsuitable, since it dissolves appreciable amounts of methyl chloride and are subsequently condensed at a temperature not exceeding  $-110^{\circ}$ . (The vapour tensions of methyl chloride below  $-30^{\circ}$ , of methylene chloride and chloroform below  $0^{\circ}$ , and carbon tetrachloride below  $-20^{\circ}$  have been measured.) Methyl chloride can be conveniently separated from the condensate by JACOW's method of fractional distillation in a high vacuum, but the process is inapplicable to the separation of methylene chloride, chloroform, and carbon tetrachloride, which are therefore estimated approximately by the technical distillation method.

The results may be summarised as follows. When the velocity of passage of the gaseous mixture per unit of surface exceeds a certain value, and a large increase of the heating (catalysing) surface is not also provided, the reaction tends more and more towards a steady ignition, and increased formation of higher products is observed which takes place particularly at the expense of chloroform. The greater the velocity of the gas, the greater must be the catalysing surface. If the rate of flow is below the ignition value (or a suitable increase of the heating surface is provided) higher products are not formed in appreciable amount, the relative proportions of the chlorinated methanes are not those which would be expected from a step-wise reaction. When the rate of flow is below the ignition value, marked changes resulting from the production of carbon tetrachloride and higher products are observed when the catalysing surface is enormously increased (for example, by the use of activated charcoal). This result is

not appreciably modified when the minimum temperature is exceeded by as much as  $100^{\circ}$ , when the heating zone is increased or diminished, or when catalysts, such as ferric chloride, molybdenum pentachloride, or antimony pentachloride are present. On the other hand, the results obtained are not in harmony with the values calculated from Martin's formula (*Z. Elektrochem.*, 1921, 27, 150). If the rate of flow is considerably below the ignition value an increased production of chloroform and carbon tetrachloride or substances of similar boiling point at the expense of methyl and methylene chlorides is observed.

The causes which are operative in producing results differing so greatly from those of a step-wise reaction are discussed in detail. The most probable are the dissociation of methane and subsequent changes such as those represented by the equations  $\text{CH}_3\text{Cl} + \text{CH}_4 = \text{C}_2\text{H}_6 + \text{HCl}$ ,  $\text{CH}_3\text{Cl}_2 + \text{CH}_4 = \text{CH}_3\text{Cl} \cdot \text{CH}_3 + \text{HCl}$ ,  $\text{CH}_3\text{Cl} + \text{CH}_3\text{Cl} = \text{CH}_2\text{Cl} \cdot \text{CH}_3 + \text{HCl}$ , and  $\text{CH}_2\text{Cl}_2 + \text{CH}_3\text{Cl} = \text{CH}_2\text{Cl} \cdot \text{CH}_2\text{Cl}$  (or  $\text{CH}_3 \cdot \text{CHCl}_2$ ) +  $\text{HCl}$ .

The preparation of methyl chloride from methane and carbonyl chloride (cf. Hochstetter, A., 1916, i, 625) has been re-examined. The action appears to be due to greatly diluted chlorine. H. W.

**The Thallous Alkylloxides.** R. DE FORCRAND (*Compt. rend.*, 1923, 176, 20—23).—Thallous ethoxide was prepared by the method of Lamy (*Ann. Chim. Phys.*, 1863, 67, 395; 1864, 3, 373), and was isolated as an oily liquid,  $d$  3.55. It reacts with other alcohols to give the corresponding alkylloxides. In this way the author has prepared the monothallium derivatives of ethylene glycol,  $\text{OH} \cdot \text{C}_2\text{H}_4 \cdot \text{OTl}$ , and of glycerol,  $\text{C}_3\text{H}_5(\text{OH})_2 \cdot \text{OTl}$ , both of which separate as yellow solids, and thallous phenoxide, which is white and micro-crystalline. Thallous hydroxide may be similarly prepared. For the preparation of thallous acetate, the ethoxide is the best starting point, and for the neutral sulphate the hydroxide is best used.

W. G.

**The Alkylglycerols. Preparation of Alkylvinylcarbinols [Alkylallyl Alcohols].** RAYMOND DELABY (*Compt. rend.*, 1922, 175, 967—970; cf. Lespieau, A., 1911, i, 347).—Homologues of glycerol were obtained by the action of magnesium alkyl compounds on acrolein, yielding unsaturated secondary alcohols. These were brominated and the resulting bromohydrins converted into diacetins by means of potassium acetate; hydrolysis under pressure, or alcoholysis by methyl alcohol of the diacetins, then yielded the alkylglycerols. The alkylallyl alcohols obtained in the first stage have the following properties.  $\Delta^{\alpha}$ -Buten- $\gamma$ -ol (methylvinylcarbinol), b. p.  $94-96^{\circ}$ ;  $d_4^{20}$  0.854;  $d_4^{25}$  0.835;  $n_D^{20}$  1.4087 (cf. Wohl and Losanitsch, A., 1908, i, 934).  $\Delta^{\alpha}$ -Penten- $\gamma$ -ol (ethylvinylcarbinol), b. p.  $37/20$  mm.;  $d_4^{20}$  0.839;  $n_D^{20}$  1.4182 (cf. Wagner, A., 1885, 370).  $\Delta^{\alpha}$ -Hexen- $\gamma$ -ol (propylvinylcarbinol), b. p.  $133.5-134^{\circ}$ ;  $d_4^{20}$  0.851;  $d_4^{25}$  0.834;  $n_D^{20}$  1.4215.  $\Delta^{\alpha}$ -Hepten- $\gamma$ -ol (butylvinylcarbinol), b. p.  $153.5-154^{\circ}$ ;  $d_4^{20}$  0.852;  $d_4^{25}$  0.835;  $n_D^{20}$  1.4275. These alcohols yielded crystalline allophanates, m. p.  $151-152^{\circ}$ ,  $152-153^{\circ}$ ,  $139.5-140^{\circ}$ , and  $156.5-157^{\circ}$ , respectively.  $\Delta^{\alpha}$ -Hepten- $\gamma$ -ol was

resolved into its optical isomerides by Pickard and Kenyon's method (T., 1911, 99, 45).

H. J. E.

**Alkylglycerols: Transformation of Alkylvinylcarbinols into Alkylglycerols.** RAYMOND DELABY (*Compt. rend.*, 1922, 175, 1152—1154; cf. preceding abstract).—Experimental details of the transformation of brominated alkylvinylcarbinols into diacetins and of the hydrolysis of the latter into homologues of glycerol are described. *Propylglycerol*, m. p. 60—62°, b. p. 167.5—168°/14 mm., and *butylglycerol*, m. p. 52—54°, b. p. 175—175.5°/17 mm., are hygroscopic, crystalline substances; their *triacetates* have b. p. 157—159°/15 mm., and b. p. 174°/21 mm. respectively. Methylglycerol has b. p. 162.5—163.5°/15 mm. (cf. Lieben and Zeisel, A., 1881, 710); ethylglycerol has b. p. 165—166°/15 mm. (cf. Wagner, A., 1889, 231). The method gives yields corresponding with 60% of the secondary alcohol used.

H. J. E.

**Preparation of Inositol Polyphosphate.** SVIGEL POSTERNAK (Swiss Pat. 91727; from *Chem. Zentr.*, 1922, iv, 837—838; cf. A., 1921, i, 225).—A solution of inositol is heated with excess of orthophosphoric acid in the presence of sufficient excess of phosphoric oxide to combine with the water produced in esterification. The resulting products are dissolved in dilute sodium hydroxide solution and the sodium metaphosphate is changed into sodium pyrophosphate by heating at 100°. The latter salt is fractionally crystallised out from the viscous solution of the sodium salt of inositol polyphosphate. Other metallic inositol polyphosphates may be obtained from the sodium salt by double decomposition. Calcium, magnesium and ferric salts are mentioned and a crystalline calcium sodium salt having the composition

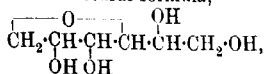

is also obtained; it probably occurs in seeds.

G. W. R.

**Cyclic Derivatives of Mannitol.** P. VAN ROMBURGH and J. H. N. VAN DER BURG (*Proc. K. Akad. Wetensch. Amsterdam*, 1923, 25, 335—340).—The unsaturated oxide,  $\text{C}_6\text{H}_8\text{O}$ , produced by heating the hexaformate of mannitol is shown to be identical with 2-vinyldihydrofuran and its structural formula,

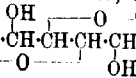

confirmed. The reduced oxide,  $\text{C}_6\text{H}_{12}\text{O}$ , prepared by reduction of  $\text{C}_6\text{H}_8\text{O}$  with hydrogen under a pressure of two atmospheres in the presence of palladium sol, is shown to be identical with 2-ethyltetrahydrofuran. The structural formula,

proposed by van Romburgh and van Maanen (*Diss. Utrecht*, 1909), for mannitan is confirmed, and that similarly proposed

for isomannide,  $\text{CH}_2-\text{CH}-\text{CH}-\text{CH}-\text{CH}_2$ , shown probably to be

correct. *iso*Mannide increases the electrical conductivity of an aqueous solution of boric acid only very slightly. The increase in the case of mannitol and mannitan, respectively, is considerable (cf. Böseken, A., 1921, i, 843). J. S. G. T.

**Investigations on the Dependence of Rotatory Power on Chemical Constitution. XIV. The Normal Aliphatic Ethers of *d*- $\beta$ -Octanol.** JOSEPH KENYON and REGINALD ARTHUR McNICOL (T., 1923, 123, 14—22).

**The Ability of  $\alpha\gamma$ -Glycols to Form Acetone [*iso*Propylidene] Compounds.** J. BÖSEKEN and P. H. HERMANS (*Ber.*, 1922, 55, [B], 3758—3760).—Trimethylene glycol unites with acetone to form an *isopropylidene* ether, a mobile liquid with a camphoraceous odour, b. p. 123—125°,  $d_{4}^{20}$  0.9587,  $n_D^{20}$  1.4252, the isolation of which is rendered difficult by the unfavourable position of the equilibrium of the reaction, glycol + acetone  $\rightleftharpoons$  *isopropylidene* + water, and by the considerable volatility of the compound with the vapours of acetone. The relatively difficult formation of an *isopropylidene* compound from trimethylene glycol is due, not only to the presence of the hydroxyl groups in the  $\alpha\gamma$ -position and the consequent necessity of forming a six- instead of a five-membered ring, but also, and chiefly, to the unfavourable steric position of these groups. Instances in which the hydroxyl groups are more favourably placed are found in anhydroenneaheptitol (Mannich and Brose, A., 1922, i, 1118) and pentaerythritol, which yields *mono*- and *di-isopropylidene* compounds, m. p. 116° and 135°, respectively.

The place of hydrogen chloride in the condensations may be taken by other acids which are soluble in acetone. Good results are obtained with  $\frac{1}{4}$ — $\frac{1}{2}$ % of concentrated sulphuric acid, which is subsequently neutralised with a considerable excess of recently-ignited, finely-divided lime. H. W.

**Preparation of an Ester of Trichloroethyl Alcohol.** FAR BENFABRIKEN VORM. FRIEDR. BAYER & CO. (D.R.-P. 358125; from *Chem. Zentr.*, 1922, iv, 888).—The alcohol is converted by the usual methods into the corresponding carbamate. For example, trichloroethyl alcohol dissolved in anhydrous ether is treated with carbamide hydrochloride, or the alcohol dissolved in benzene in the presence of quinoline is treated with carbonyl chloride, and the *trichloroethyl chloroformate* thus formed treated with ammonia. *Trichloroethyl carbamate* forms white needles, m. p. 64—65°. It is a soporific. G. W. R.

**A New Phosphoric Ester Produced by the Action of Yeast Juice on Hexoses.** ROBERT ROBISON (*Biochem. J.*, 1922, 16, 809—823).—The new ester is prepared in the following way. Lævulose or dextrose is fermented with yeast-juice and constant additions of disodium hydrogen phosphate. When the inorganic phosphate is no more utilised, barium acetate is added to the fermentation mixture, which is then neutralised and precipitated with an equal volume

of alcohol. The precipitate is then extracted with 10 parts of cold water, reprecipitated several times with basic lead acetate, purified by treatment with mercuric acetate, and finally precipitated with alcohol as the barium salt. Hexosemonophosphoric acid has  $[\alpha]_D^{25} +25.0^\circ$  in water. The metallic salts with the exception of the basic salts of the heavy metals are all readily soluble in water and are amorphous. A crystalline brucine salt was obtained. The phenylhydrazine salt of the osazone of hexosemonophosphoric acid is not identical with the isomeric compound obtained from the hexosediphosphoric acid. On hydrolysis by acids or by emulsin, the hexosemonophosphoric acid yields free phosphoric acid and a dextrorotatory substance from which glucosazone is obtained. The rotatory power of this product of degradation is, however, less than that of dextrose. S. S. Z.

**Preparation of Thiohydrins.** FARBERWERKE VORM. MEISTER, LUCIUS, & BRÜNING (Brit. Pat. 185403).—Propylene thiohydrin or mixtures of this with ethylene thiohydrin are obtained by heating propylene chlorohydrin or mixtures of this with ethylene chlorohydrin such as are obtained by the action of hypochlorous acid on olefine gas mixtures, with aqueous sodium sulphide solutions, the product being isolated by evaporating the water in a vacuum, separating the sodium chloride by pressing, and distilling the crude thiohydrin under reduced pressure. *Propylene thiohydrin* boils at  $120^\circ/4$  mm., and probably has the constitution  $S(CH_2 \cdot CHMe \cdot OH)_2$ . The thiohydrins are useful as solvents in dye printing. G. F. M.

**Varying Valency of Platinum with Respect to Mercaptanic Radicles.** SIE PRAFULLA CHANDRA RAY (T., 1923, 123, 133—141).

**Stability of Sodium Formate, Acetate, and Oxalate towards Oxidation under Pressure.** HANS SCHRADER (*Ges. Abh. Kenntnis Kohle*, 1920, 5, 193—199; from *Chem. Zentr.*, 1922, iii, 1154).—At  $160^\circ$ , no oxidation of these salts takes place in three hours. Oxidation takes place freely at  $210^\circ$  and rapidly at  $260^\circ$ . Sodium formate and sodium oxalate are oxidised equally quickly, whilst sodium acetate is more slowly attacked. The presence of sodium carbonate or sodium hydroxide has no marked effect. Intermediate stages between the three organic acids and carbon dioxide were not observed. No oxalate was formed from formate, neither was oxalate or formate formed from acetate.

G. W. R.

**Investigations on the Dependence of Rotatory Power on Chemical Constitution. XIII. The Spatial Configuration of the Unbranched Aliphatic Chain.** ROBERT HOWSON PICKARD, JOSEPH KENYON, and HAROLD HUNTER (T., 1923, 123, 1—14).

**The Anodic Preparation of Pure Lead Tetra-acetate, Tetra-propionate and Silver Diacetate.** C. SCHALL and W. MELZER (*Z. Elektrochem.*, 1922, 28, 474—477).—The specific conductivities and the corresponding temperature coefficients of solutions of

anhydrous and crystalline lead diacetate in acetic acid have been measured, and the products obtained on electrolysis of these solutions examined. When the water content of the mixture is less than 0.6%, very little change is observable at the anode, and when greater than 2%, the anodic product is mainly lead dioxide. At intermediate concentrations of water, pure lead tetra-acetate may be obtained in good yield if the apparatus is surrounded by ice. The pure salt may be prepared also from a solution of the diacetate in 99.4% acetic acid in the presence of dry sodium acetate. Small amounts of lead tetrapropionate and silver diacetate may be similarly obtained. W. E. G.

**Relationship between the Iodine Values and Refractive Indices of some Hardened Vegetable Oils.** J. J. SUDBOROUGH, H. E. WATSON, and D. Y. ATHAWALE (*J. Ind. Inst. Sci.*, 1922, 5, v, 47—69).—Samples of cotton-seed, linseed, arachis, mohua (*Bassia latifolia*), sesamé, sardine, castor, hongay (*Pongamia glabra*), and coconut oils were refined and hydrogenated at 180°, using nickel catalysts, and the relationship between iodine value and refractive index was determined. Except in the case of castor and hongay oils, the relationship between the two constants is independent of the time and of the type of catalyst used. In the case of the first six oils mentioned, the curves representing the relationship between iodine value and refractive index lie very close together and may be represented by the equation  $n_D^{20} = 1.4468 + 1.03 \times 10^{-4} (I.V.) + 7.3 \times 10^{-8} (I.V.)^2$  to an accuracy of about 0.0005. The refractive indices at 60° of the above six oils, when completely hardened, are practically identical at the value 1.4468. The refractive indices of hardened coconut oil are much lower than those of other oils with the same iodine value. In the case of castor oil, the relationship between the iodine value and the refractive index is not independent of the type of catalyst or of the time of hardening owing to the varying extent to which the hydroxyl groups are reduced. It is possible that the case of hongay oil is similar, although its acetyl value is only 24. H. C. R.

**The Catalytic Decomposition of Castor Oil.** A. MAILHE (*Compt. rend.*, 1923, 176, 37—39).—When passed over aluminium and copper turnings, castor oil undergoes decomposition, the products varying with the temperature. The products are hydrocarbons and heptaldehyde. Below 600°, the hydrocarbons formed are almost entirely homologues of methane, but above 600° aromatic hydrocarbons, such as benzene, toluene, and *m*-xylene, are also formed. W. G.

**The Transition from the Colloidal to the Crystalloidal State. Solutions of Potassium Oleate.** LOUIS LEIGHTON BIRUMSHAW (*T.*, 1923, 123, 91—97).

**Dissociation Constants of Sulphoacetic and  $\alpha$ -Sulphopropionic Acids.** H. J. BACKER (*Proc. K. Akad. Wetensch. Amsterdam*, 1923, 25, 359—363).—Values of the respective molecular conductivities at 25° of aqueous solutions of sulphoacetic acid,

mono- and di-sodium sulphoacetates, sulphopropionic acid, mono- and di-sodium sulphopropionates, propionanilide- $\alpha$ -sulphonic acid, and sodium propionanilide- $\alpha$ -sulphonate, in dilutions corresponding with 1 g. mol. per 16, 32, 64, 128, 256, 512, and 1024 litres have been determined. The mean values of the respective dissociation constants of sulphoacetic and  $\alpha$ -sulphopropionic acids calculated therefrom are  $8.9 \times 10^{-5}$  and  $6.0 \times 10^{-5}$  J. S. G. T.

**The *cis*- and *trans*-Iridodichloro-oxalates.** Optical Resolution of the *cis*-Potassium Salt. MARCEL DELÉPINE (*Compt. rend.*, 1922, 175, 1408—1411).—Potassium iridodichloro-oxalate,  $K_2[IrCl_2(C_2O_4)_2]$ , as prepared by Vèzes and Duffour (cf. A., 1909, i, 762) was found to occur in the *cis*- and *trans*-forms, and the *cis*-form was resolved into its two optical isomerides by means of its strychnine salt. The *l*-salt is the less soluble and has  $[\alpha]_D -23.8^\circ$ . The active salts are more soluble than the racemic mixture. The *trans*-salt is not resolved by means of its strychnine salt. The *cis*- and *trans*-isomerides are capable of being transformed into one another under suitable temperature conditions. W. G.

**Investigations on the Dependence of Rotatory Power on Chemical Constitution. XVI. The Di- $\alpha$ - $\beta$ -octyl Esters of the Saturated Dicarboxylic Acids.** LESLIE HALL (T., 1923, 23, 32—44).

**The Syntheses of  $\gamma$ -Hydroxy- and  $\alpha$ -Amino- $\gamma$ -hydroxyimelic Acids.** HERMANN LEUCHS and WERNER NAGEL (*Ber.*, 1922, 55, [B], 3950—3960).—The compounds are prepared from the lactone ester,

$$\begin{array}{c} \text{CO} \text{---} \text{O} \\ | \quad \diagup \\ \text{CH}_2 \text{---} \text{CH}_2 \end{array} > \text{CH} \cdot \text{CH}_2 \cdot \text{CH}(\text{CO}_2\text{Et})_2$$
 described by Leuchs and Möbis (A., 1909, i, 361). Attempts to halogenate the lactone ester, or the corresponding acid in the malonic residue and subsequently to eliminate the carbethoxy- or carboxy-group did not lead to satisfactory results, since only impure, non-crystalline products could be obtained which, even after re-esterification, could not be distilled without decomposition. The lactone ester is transformed by aniline at  $160\text{--}170^\circ$  into the *mono-anilide*,  $\text{C}_{16}\text{H}_{19}\text{O}_5\text{N}$ , lustrous leaflets, m. p.  $79\text{--}80^\circ$ . Hydrolysis of the lactone ester and subsequent removal of carbon dioxide from the product leads to the formation of the lactone of  $\gamma$ -hydroxypimelic acid,

$$\begin{array}{c} \text{CO} \text{---} \text{O} \\ | \quad \diagup \\ \text{CH}_2 \text{---} \text{CH}_2 \end{array} > \text{CH} \cdot [\text{CH}_2]_2 \cdot \text{CO}_2\text{H}$$
, four- or six-sided plates, m. p.  $80\text{--}82.5^\circ$ . It is converted by methyl alcohol and hydrogen chloride into methyl  $\gamma$ -chloropimelate which could not be isolated in a homogeneous condition, but is characterised by its conversion by ammonia into  $\beta$ -pyrrolidonepropionamide,

colourless needles, m. p.  $144\text{--}145^\circ$  (decomp.) when slowly heated. Hydroxypimelolactone is brominated by Volhard's method and the product is converted by methyl alcohol into the *methyl* ester

of  $\alpha$ -bromo- $\gamma$ -hydroxypimelolactone which could not be distilled without decomposition; the brominated ester is hydrolysed with boiling hydrobromic acid and the resulting acid, which could not be caused to crystallise, is aminated with aqueous ammonia. The expected products could only be isolated in the form of the copper salts, one of which ( $+H_2O$ ), sky-blue crystals, is the normal salt of  $\gamma$ -hydroxy- $\alpha$ -aminopimelic acid,  $OH\cdot CH<\begin{smallmatrix} CH_2\cdot CH(NH_2)\cdot CO_2 \\ CH_2\cdot CH_2\text{---}CO_2 \end{smallmatrix}>Cu$ , whereas the remaining two, greyish-blue crystals ( $+\frac{1}{2}H_2O$ ) and paler, greyish-blue needles ( $+\frac{1}{2}H_2O$ ), are considered to be derived from the two racemic forms of  $\alpha$ -aminopimelolactone,

The lactone ester is converted by ethyl bromide in the presence of alcoholic sodium ethoxide into the corresponding  $\alpha$ -ethyl derivative,

which is hydrolysed to a non-crystalline acid and is converted by methyl alcoholic ammonia into the *di-amide*,  $C_{10}H_{16}O_4N_2$ , colourless prisms or oblique plates, m. p.  $170\text{--}171^\circ$ . The acid is transformed by loss of carbon dioxide into  $\alpha$ -ethyl- $\gamma$ -hydroxypimelolactone, m. p.  $89\text{--}91^\circ$ , to which the constitution  $CO\text{---}O > CH\cdot [CH_2]_2\cdot CO_2H$ , is assigned. The latter substance is  $CH_2Et\cdot CH_2$

treated with bromine and a trace of phosphorus at  $100^\circ$  and the product, after being purified through the methyl ester, is treated successively with hydrobromic acid and ammonia. The product is isolated as a homogeneous copper salt,  $(C_8H_{14}O_4N)_2Cu\cdot\frac{1}{2}H_2O$ , although the constitution of the parent acid indicates the existence of four racemic isomerides; the corresponding free acid could only be obtained as a non-crystalline, very hygroscopic mass.

H. W.

**Keto-enolic Tautomerism. I. Desmotropy-isomerism of Ethyl Diacetylsuccinate.** H. P. KAUFMANN (*Annalen*, 1922, 429, 247—283).—A general account of this work has already appeared (*A.*, 1922, i, 985). The investigation shows that in 0.1N-alcoholic solution at  $30^\circ$  ethyl diacetylsuccinate becomes equilibrated to an approximation of 1 or 2% in twenty-four hours, and that the mixture then contains 10% of the  $\gamma$ -ester (diketo), 30% of the  $\beta$ -ester (diketo), 16% of the  $\alpha_2\beta$ -ester (mono-enol), and 44% of the  $\alpha_1\beta$ -ester (mono-enol). C. K. I.

**The Amphoteric Nature of the Carbonyl Group.** ERICH MÜLLER (*Z. angew. Chem.*, 1922, 35, 689—692, 698—700).—In a lecture delivered before the Dresden Chemical Society, the author gives an extended general account of his work on the electrolysis and catalytic decomposition of solutions of formaldehyde and related compounds and outlines his views on the hydration of formaldehyde to  $CH_2(OH)_2$  and the amphoteric nature of the hydrate. The observations are extended to other substances

containing the carbonyl group, such as ketones, carboxylic acids, and carbon monoxide. The assumption of the formation of ions, the existence of which cannot be demonstrated or the quantity measured, is justified by analogy with inorganic compounds such as the complex cyanides, and by the fact that the very involved behaviour of formaldehyde cannot be so clearly and uniformly explained by any other hypothesis.

H. W.

**The Photolysis of Carbonic Acid.** EMIL BAUR and A. REBER (Ann. *Helv. Chim. Acta*, 1922, 5, 828—832).—Moore and Webster are stated to have obtained formaldehyde from carbon dioxide solutions by the action of sunlight in presence of colloidal oxides of uranium or ferric iron (A., 1913, i, 1303). The present authors have repeated these experiments and have not succeeded in detecting the formation of oxalic acid, glyoxylic acid, formic acid, or formaldehyde. Failure to confirm the results obtained by the above investigators may be due to their having omitted to describe with sufficient exactitude their experimental conditions.

E. H. R.

**Acraldehyde Transformations and Antioxygenisers.**

HARLES MOUREU and CHARLES DUFRAISSE (*Bull. Soc. chim.*, 1922, [3], 31, 1152—1176; cf. Moureu and Dufraisse, A., 1919, i, 574; Moureu and Lepape, A., 1919, i, 574; 1920, i, 10; Moureu, Dufraisse, and Robin, A., 1920, i, 143; Moureu, Dufraisse, Robin, and Pougnet, A., 1920, i, 144; Moureu, Dufraisse, Lepape, Robin, Pougnet, Putaric, and Boismenu, A., 1921, i, 395; Moureu and Dufraisse, A., 1922, i, 250, 824).—A review of previous publications showing the trend of the work leading to the stabilisation of acraldehyde by addition of pyrocatechol and also by other phenols is followed by development of the subject in the direction of reviewing the chief substances capable of undergoing autoxidation and also of detecting the antioxygenising function in substances other than phenols. The oxidation of the acraldehyde appears to be a necessary preliminary to the formation of disacryl and the addition of a enol inhibits the change. But on submitting pure acraldehyde to the action of oxygen some disacryl is always formed, the quantity appearing to vary for no definite reason, although the transformation into disacryl was not observed to take place to any considerable extent in the presence of excess of oxygen. These facts appearing to be somewhat contradictory, the action of light on acraldehyde was investigated. The results showed that light effects the condensation into disacryl in absence of oxygen, and, conversely, that acraldehyde undergoes no condensation when prepared and kept in the dark and free from contact with oxygen. In absence of it, extremely small quantities of oxygen bring about the condensation, and the authors regard the phenomenon as one of catalysis, suggesting that a peroxide of acraldehyde is the catalyst. The theory put forward to account for the lack of condensation in excess of oxygen is based on the supposed existence of two species of acraldehyde molecule, one of which is activated. These molecules combine with oxygen but when oxygen is absent they

combine with each other. This is shown by the fact that acetaldehyde in contact with oxygen over mercury remains clear, the mercury meanwhile rising in the tube, but when the mercury ceases to rise oxidation is no longer occurring and the acetaldehyde becomes opaque. The time at which the latter change takes place may be predicted by extrapolating the curve obtained by plotting rise of mercury against time. Reasons are given for continued use of the term "antioxygeniser" (cf. Seyewetz and Sisley, A., 1922, ii, 628). H. J. E.

**The Hydrogenation of Aldehydes and Ketones in Presence of Pure and Impure Platinum Black.** FAULLEBIN (*Compt. rend.*, 1922, 175, 1077—1079).—In the reduction of aldehydes and ketones to alcohols in presence of platinum black, considerable experimental difficulties are experienced. The action is slow, the activity of the catalyst is in many cases extremely limited, and the yields obtained are poor owing to the formation of hydrocarbons. If, however, the catalyst is prepared by the reduction of chloroplatinic acid containing 5% of its weight of ferric chloride, good yields are obtained, especially in the case of aromatic aldehydes, and the speed of the reaction is increased. If the ferric chloride is replaced by iridium chloride, similar advantages are obtained, but to a lesser extent. In hydrogenating an ethyl acetate solution of 4-piperonyl-2-butanone in presence of "ferric platinum" to the corresponding secondary alcohol, hitherto unknown, a quantitative yield was obtained. The alcohol is not described. H. J. E.

**Syntheses by means of Sodamide.** A. HALLER (*Bull. Soc. chim.*, 1922, [iv], 31, 1073—1144).—A lecture delivered before the Société Chimique de France in which the use of sodamide as a reagent is discussed mainly with regard to the work of the author and his collaborators. The work surveyed comprises substitution reactions of ketones and nitriles, the action of the alkyl derivatives so obtained on various cyclic compounds and also the decomposition and condensation reactions which may be effected by the use of sodamide. The chief papers to which reference is made are those of von Auwers and Krollpfeiffer, A., 1915, i, 818; Bodroux and Taboury, A., 1910, i, 257; Cornubert, A., 1921, i, 730; Haller, A., 1904, i, 600; 1905, i, 214, 602; 1913, i, 629, 984, 1357; 1914, i, 418; Haller and Bauer, A., 1908, i, 987; 1909, i, 108, 654; 1910, i, 219, 300; 1911, i, 299, 726; 1913, i, 488, 829; 1914, i, 418, 549, 724; 1915, i, 411; 1918, i, 24, 428; 1922, i, 258; Haller and Benoist, A., 1912, i, 570; 1922, i, 350; Haller and Cornubert, A., 1914, i, 291, 842, 968; 1920, i, 390, 441; Haller and Louvriér, A., 1918, i, 397; Haller and Ramart-Lucas, A., 1914, i, 1072; 1917, i, 665. H. J. E.

**Diacetone-glucose [Diisopropylidene-glucose].** P. A. LEVENE and G. M. MEYER (*J. Biol. Chem.*, 1922, 54, 805—807).—When oxidised with nitric acid, the monomethyl glucose obtained from diisopropylidene-glucose yields a methyl saccharolactone,

$\gamma$ -H<sub>10</sub>O<sub>7</sub>, m. p. 206–207° (after sintering and darkening at 190°),  $[\alpha]_D^{25} +15^\circ$  (cf. Irvine and Hogg, T., 1914, 103, 1386). The production of this compound indicates that the isopropylidene radicals in diisopropylidene-glucose are attached to the  $\alpha$  and  $\epsilon$  carbon atoms. If diisopropylidene-glucose has the structure of a  $\gamma$ -glucose Irvine and Patterson, T., 1922, 121, 2146), the methyl group in the accharolactone will be attached to the  $\gamma$ -carbon atom; otherwise, it will be in the  $\beta$ -position. E. S.

**Glucosides. XI. The Glucosides of Glycerol.** P. KARRER and O. HURWITZ (*Helv. Chim. Acta*, 1922, 5, 864–869).—With the object of synthesising a glucoside of glycerol of which the constitution could not be open to doubt, the action of acetobromoglucose on isopropylidene-glycerol in presence of silver carbonate was studied. The reaction proceeded smoothly, giving a good yield of

$\begin{array}{c} \text{H}_2\text{O} \\ \diagup \quad \diagdown \\ \text{H}-\text{O} \end{array} \text{CMe}_2$   $\alpha$ -tetra-acetyl-d-glucosidoglycerol iso-propylidene ether (annexed formula), white crystals, m. p. 132°,  $[\alpha]_D^{25} -20.77^\circ$ . By careful hydrolysis of this compound with dilute sulphuric acid the acetone residue was removed, leaving  $\alpha$ -tetra-acetyl-d-glucosido-glycerol, an amorphous substance which can be readily reconverted into the isopropylidene derivative. By the action of acetic anhydride on the amorphous substance the glycerol residue is acetylated, with formation of  $\alpha$ -(tetra-acetyl-d-glucosido)-glycerol  $\beta$ -diacetate, a well-crystallised compound, m. p. 98°,  $[\alpha]_D^{25} -30.96^\circ$ . Alkaline hydrolysis of the last gave 1- $\beta$ -d-glucosidoglycerol,  $\text{OH}\cdot\text{CH}_2\cdot\text{CH}(\text{OH})\cdot\text{CH}_2\cdot\text{O}\cdot\text{C}_6\text{H}_{11}\text{O}_5$ ,  $[\alpha]_D^{25} -27.72^\circ$ . The  $\beta$ -configuration of the glucoside is proved by its ready hydrolysis by emulsin. It appears to be identical with the glyceryl glucoside synthesised by Bourquelot, Bridel, and Aubry by means of emulsin from glycerol and dextrose (A., 1917, i, 379). E. H. R.

**Glucosido-trimethylammonium Salts.** P. KARRER and J. ER KULE (*Helv. Chim. Acta*, 1922, 5, 870–876).—It was shown by Karrer and Smirnov (A., 1921, i, 766) that when tetra-acetyl-neosidotrimethylammonium bromide is submitted to alkaline hydrolysis, L-glucosan is formed. It is now found that by acid hydrolysis only the acetyl groups are removed, and d-glucosido- $\alpha$ -trimethylammonium bromide is formed (using hydrobromic acid for the hydrolysis) as hygroscopic crystals, m. p. 161–162°;  $[\alpha]_D^{25} +5.0^\circ$ . The hydroxide,  $\text{C}_6\text{H}_{11}\text{O}_5\cdot\text{NMe}_3\cdot\text{OH}$ , was prepared in solution by the action of silver hydroxide on the bromide or chloride; it is a strong base, but decomposes with evolution of trimethylamine when its aqueous solution is warmed. The chloride forms very hygroscopic crystals; the iodide, transparent, slightly hygroscopic crystals, m. p. 162–163°; the chloroplatinate, orange-brown crystals; chloro-pyrate, beautiful yellow needles, m. p. 141°.

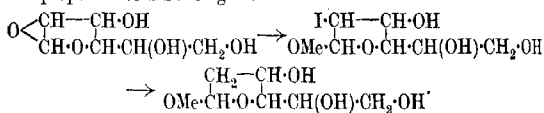

Tetra-acetyl-d-glucosido- $\alpha$ -trimethylammonium bromide forms rhombic crystals ( $a:b:c=0.4520:1:0.3443$ ); the hydroxide resembles the parent compound in preparation and properties; the chloride forms colourless hygroscopic crystals, m. p. 173°;  $[\alpha]_D^{25} +6.26^\circ$ ; the perchlorate forms microscopic needles, m. p. 190°; the picrate

crystallises in fine, yellow needles, m. p. 133°; the *chloroplatinate* in fine orange needles, m. p. 209–210° (decomp.), and the *chloroaurate* yellow needles which decompose when heated. E. H. R.

**The Constitution of Glucosan.** MARC CRAMER and EDWARD H. COX (*Helv. Chim. Acta*, 1922, 5, 884–887).—The structure proposed by Pictet and Castan (A., 1920, i, 594) for glucosan has been confirmed; the objections to this formula raised by Bergmann (A., 1921, i, 648) and Irvine and Oldham (T., 1921, 119, 1744) are therefore invalid. The attempt was first made to obtain an osazone from tribenzoylglucosan, but this was unsuccessful owing to the difficulty of hydrating the substance without hydrolysing the benzoyl groups at the same time. By the action of methyl sulphate on glucosan in presence of sodium hydroxide at 35–40°, a trimethylglucosan was obtained, b. p. 210–212°/9 mm. This gives a reducing sugar when boiled with water and forms a yellow, crystalline osazone, m. p. 163–164° (decomp.). This can only be derived from a trimethylglucose of the formula

which confirms the glucosan structure under discussion. A further proof depends on the observation that when glucosan is heated in a sealed tube with methyl iodide at 125–130° an additive compound is formed which, when reduced with sodium amalgam, gives the  $\beta$ -deoxymethylglucoside described by Fischer, Bergmann, and Schotte (A., 1920, i, 422). This reaction is readily explained by the proposed formula for glucosan thus:

E. H. R.

**Cellulose Nitrate.** EUGENE C. BINGHAM and WILLIAM L. HYDEN (*J. Franklin Inst.*, 1922, 194, 731–740).—The mobility of solutions of cellulose nitrate (12.11% nitrogen) in acetone was determined by the viscometer method at various temperatures and concentrations, and with varying shearing stresses, in order to investigate whether the fluidity is a linear function of the concentration only, or whether, as seemed probable, it is influenced by the shearing stress. It was found that there was a steady increase in the mobility with the pressure, and as already known to be the case with many plastic materials, the efflux in ml. per second was a linear function of the shearing stress. When the shearing stress is extrapolated to its value when the efflux is zero, the friction or “yield value” is obtained, which may be defined as the shearing stress at the wall of the tube necessary to start the flow. The “yield value” increased with increasing concentration and with decreasing temperature. On plotting the “yield value” against temperature for a 7.708% nitrocellulose mixture, a sharp transition temperature

was indicated at 43° where the "yield value" became zero, and the material loses its plastic character and becomes a viscous liquid. It seems probable that this transition temperature is independent of the concentration. The mobility of cellulose nitrate dispersions is characterised by the great depression produced by very small percentages of the solid, a 1% solution having a mobility only 20% of that of the pure acetone, whilst that of an 8% solution is 0.1% of that of the solvent. This is one of the most noteworthy distinctions between the polar and the non-polar type of colloid. The mobility increases with the temperature in a nearly linear manner.

G. F. M.

**Cellulose Acetate.** EMIL KNOEVENAGEL and KARL KÖNIG (*Cellulosechemie*, 1922, 3, 113—122).—Gelatinisation of solutions of cellulose acetate takes place when kept in the presence of small quantities of suitable catalysts such as sulphuric acid or sulphoacetic acid, the gelatinised product becoming insoluble in the usual solvents. If the system is not completely anhydrous, as, for instance, solutions of cellulose acetate in acetone or in glacial acetic acid, this gelatinisation may be accounted for by a large decrease in the acetyl value owing to acid hydrolysis of the ester, and it takes place more rapidly as the concentration of the catalyst is increased. If the system (solution of cellulose acetate in glacial acetic acid) be rendered anhydrous by the addition of acetic anhydride, another set of conditions arises and gelatinisation may be delayed for three months, when an increase of acetyl value and a large increase in copper value, indicative of acetolysis, are recorded. When, however, moisture is totally excluded from the first, a different type of gelatinisation is characterised, which may be described as the result of condensation or polymerisation of the cellulose ester. The purified gelatinised product is then insoluble in the usual media with the exception of tetrachloroethane, the acetyl value is only slightly changed, either slightly increased or lowered, and the copper value is slightly decreased. This type of gelatinisation may be produced by completely drying 3 g. of the cellulose acetate at 105° in a glass tube, dissolving this in 100% acetic acid sufficient to give a 15% solution, and keeping this solution in a desiccator over sulphuric acid. Next day, a small quantity of catalyst, e.g., 47 mg. of sulphuric acid or 96 mg. of sulphoacetic acid, is stirred into the viscous solution, 0.476 g. of acetic anhydride is added to react with any moisture which may have been absorbed during the operations, and the tube is sealed up. Gelatinisation takes place after two to three days, but if the quantity of catalyst is increased it is further delayed. With 115 mg. or more of sulphuric acid the solution does not gelatinise, but considerable acetolysis takes place.

J. F. B.

**Hydrocellulose [Preparation of Dimethylhydrocellulose].** EMIL HEUSER and WALTER VON NEUENSTEIN (*Cellulosechemie*, 1922, 3, 101—107).—Chopped viscose fibre, partly dried and containing 6—10% of moisture, was placed in a bottle with a paraffined

cork and the air was displaced by passing dry carbon dioxide through for two hours. A current of dry hydrogen chloride was passed very slowly so that fumes appeared at the outlet after two to three hours. The bottle was then tightly closed and allowed to remain for several hours until a test showed that the hydrocellulose was completely soluble in 10% sodium hydroxide. The fibre was neutralised and washed. For methylation, 5 g. of the hydrocellulose (1 mol.) was dissolved in 50 c.c. of 10% sodium hydroxide solution (4 mols.) and after some hours 10 g. of methyl sulphate (3 mols.) were added in small quantities at a time with continuous agitation. The temperature rose to 60° after ten minutes. Subsequent operations were performed without separating the methylated product, using the same proportions of the reagents but taking the sodium hydroxide in the form of a 25% solution instead of 10%. After the fifth operation the greater portion of the methylated cellulose remained insoluble in the saline liquid. An excess of alkali was added and while hot the cellulose ether was collected. The precipitate was dissolved in cold water, the solution filtered to remove traces of under-methylated residue, and the ether which was precipitated on heating collected while hot and washed with boiling water. When completely methylated, this ether retained its solubility in cold water even after drying. Theoretical yields were obtained when the operations were performed with mechanical stirring and the maximum degree of methylation corresponded with a methoxyl content of 33.76. (See also this vol., i, 17.)

J. F. B.

**Complex Magnesium Salts. II.** G. SPACU (*Bul. Soc. Stiinte Cluj*, 1922, 1, 247—266; from *Chem. Zentr.*, 1922, iii, 1045—1046; cf. A., 1922, i, 859).—*Magnesium tetrapyridine chloride*,  $\text{Mg}(\text{C}_5\text{NH}_5)_4\text{Cl}_2$ , prepared from magnesium chloride and anhydrous pyridine at the ordinary temperature, is a white, crystalline powder; it is very hygroscopic, with separation of pyridine. This salt differs from the corresponding bromide and iodide in that it is not co-ordinately saturated. *Magnesium triethylenediamine chloride*,  $\text{Mg en}_3\text{Cl}_2$ , forms colourless crystals which cannot be resolved into their optically active components. It is highly hygroscopic. The chloride reaction is given with silver nitrate. *Magnesium diaquodiethylenediamine iodide*,  $\text{Mg en}_2(\text{H}_2\text{O})_2\text{I}_2$ , forms crystals; it is unstable in air. *Magnesium triethylenediamine sulphate*,  $\text{Mg en}_3\text{SO}_4\text{aq}$ , is a hygroscopic, white powder. *Magnesium tetrapyridine thiocyanate*,  $\text{Mg}(\text{C}_5\text{NH}_5)_4(\text{CNS})_2$ , from magnesium thiocyanate and anhydrous pyridine, forms small, colourless, highly refractive crystals; it is very hygroscopic. *Magnesium hexapyridine thiocyanate* forms large, colourless, highly refractive crystals. *Magnesium hexammine thiocyanate*,  $\text{Mg}(\text{NH}_3)_6(\text{CNS})_2$ , prepared by the action of ammonia on solid magnesium tetrapyridine thiocyanate, is a colourless powder. Magnesium tetra-aquodipyridine chloride dipotassium chloride,  $\text{Mg}(\text{C}_5\text{NH}_5)_2(\text{H}_2\text{O})_4\text{Cl}_2 \cdot 2\text{KCl}$  is obtained by prolonged shaking of powdered carnallite with anhydrous pyridine. It is a white, crystalline powder.

G. W. R.

**Preparation of Chloro-substitution Products of Hexamethylenetetramine.** ROMOLO BURATTI (Swiss Pat. 90703; from *Chem. Zentr.*, 1922, iv, 891).—An aqueous solution of hexamethylenetetramine is mixed with a solution of a hypochlorite, previously neutralised with an organic or weak mineral acid, and the mixture concentrated to the point of crystallisation. Using neutral sodium hypochlorite containing 10% of active chlorine, the reaction is as follows:  $C_6H_{12}N_4 + 4HClO = C_6H_8N_4Cl_4 + 4H_2O$ . The tetrachlorohexamethylenetetramine thereby formed separates on concentration of the solution as a colourless mass; it forms salts with acids.

G. W. R.

**A Hydrolysis of Glycine.** EMIL BAUR (*Helv. Chim. Acta*, 1922, 5, 825—828).—When a freshly prepared solution of glycine in air-free water is shaken for a long time in absence of air with animal charcoal, gradual decomposition takes place. After 240 hours at 40°, using 10 g. of charcoal to 1 g. of glycine, 17.6% of the nitrogen present is found in solution as ammonia. Since the final solution is always neutral, the reaction is probably a simple hydrolysis according to the equation  $NH_2 \cdot CH_2 \cdot CO_2H + H_2O = OH \cdot CH_2 \cdot CO_2 \cdot NH_4$ . Attempts to separate calcium glycolate from the solution were unsuccessful, but the salt was recognised microscopically.

E. H. R.

**A Series of Metallo-cysteine Derivatives.** LESLIE JULIUS HARRIS (*Biochem. J.*, 1922, 16, 739—746).—Cysteine forms metallic derivatives much more readily than cystine. The former compound was found to give coloured metallic derivatives with the following ions:  $Fe^{+++}$ ,  $Mn^{+++}$ ,  $Mn^{+2}$ ,  $Cu^{+}$ , Co, Ni, Cr, Bi. Cuprous salts give a characteristic white derivative insoluble in neutral solutions. Tin also gives a compound with it. No oxidation takes place on addition of stannic chloride, and it is suggested that owing to the strong affinity of tin for sulphur it protects that atom in cysteine from oxidation. The mercuric ion, but not the mercurous, acts as precipitant of cysteine. The colorimetric ammonia test for cysteine is only effective in the presence of traces of a metallic compound. In alkaline solution and in the presence of oxygen, the reduced metal formed an oxygen acceptor, whilst in the absence of oxygen the oxidised metal can act as an oxygen-donor, the cysteine acting as the oxidisable substance. The system is therefore reversible so long as unoxidised cysteine is present. S. S. Z.

**The Decompositions of Mercury Fulminate.** A. LANGHANS (*Z. ges. Schiess- u. Sprengstoffw.*, 1922, 17, 122—126, 131—133, 141—143, 150—153, 159—162).—The properties of the brown product produced by drying mercury fulminate for prolonged periods (A., 1922, i, 328), and the action of dilute and concentrated nitric acid, aqua regia, sulphuric acid, chlorosulphonic acid, and hydrofluoric acid on mercury fulminate are described.

Mercury fulminate dissolves readily in boiling sodium sulphite solution. Two forms of crystals are obtained from the solution, both having the formula  $HgSO_3 \cdot Na_2SO_3 \cdot H_2O$ . If enough fulminate is added to produce a marked foaming, the salt  $Na_2SO_3 \cdot 2HgSO_3 \cdot H_2O$

is obtained. When treated with concentrated sodium sulphide solution, mercury fulminate gives off a little carbon dioxide and is coloured black owing to formation of mercuric sulphide, which dissolves in excess of the sodium sulphide. With yellow ammonium sulphide, the black precipitate at first produced turns red, and cinnabar is produced. Wet mercury fulminate is converted into mercuric sulphide, ammonium thiocyanate, and carbon dioxide by treatment with hydrogen sulphide.

Grey mercury fulminate dissolves in sodium thiosulphate, giving an almost clear solution, but the solution of white fulminate is always opalescent and a greyish-black mass is gradually deposited, which, however, shows no trace of mercury globules under the microscope. The decrease of alkalinity on keeping of a thiosulphate solution in which mercury fulminate has been dissolved is ascribed to the liberation of acid owing to the oxidising action of fulminate on the thiosulphate, the reaction being analogous to that with mercuric chloride ( $\text{Na}_2\text{S}_2\text{O}_3 + 2\text{HgCl}_2 + \text{H}_2\text{O} = \text{Na}_2\text{SO}_4 + \text{Hg}_2\text{Cl}_2 + 8 + 2\text{HCl}$ ). The change of thiosulphate into sulphate was followed quantitatively by precipitating the latter with barium chloride after various intervals of time had elapsed, and the amount of sulphate formed was found to be directly proportional to the amount of fulminate added and inversely proportional to the concentration of the thiosulphate. In using Brownson's titration method for estimating mercury fulminate, 23% of the thiosulphate was found to be converted into sulphate ten minutes after the addition of the fulminate. A thiosulphate solution stronger than  $N/10$  is recommended in this determination.

The electrolytic determination of mercury in mercury fulminate was successfully carried out, using the following solutions: potassium cyanide, ammonia, pyridine, warm 10% sodium chloride, potassium bromide, yellow sodium sulphide (10%), 2% hydrogen peroxide, 5% potassium chlorate, sodium hypochlorite, hypobromite, and hypoiodite, and ammonium oxalate. The electrolytic deposition of mercury was not quantitative using sodium thiosulphate, potassium iodide, ammonium thiocyanate, or sodium picrate. H. Ü. R.

**The Salt-like Nature of Sodium Ethyl. Indirect Electrolysis of Zinc Ethyl.** FRANZ HEIN (*Z. Electrochem.*, 1922, 28, 469—471).—A solution of sodium ethyl in zinc ethyl is a good conductor of electricity, and can be readily electrolysed, giving metallic zinc at the cathode and a mixture of hydrocarbons at the anode. The gaseous products consist of 82% of ethane and ethylene in equal proportions, and the remainder contains hydrogen and butane. Their production can be represented by the equation

These experiments prove the salt-like nature of sodium ethyl, and support the view that the solution contains  $\text{Na}^+$  and either  $\text{C}_2\text{H}_5^-$  or  $\text{Zn}(\text{C}_2\text{H}_5)_2^-$  ions. The specific conductivity of a solution of 2 mols.  $\text{NaC}_2\text{H}_5$  in 3 mols.  $\text{Zn}(\text{C}_2\text{H}_5)_2$  is 0.01082 mho at 23°. Zinc ethyl, on the other hand, does not conduct the electric current appreciably.

W. E. G.

**Is Kekulé's Benzene Theory Tenable?** C. W. A. LELY (*Chem. Weekblad*, 1922, 19, 593-598).—A triangular formula is put forward for benzene, in which the six carbon atoms, lying all in one plane, are differentiated into three primary and three secondary. The three primary form a chain of three, each having two valencies saturated by the other two primaries, and two saturated by neighbouring secondaries. The three secondaries have each two valencies saturated by primaries, and two by hydrogen atoms, the latter lying in planes perpendicular to the plane of the six carbon atoms; an additional hypothesis of synchronous rotation of the hydrogen atoms or their substituents accounts for the occurrence of only three isomeric disubstituted benzenes, and the absence of optical isomerism. Numerous reactions are cited to support the new formula, and the idea is extended to put forward formulæ for naphthalene, Willstätter's *cyclooctatetraene*, anthracene, etc.

S. I. L.

**Specimens of Cymene and Ethylbenzene of Different Origin.** K. VON AUWERS and H. KOLLIGS (*Ber.*, 1922, 55, [B], 3872-3879).—In a previous communication (*A.*, 1922, ii, 174), it has been pointed out that the physical constants of hydrocarbons of the benzene series, and in particular the refractive indices, are frequently dependent on their mode of production. Since particularly marked differences in the various specimens are noticeable in the case of cymene, the hydrocarbon has been re-examined and the observations have been extended to ethylbenzene as a simple representative of the series.

It is found that the "cymene" prepared from toluene, isopropyl bromide, and aluminium chloride is, contrary to the general rule, a meta-derivative, since it gives isophthalic acid when oxidised.

Specimens of *p*-cymene obtained from *p*- $\beta$ -iodoisopropyltoluene, cuminol, terpinene,  $\alpha$ -terpineol, and *p*- $\alpha\alpha$ -dichloroisopropyltoluene, and oil of Ajowan have closely similar physical constants if the preparation first mentioned (the uniformity of which is somewhat doubtful) is not taken into account. It is remarkable, however, that *p*-cymene derived from camphor has a particularly low refractive index; even lower values have been observed by Wheeler (Schimmel and Co., Rep., 1921, 105) for a preparation from spruce oil of turpentine.

Specimens of ethylbenzene have been examined which are obtained by reduction of freshly prepared styrene by sodium and alcohol, of acetophenone by amalgamated zinc and hydrochloric acid, by Fittig's method from bromobenzene and ethyl bromide, by Friedel and Crafts' process from thiophen-free benzene and ethyl bromide, and by the action of concentrated hydrochloric acid at 130° on *p*-ethylbenzenesulphonamide, m. p. 109°, respectively. Although all the preparations are to be regarded as "pure" in the generally accepted sense of the term, they exhibit differences in their physical constants similar to those observed with cymene. The products obtained from styrene or by Clemmensen's method have higher densities and refractive indices, whereas the constants

of all the other specimens agree well among themselves and with the values recorded previously.

Since there can be no question of steric influences in the case of ethylbenzene, it appears to be established that the differences are due to traces of impurity which cling obstinately to the various specimens. These cannot be detected by elementary analysis. Attempts to use the determination of the heat of combustion as a criterion of purity do not appear to be successful. H. W.

**Investigations on the Dependence of Rotatory Power on Chemical Constitution. XVII. A New Type of Walden Inversion.** HENRY PHILLIPS (T., 1923, 123, 44—59).

**Nitration of 3-Chloroacenaphthene.** GLADYS FARNELL (T., 1923, 123, 60—61).

**Studies in the *n*-Butyl Series. II. The Four Stereo-isomeric  $\beta$ -*Di-p*-tolylamino-*n*-butanes.** GILBERT T. MORGAN and WILFRED JOHN HICKINBOTTOM (T., 1923, 123, 97—105).

**The Reduction of Nitriles with Hydrogen in Presence of Nickel.** HANS RUPE and KARL GLENZ (*Helv. Chim. Acta*, 1922, 5, 937—942).—When optically active valeronitrile was reduced with hydrogen in presence of nickel, instead of the expected hexylamine, the secondary amine, dihexylamine, was obtained. Reduction of the nitrile with sodium and alcohol readily gave optically active hexylamine. The reaction appears to be general; since phenylacetoneitrile and  $\beta$ -phenylpropionitrile likewise gave almost entirely secondary amine when reduced with hydrogen and nickel.  $\alpha$ -Cyanocamphor did not give the corresponding secondary amine, but a base which has not been identified. When *o*-tolylearbylamine was used, it acted as a poison towards the nickel catalyst, and a poor yield of a base was obtained, probably methyl-*o*-toluidine.

The dihexylamine obtained from ordinary amyl alcohol through the cyanide had b. p. 109—115°/12 mm.; its hydrochloride,  $C_{12}H_{28}NCl$ , forms lustrous leaves; the nitrosoamine is an oil with an aromatic odour giving Liebermann's nitroso-reaction. Di- $\beta$ -phenylethylamine,  $(C_6H_5 \cdot CH_2 \cdot CH_2)_2NH$ , from phenylacetoneitrile, is a viscous oil; its hydrochloride,  $C_{16}H_{26}NCl$ , forms white, lustrous leaflets; the nitrosoamine forms white leaflets, m. p. 53—54°. Di- $\gamma$ -phenylpropylamine,  $NH(CH_2 \cdot CH_2 \cdot CH_2Ph)_2$ , gives a hydrochloride,  $C_{18}H_{24}NCl$ , white, silky leaflets; the nitrosoamine crystallises in white, felted needles, m. p. 55—56°. E. H. R.

**Phenyltrimethylammonium Perhalides.** HAMILTON MC-COMBE and THOMAS HAROLD READE (T., 1923, 123, 141—153).

**The Thiocarbimide Reaction.** SHINTARO KODAMA (*Japan. J. Chem.*, 1922, 1, 83—93).—An English version of the paper previously published in Japanese (cf. A., 1921, i, 237). K. K.

**Preparation of Complex Silver Compounds of Aromatic Thiocarbarnides.** F. HOFFMANN-LA ROCHE & Co. (Swiss Pats. 90808, 91780, and 91781; from *Chem. Zentr.*, 1922, iv, 944—945).—Aryl thiocarbarnides of the composition

the aryl group being substituted or unsubstituted, in excess are treated with silver salts such as silver chloride or silver nitrate. The complex silver compounds of the *p*-hydroxyphenylthiocarbarnide of *p*-thiocarbarnidosalicylic acid,  $\text{OH}\cdot\text{C}_6\text{H}_3\cdot(\text{CO}_2\text{H})\cdot\text{NH}\cdot\text{CS}\cdot\text{NH}_2$ , m. p. 221°, are thus prepared. The latter compound is prepared from 4-aminosalicylic acid hydrochloride and ammonium thiocyanate. The complex silver compound of 6-amino-3-thiocarbarnido-10-methylacridine (from 3 : 6-diamino-10-methylacridinium chloride) is also mentioned.

G. W. R.

**The Two Forms of *o*-Methylcyclohexanol.** L. MASCARELLI (*Atti R. Accad. Lincei*, 1922, [v], 31, ii, 116—118).—Since the molecule of *o*-methylcyclohexanol contains two asymmetric carbon atoms having unequal rotatory values, four optically active and two racemic forms of this compound should exist. The compounds obtained by Godchot and Bédos (A., 1922, i, 334) and by Sabatier and Mailhe (A., 1905, i, 275) probably represent the two racemides. The cycloheptylcycloheptanol prepared by Godchot and Brun (A., 1922, i, 350) should exhibit similar optical isomerism to *o*-methylcyclohexanol. An analogous case is presented by the two modifications of decahydro- $\beta$ -naphthol (cf. Mascarelli, A., 1911, i, 964; Mascarelli and Recusani, A., 1912, i, 761).

T. H. P.

**The Oxide of Methyl- $\Delta^3$ -cyclohexene and the Dimethylcyclohexanols.** MARCEL GODCHOT and PIERRE BÉDOS (*Compt. rend.*, 1922, 175, 1411—1414).—It has previously been shown (A., 1922, i, 334) that the action of organomagnesium complexes on the oxide of cyclohexene gives ortho-substituted homologues of cyclohexanol and that the latter compounds are stereoisomerides of the secondary alcohols obtained by the catalytic hydrogenation of the corresponding phenols. It is now shown that, in a similar manner, methyl- $\Delta^3$ -cyclohexene gives a dimethylcyclohexanol different from those obtained by the catalytic hydrogenation of the xyenols.

*Methyl- $\Delta^3$ -cyclohexene oxide*, b. p. 141—142° (corr.),  $d^{14}_4$  0.949,  $n^{14}_D$  1.4518, is obtained from methyl- $\Delta^3$ -cyclohexene either by the action of iodine and yellow mercuric oxide followed by the action of solid potassium hydroxide on the product in ethereal solution, or by oxidation with perbenzoic acid. When heated with water at 130° for six hours it is hydrated, giving 1-methylcyclohexan-3 : 4-diol, m. p. 60°, b. p. 112—115°, which gives a diphenylurethane, m. p. 176—177°. The oxide, described above, reacts with magnesium methyl iodide to yield an alcohol, b. p. 173—174° (corr.), which is probably a 1 : 4-dimethylcyclohexan-2-ol. It has  $d^{18}_4$  0.9106,  $n^{18}_D$  1.452. It does not give a phenylurethane and on oxidation yields a dimethylcyclohexanone, b. p. 171° (corr.),  $d^{16}_4$  0.9044,  $n^{16}_D$  1.4427, which gives a semicarbazone, m. p. 122°. These physical constants are different

1:4:2-xenolol by catalytic hydrogenation and subsequent oxidation. W. G.

**Catalytic Hydrogenation of Liquids by means of the Common Metals. VII. Phenols.** ANDRÉ BROCHET (*Bull. Soc. chim.*, 1922, [iv], 31, 1270—1280).—The effect of temperature and pressure on the catalytic hydrogenation of phenols in presence of a reduced nickel catalyst was studied. With phenol itself, the absorption of hydrogen commences at about 50° at atmospheric pressure, and the velocity of the reaction increases rapidly as the temperature is raised to 150°. To obtain complete hydrogenation to cyclohexanol within a reasonable time, it is necessary to use pressure, however, and at 20 atmospheres and temperatures of 200—230° the absorption of 6 atoms of hydrogen per mol. was complete within an hour. For the preparation of pure cyclohexanol pressures of 10—20 atmospheres and a temperature of about 150° constitute good practical working conditions, and if an apparatus is employed in which the catalyst can be filtered from the hydrogenised product and used again with fresh phenol it is possible completely to reduce 150 g. of the latter per 1 g. of catalyst without any appreciable loss in activity. The cyclohexanol obtained boiled at 160.5°/760 mm.,  $d_4^{20}=0.950$ . The cresols are not hydrogenated appreciably below 100°, but at 150° absorption proceeds with the same facility as with phenol, and by using pressures of 10—20 atmospheres reduction to the corresponding methyl cyclohexanols was readily achieved. *o*-Methylcyclohexanol boils at 163—164°, *m*-methylcyclohexanol at 170—171°, and *p*-methylcyclohexanol at 170—171°. G. F. M.

**Catalytic Hydrogenation under Pressure in the Presence of Nickel Salts. III. Phenetidine.** JULIUS VON BRAUN and ERICH HAHN (*Ber.*, 1922, 55, [B], 3770—3779).—Under the conditions adopted by the authors, phenetidine can be hydrogenated without loss of the ethoxyl groups; the main product appears to be a mixture of stereoisomeric 4:4'-diethoxydicyclohexylamines,  $\text{OEt}\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{C}_6\text{H}_{10}\cdot\text{OEt}$ .

The hydrogenation of phenetidine is effected at 210—230° in the presence of tetrahydronaphthalene; the absorption of the gas occurs somewhat slowly, and the relative amounts of the various products appear to be considerably affected by unknown catalytic influences. About a quarter of the phenetidine used is converted into a product, b. p. 208—216°/16 mm., which can be separated by means of light petroleum into two isomeric 4-ethoxyphenyl-4'-ethoxycyclohexylamines, m. p. 78—79° and 37—38°, respectively. The isomeride of higher melting point is produced in relatively very small amount, so that it has not been possible to make a complete investigation of it. It yields a non-crystalline hydrochloride, picrate, and picrolonate, a crystalline quaternary methiodide, m. p. 156°, and an acetyl derivative, colourless crystals, m. p. 84°. The variety of lower melting point yields a non-crystalline hydrochloride, picrate, and picrolonate, an acetyl compound, m. p. 42—43°.

b. p. 235—240°/18 mm., a *nitroso*-derivative, m. p. 78°, and a very hygroscopic quaternary *methiodide* (the corresponding *methochloride* is hygroscopic, but yields a well-defined *chloroplatinate*, a micro-crystalline, orange-red powder). Fission of the quaternary ammonium hydroxide is effected very readily and gives 4-ethoxy- $\Delta^1$ -cyclohexene, a mobile liquid, b. p. 158—160° (which is converted by fuming hydrobromic acid into *trans*-1:4-dibromocyclohexane, m. p. 113°), dimethylphenetidine, m. p. 35—36° (picrate, m. p. 142°), and the tertiary base,  $C_{12}H_{27}O_2N$ , m. p. 40°, which gives a non-crystalline hydrochloride, picrate, and picrolonate.

4-Ethoxyphenyl-4'-ethoxycyclohexylamine is readily hydrolysed by concentrated hydrochloric acid at the temperature of boiling water, the ethoxyl group attached to the cyclohexyl nucleus being first affected. 4-Ethoxyphenyl-4'-hydroxycyclohexylamine,

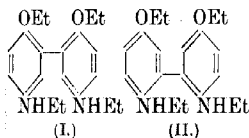

crystallises in colourless leaflets, m. p. 84—85° (*di*-p-nitrobenzoyl derivative, m. p. 192°); it loses water when distilled under diminished pressure, giving p-ethoxyphenylcyclohexenylamine,  $OEt \cdot C_6H_4 \cdot NH \cdot C_6H_9$ , a viscous, pale yellow liquid which could not be caused to solidify and has not been investigated further. 4-Hydroxyphenyl-4'-hydroxycyclohexylamine has m. p. 136—137°. 4-Ethoxyphenyl-4'-hydroxycyclohexylmethylamine,

m. p. 72°, yields a p-nitrobenzoyl compound, a pale yellow, crystalline powder, m. p. 189°.

The residues left after the distillation of 4:4'-diethoxyphenylcyclohexylamine yield a substance,  $C_{20}H_{23}O_2N_2$ , colourless crystals, m. p. 169—170°; it yields a dihydrochloride, decomp. 290°, a di-nitroso-derivative,  $C_{20}H_{26}O_4N_4$ , pale yellow crystals, m. p. 190°, and a di-acetyl compound, m. p. 240°. One of the annexed formulæ is suggested.

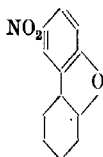

Investigations on the Dependence of Rotatory Power on Chemical Constitution. XVIII. The Di-*l*-menthyl Esters of the Saturated Dicarboxylic Acids. LESLIE HALL (T., 1923, 23, 105—113).

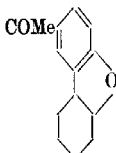

Catalytic Hydrogenation under Pressure in the Presence of Nickel Salts. II. Hexahydrodiphenylene Oxide from 1:2-Dihydroxydiphenyl. JULIUS VON BRAUN (*Ber.*, 1922, 55, [B], 3761—3770).—The catalytic reduction of 2:2'-dihydroxydiphenyl follows a somewhat unexpected course which leads to the complete hydrogenation of one nucleus and the formation of the oxide ring. The latter is extraordinarily stable towards further reduction, but readily undergoes fission when treated with oxidising agents.

Hexahydrodiphenylene oxide,  $C_6H_4 > O, C_6H_{10}$ , a colourless liquid, b. p.

138—141°/100 mm., is conveniently prepared by treating 2:2'-dihydroxydiphenyl at 230° with four atomic proportions of hydrogen and subsequent fractional distillation of the product. It is indifferent towards sodium and alcohol, zinc, and acetic acid, or magnesium phenyl bromide. It reacts slowly with bromine, but does not yield a crystalline product. Warm concentrated sulphuric acid converts it into a *monosulphonic acid*, the *sodium salt* of which is described. It is converted by cautious nitration with nitric acid (*d* 1.4) and glacial acetic acid at -15° into *nitrohexahydrodiphenylene oxide* (annexed formula), m. p. 126°, which is reduced by stannous chloride and concentrated hydrochloric acid to *aminohexahydrodiphenylene oxide*, pale yellow leaflets, m. p. 56° (*hydrochloride*, colourless needles, decomp. 250° after darkening at 225° and softening at 235°; *picrate*, m. p. 186°; *acetyl derivative*, m. p. 123°).

Hexahydrodiphenylene oxide readily becomes resinified under the conditions of the Friedel-Crafts' synthesis, but under definite conditions it can be converted into the corresponding *methyl ketone*

(annexed formula), colourless crystals, m. p. 67—68°. The *oxime* of the latter, m. p. 167°, is reduced by sodium and alcohol to *aminoethylhexahydrodiphenylene oxide*, a colourless liquid which rapidly absorbs atmospheric carbon dioxide, b. p. 210—213°/16 mm. (*hydrochloride*, m. p. 267—268° after darkening at 264°; *chloroplatinate*, decomp. 200° after gradual darkening; *picrate*, decomp. 250° after darkening at 240°). It is remarkable that the oxide ring is not ruptured during the reduction.

With oxalyl chloride, hexahydrodiphenylene oxide gives the acid,  $\text{CO}_2\text{H} \cdot \text{C}_6\text{H}_3 > \text{O}$ , colourless crystals, m. p. 250° after softening at 240°, in very poor yield.

Hexahydrodiphenylene oxide is readily oxidised by chromic acid in glacial acetic acid to  $\delta$ -o-hydroxybenzoylvaleric acid,

long, colourless needles, m. p. 94°, b. p. 240—242°/12 mm. (*oxime*, m. p. 128°; *semicarbazone*, m. p. 186°; *phenylhydrazone*, yellow leaflets, m. p. 173°; *benzoyl derivative*, m. p. 82°). The acid is slowly converted by methyl iodide and alkali in methyl-alcoholic solution into the *methoxy-acid*,  $\text{OMe} \cdot \text{C}_6\text{H}_4 \cdot \text{CO} \cdot [\text{CH}_2]_4 \cdot \text{CO}_2\text{H}$ , m. p. 82° (*semicarbazone*, m. p. 175—176°; *methyl ester*, prismatic needles, m. p. 28°).  $\delta$ -o-Hydroxybenzoylvaleric acid is smoothly converted by isatin into 2-o-hydroxyphenyl-3-propylquinoline- $\gamma$ :4-dicarboxylic acid,  $\text{C}_6\text{H}_4 \cdot \text{C}(\text{CO}_2\text{H}) \cdot \text{C} \cdot [\text{CH}_2]_3 \cdot \text{CO}_2\text{H}$ , m. p. 295° (decomp.). Molten

sodium hydroxide rapidly transforms  $\delta$ -o-hydroxybenzoylvaleric acid into phenol and adipic acid.

Nitrohexahydrodiphenylene oxide is oxidised by chromic acid to  $\delta$ -m-nitro-o-hydroxybenzoylvaleric acid, small, yellow needles, m. p. 116°, which does not appear to be readily obtainable by nitration of the parent acid.

H. W.

**Elimination of the Amino-group of Tertiary Amino-alcohols. I.** ALEX. MCKENZIE and ANGUS CAMPBELL RICHARDSON (T., 1923, 123, 79—91).

**Catalytic Hydrogenation of Liquids by means of the Common Metals. VIII. Naphthols.** A. BROCHET and R. CORNUBERT (*Bull. Soc. chim.*, 1922, [iv], 31, 1280—1285).—By the hydrogenation of  $\alpha$ - and  $\beta$ -naphthols under pressure, using a reduced nickel catalyst, both the *ac*- and *ar*-tetrahydronaphthols are obtained in each case. The hydrogenation of  $\alpha$ -naphthol at 130° gives a mixture of 85% of *ac*-tetrahydro- $\alpha$ -naphthol and 15% *ar*-tetrahydro- $\alpha$ -naphthol, the former boiling at 139—140°/17 mm. (corr.) and having  $d_4^{20}$  1.0896,  $n_D^{20}$  1.5671,  $R$  44.37, showing an exaltation +0.27. It is a thick liquid, becoming brown on prolonged contact with air. The *phenylurethane* melts at 121°. *ar*-Tetrahydro- $\alpha$ -naphthol is a solid, m. p. 68° (corr.). Hydrogenation of  $\beta$ -naphthol at 150° gives 75% of the alicyclic tetrahydro-derivative, and 25% of the phenolic derivative. *ac*-Tetrahydro- $\beta$ -naphthol is a viscous liquid which darkens on contact with air and on keeping. It boils at 144.5—145.6°/20 mm. (corr.),  $d_4^{20}$  1.0715,  $n_D^{20}$  1.5523,  $R$  44.16, showing exaltation +0.06. The *phenylurethane* melts at 99°. *ar*-Tetrahydro- $\beta$ -naphthol is a solid, m. p. 57.5°. G. F. M.

**Benzo-polymethylene Compounds. II. Hydroxy-bases and  $\beta$ -Ketones of the Tetrahydronaphthalene and Hydrindene Series.** JULIUS VON BRAUN, OTTO BRAUNSDORF, and GEORG KIRSCHBAUM (*Ber.*, 1922, 55, [B], 3648—3663).—The bromine atom of *ac*-2-bromo-1-hydroxy(alkyloxy)tetrahydronaphthalenes (A., 1921, i, 407) can be replaced readily by basic residues. The hydroxy-bases formed in this manner differ greatly from *ac*- $\beta$ -aminotetrahydronaphthalene and its alkyl derivatives, since they are relatively non-toxic and have a more or less marked antipyretic character, whereas the corresponding alkyloxy-compounds are strongly poisonous. The constitution of the latter substances is established by the mode of production, but in the case of the hydroxy-compounds the possibility that the hydroxyl group may occupy position 2 is not definitely excluded (cf. Straus and Rohrbacher, A., 1921, i, 171); comparative experiments on the fission of piperidino-derivatives by cyanogen bromide indicate that this is not the case, and that the striking difference in physiological properties is therefore attributable solely to the replacement of the hydroxyl by the alkyloxy group.

The following alkyloxy-bases are described: 2-Dimethylamino-1-ethoxytetrahydronaphthalene,  $C_6H_4 \begin{smallmatrix} \text{CH(OEt)} \\ | \\ \text{CH}_2 \end{smallmatrix} \text{---} \begin{smallmatrix} \text{CH(NMe}_2) \\ | \\ \text{CH}_2 \end{smallmatrix}$ , b. p. 152°/13 mm., and its oily hydrochloride, picrate, m. p. 199°, and methiodide, m. p. 166°;  $\beta$ -piperidino-1-ethoxytetrahydronaphthalene, an almost colourless liquid, b. p. 170—172°/10 mm.; 2-diethylamino-1-alkyloxytetrahydronaphthalene, b. p. 165°/10 mm. *ac*-1-Aminotetrahydronaphthalene is readily prepared by the reduction of 1-oximinotetrahydronaphthalene with sodium and

alcohol and is converted by  $\alpha$ -dibromopentane in boiling alcoholic solution into ac-1-piperidinotetrahydronaphthalene, a colourless liquid, b. p. 174—176°/17 mm. The hydrochloride, hydrobromide, and methiodide could not be caused to crystallise; the chloroplatinate is amorphous, whereas the picrate crystallises in dark yellow needles, m. p. 145—146°, after softening at 140°. ac-2-Piperidinotetrahydronaphthalene is a colourless, odourless liquid, b. p. 186—187°/16 mm. (hydrochloride, m. p. 230—231°; hydrobromide, m. p. 233—234°; methiodide, m. p. 209°; picrate, m. p. 203—204°). Both piperidino-compounds suffer fission under the influence of cyanogen bromide, but the production of bromotetrahydronaphthalene is much more marked with the 1- than with the 2-derivative. 2-Piperidino-1-hydroxytetrahydronaphthalene (cf. Straus and Rohrbacker, *loc. cit.*) has b. p. 192—194°/14 mm., m. p. 75—76° (hydrochloride, m. p. 185—186°; picrate, m. p. 152°; chloroplatinate, m. p. 192°). 2-Piperidino-1-benzoyloxytetrahydronaphthalene is acted on by cyanogen bromide, giving cyanopiperidine in a yield which points to the presence of the basic group in the 2- rather than in the 1-position.

ac-2-Amino-1-hydroxytetrahydronaphthalene, m. p. 109°, b. p. 160°/11 mm., is prepared by the action of concentrated ammonia solution on the corresponding bromo-compound. The hydrochloride, m. p. 227°; chloroplatinate, m. p. 215°; picrate, yellow leaflets, m. p. 192°; phenylthiocarbamide, m. p. 134°; benzylidene derivative, m. p. 115°; salicylidene derivative, m. p. 108°; acetyl derivative, m. p. 203°; p-nitrobenzoyl derivative, m. p. 228°; p-aminobenzoyl derivative, m. p. 208°, and the hydrochloride of the latter, m. p. 239°, are described. When the base is warmed with an equivalent quantity of ethylene oxide in chloroform solution it is converted into 2- $\beta$ -hydroxyethylamino-1-hydroxytetrahydronaphthalene,  $C_6H_4 \begin{matrix} \text{CH(OH)·CH·NH·CH}_2\text{·CH}_2\text{·OH} \\ \text{CH}_2 \text{---} \text{CH}_2 \end{matrix}$ , a very viscous liquid,

b. p. 190—196°/vacuum; the corresponding hydrochloride has m. p. 155°. 2-Benzylamino-1-hydroxytetrahydronaphthalene is a colourless, viscous liquid, b. p. 243—246°/13 mm. (picrate, m. p. 192°; hydrochloride, m. p. 237°). 2-Nortropyl-1-hydroxytetrahydronaphthalene, b. p. 210—212°/14 mm., yields a picrate, m. p. 174°, and an extremely hygroscopic hydrochloride. 2-Dimethylamino-1-hydroxytetrahydronaphthalene, m. p. 40° (cf. Straus and Rohrbacker, *loc. cit.*), yields a picrate, m. p. 138°, and a methiodide, m. p. 138—139°; the benzoate and acetate and its salts show little tendency towards crystallisation. The p-nitrobenzoate and p-aminobenzoate have m. p. 112° and 137°, respectively. 2-Methylamino-1-hydroxytetrahydronaphthalene picrate has m. p. 172°. 2-Diethylamino-1-hydroxytetrahydronaphthalene gives a crystalline chloroplatinate, m. p. 192°, and a liquid acetate.

If the methiodide of 2-dimethylamino-1-hydroxytetrahydronaphthalene is treated with silver oxide and the solution thus obtained is heated, tetrahydraironaphthalene oxide is produced. When the iodide is heated alone at a temperature very slightly above its melting point, it is decomposed into trimethylamine

hydrochloride and 2-ketotetrahydronaphthalene, b. p. 140°/20 mm., 130°/10 mm.,  $d_4^{20}$  1.1055 (*semicarbazone*, m. p. 190—191°), the yield being 80—85% of that theoretically possible. The behaviour of the ketone does not appear to be well expressed in the formula

$C_6H_4 \begin{smallmatrix} \text{CH}_2 \text{CO} \\ \diagup \quad \diagdown \\ \text{CH}_2 \text{CH}_2 \end{smallmatrix}$ , which does not explain the formation of an intense blue colour under the influence of air and alkali, the difficulty with which it forms additive compounds, and the apparent absence of an activated methylene group. The application of Étard's reaction to tetrahydronaphthalene gives a mixture of the 1- and 2-ketones.

*ac*-2-Dimethylamino-1-hydroxyhydrindene,

a colourless, crystalline substance which rapidly darkens when exposed to air, b. p. 153—156°/9 mm., m. p. 62°, gives a *hydrochloride*, m. p. 183—184°, a *picrate*, m. p. 145°, and a *methiodide*, m. p. 161—162°. The latter substance is decomposed when distilled under diminished pressure into trimethylamine hydriodide and  $\beta$ -ketohydrindene; the conditions of the change are more drastic and the yield of ketone is smaller than with the corresponding tetrahydronaphthalene derivative.

H. W.

#### Benzo-polymethylene Compounds. VII. Pharmacological Analogues of *ac*-2-Aminotetrahydronaphthalene.

JULIUS VON BRAUN, HEINRICH GRUBER, and GEORG KIRSCHBAUM (*Ber.*, 1922, 55, [B], 3664—3674).—Substances which contain an aliphatic amino-group in the  $\beta$ -position with respect to an aromatic nucleus have the property of causing an increase in the blood pressure. In addition to this property, *ac*-2-aminotetrahydronaphthalene has also a mydriatic action and causes a marked increase in the body temperature. The effects obviously depend on the simultaneous presence of an aromatic and a hydroaromatic ring. The examination of a number of analogous compounds has shown that similar physiological properties are exhibited by substances which contain an aliphatic amino-group in the  $\beta$ -position to the aromatic portion of the tetrahydronaphthalene complex; if this condition is fulfilled, the further mode of attachment is immaterial.

The catalytic reduction of *o*-hydroxydiphenyl with hydrogen under pressure at 210—220° in the presence of nickel salts to 2-phenylcyclohexanol is attended with considerable experimental difficulties, since the completion of the reaction is not marked by any abrupt change in the rate of absorption of the gas. The products obtained when the action is continued to the almost complete cessation of absorption are *dicyclohexyl*, b. p. 103—105°/12 mm., and 2-cyclohexylcyclohexanol, b. p. 134—135°/12 mm., which is probably a mixture of *cis*- and *trans*-isomerides (cf. Wallach, A., 1911, i, 473). The latter substance is oxidised by chromic acid to 2-cyclohexylcyclohexanone, b. p. 128—130°/10 mm. (*benzylidene* compound, m. p. 100°; *semicarbazone*, m. p.

above 200°). Less complete reduction of *o*-hydroxydiphenyl gives a mixture of phenylcyclohexane, dicyclohexyl, 2-phenylcyclohexanol, and 2-cyclohexylcyclohexanol. The alcohols are nearly exclusively produced when only six atomic proportions of hydrogen are used, but they cannot be separated conveniently from one another. Oxidation of the mixture with chromic acid gives the corresponding ketones, from which 2-phenylcyclohexanone is isolated partly in substance and partly as the *oxime*, slender needles, m. p. 174—175°; 2-phenylcyclohexanonesemicarbazone has m. p. 193°. 2-Phenylcyclohexanol, prepared by the reduction of the pure ketone with sodium and alcohol, has b. p. 143—144°/11 mm., m. p. 54—55°, and yields a phenylurethane, m. p. 138—139°. 2-Phenylcyclohexanoneoxime is reduced smoothly by sodium and alcohol to 2-phenylcyclohexylamine, b. p. 133—134°/12 mm., m. p. 59—60°. The hydrochloride, m. p. 253°, chloroplatinate, reddish-yellow needles, decomp. 222°, acetyl derivative, m. p. 130°, phenylthiocarbamide, m. p. 185°, and methiodide, m. p. 235°, are described. The base causes an increase in the blood pressure, but is not otherwise similar to *ac*-2-aminotetrahydronaphthalene, probably for the reason that the association of the aromatic and hydroaromatic nucleus is not sufficiently close.

*ac*-1-Aminomethyltetrahydronaphthalene,

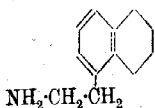

is obtained in 20% yield by the reduction of  $\alpha$ -naphthonitrile; the hydrochloride, m. p. 230°, picrate, m. p. 170°, and benzoyl derivative, m. p. 125—126°, are described. The following process does not give the base in better yield.  $\alpha$ -Ketotetrahydronaphthalene is condensed with zinc and ethyl bromoacetate to form the unsaturated ester, b. p. 183—184°/16 mm., which appears to have the double bond in the nucleus, as shown by the formula,

It is readily hydrolysed to the corresponding acid, colourless needles, m. p. 100°, which is slowly hydrogenated in the presence of palladium chloride to 1-tetrahydronaphthylacetic acid, m. p. 35—36°. The latter is convertible through the amide, but in small yield into *ac*-1-aminomethyltetrahydronaphthalene. The physiological properties of the base are similar to, but weaker than, those of *ac*-2-aminotetrahydronaphthalene.

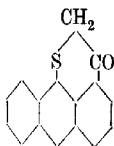

*ar*-1-Benzoylaminomethyltetrahydronaphthalene is converted by phosphorus pentachloride into *ar*-1-chloromethyltetrahydronaphthalene, b. p. 144—145°/13 mm., m. p. 50—51°. (*ar*-2-Chloromethyltetrahydronaphthalene has b. p. 141—142°/12 mm., but does not solidify when cooled.) It is converted smoothly by potassium cyanide in aqueous alcoholic solution into *ar*-1-cyanomethyltetra-

hydronaphthalene, colourless needles, m. p. 69—70°, b. p. 168—169°/10 mm. The latter is reduced by sodium and alcohol to *ar*-1- $\beta$ -aminoethyltetrahydronaphthalene (annexed formula), a colourless, somewhat viscous

liquid, b. p. 146—149°/16 mm. The corresponding *hydrochloride*, m. p. 245° (decomp.), *picrate*, small leaflets, m. p. 231°, and *benzoyl* derivative, m. p. 123°, are described. Physiologically the base closely resembles *ac*-2-aminotetrahydronaphthalene. H. W.

**The Action of Sulphur Chloride on Anthracene.** P. FRIEDLÄNDER and A. SIMON (*Ber.*, 1922, 55, [B], 3969—3980).—Anthracene is readily converted by sulphur chloride into 9-anthryl dithiochloride,  $C_{14}H_9S_2Cl$ , yellowish-red, lustrous crystals, m. p. 117—118° (decomp.), when rapidly heated; it reacts readily with ammonia and aromatic bases but only gives resinous products. With dimethylamine, it gives the compound,  $C_{14}H_9S_2NMe_2$ , yellow prisms, m. p. 70—71°; the corresponding *piperidide* is described. A solution of anthryl dithiochloride in benzene is converted by a concentrated solution of sodium sulphite at the atmospheric temperature into sodium 9-anthryl thiosulphate,  $C_{14}H_9S\cdot SO_3Na$ , pale yellow leaflets; the corresponding barium salt is intensely yellow, but appears to yield a colourless hydrate. 9-Anthryl hydrogen thiosulphate,  $C_{14}H_9S\cdot SO_3H$ , crystallises in slender, colourless needles; it decomposes slowly in warm aqueous solution, rapidly in the presence of hydrochloric acid, into sulphuric acid and 9-anthryl disulphide, lustrous, orange-yellow octahedra, m. p. 223° (see later); this compound (in addition to thiosulphate) is also produced when a solution of the sodium salt is warmed with sodium hydroxide. 9-Thiolanthracene, orange-yellow octahedra, m. p. 90—91°, is most conveniently prepared by the action of anthryl dithiochloride on a solution of hydrated sodium sulphide in methyl alcohol; the corresponding sodium salt forms orange-yellow leaflets, and the methyl ether, needles, m. p. 153°. The thiol is the sulphur analogue of anthranol (Meyer, A., 1911, i, 193), but, unlike this compound, it exhibits little tendency to pass into a substance of the anthrone type. 9-Anthryl disulphide (see above) is obtained quantitatively by the oxidation of an alkaline solution of the thiol with potassium ferricyanide. 9-Anthrylthiolacetic acid,  $C_{14}H_9S\cdot CH_2\cdot CO_2H$ , slender, very pale yellow needles, m. p. 164°, is prepared by the addition of the sodium compound of 9-thiolanthracene to an alkaline solution of sodium chloroacetate; the sodium salt, lustrous leaflets, ammonium salt, and the methyl ester, small, yellow needles, m. p. 67°, are described. The acid is converted by phosphorus pentachloride in the presence of light petroleum (but less conveniently by thionyl chloride, which also causes chlorination) into 9-anthrylthiolacetyl chloride, compact, yellow needles, from which the corresponding amide, colourless needles which soften but do not melt at 197°, is prepared. The chloride is converted by aluminium chloride in the presence of light petroleum at 30—40°, into 3-keto-peri-anthracenopenthiophen (annexed formula), small, tile-red crystals, m. p. 150—152°. The substance is transformed by hot nitrobenzene into bis-peri-anthracenopenthiophen,  $C_{14}H_9\langle\begin{smallmatrix} S \\ CO \end{smallmatrix}\rangle C:C \langle\begin{smallmatrix} S \\ CO \end{smallmatrix}\rangle C_{14}H_9$ , dark

green needles, and condenses with  $\alpha$ -isatinanilide in the presence of pyridine to give 3'-indoxyl-(2:2')-peri-anthracenopenthiophen,  

$$C_{14}H_8 \begin{array}{c} \text{S} \\ \diagup \quad \diagdown \\ \text{CO} \end{array} \text{C} \cdot \text{C} \begin{array}{c} \text{CO} \\ \diagdown \quad \diagup \\ \text{NH} \end{array} C_6H_4$$
, dark coloured needles. H. W.

Investigations on the Dependence of Rotatory Power on Chemical Constitution. XV. Some *n*-Alkyl Ethers of *d*-Benzylmethylcarbinol. HENRY PHILLIPS (T., 1923, 123, 22—31).

The Formation and Stability of *spiro*-Compounds. X. *spiro*-Compounds Derived from *cyclo*Heptane. JOHN WILLIAM BAKER and CHRISTOPHER KELK INGOLD (T., 1923, 123, 122—133).

Preparation of Esters. LABORATOIRE-USINE (F.P. 531960; from *Chem. Zentr.*, 1922, iv, 943).—Alkyl carboxylates are heated with aluminium derivatives of alcohols. The reaction takes place according to the equation,  $3R \cdot CO_2R' + Al(OR'')_3 = 3R \cdot CO_2R' + Al(OR'')_3$ , where  $R''$  has a higher molecular weight than  $R'$ . The aluminium alkyloxides are prepared by heating the corresponding alcohols with aluminium amalgam or other easily decomposed aluminium alloys. For example, aluminium amyl oxide and ethyl acetate give amyl acetate. *Amyl phenylacetate*,  $\alpha$ -*phenylethyl acetate*,  $\beta$ -*phenylethyl phenylacetate*, and *linalyl acetate* are similarly prepared. G. W. R.

Some Esters of Anisic Acid. L. G. RADCLIFFE and W. H. BRINDLEY (*Perf. Essent. Oil Rec.*, 1922, 13, 414—415).—Anisic acid was obtained in almost theoretical yield by the oxidation of anisaldehyde with alkaline permanganate. Cannizzaro's method—treatment of the aldehyde with potassium hydroxide—proved unsatisfactory, large amounts of unchanged material being recovered. The following esters were prepared by saturating solutions in the respective alcohols with dry hydrogen chloride. Methyl ester, m. p. 48°, b. p. 256°. Ethyl ester, m. p. 7—8°, b. p. 263°,  $d_4^{15}$  1.106,  $n_D^{15}$  1.5245. *n*-Propyl ester, b. p. 176°/15 mm.,  $d_4^{15}$  1.09,  $n_D^{15}$  1.5149. *n*-Butyl ester, b. p. 183°/40 mm.,  $d_4^{15}$  1.054,  $n_D^{15}$  1.5141. *iso*Butyl ester, b. p. 170°/46 mm.,  $d_4^{15}$  1.052,  $n_D^{15}$  1.5072. *iso*Amyl ester, b. p. 188°/30 mm.,  $d_4^{15}$  1.040. Phenylpropyl ester, b. p. 256°/35 mm.,  $d_4^{15}$  1.111,  $n_D^{15}$  1.5623. Only the lower members of the aliphatic series have pronounced odours, the higher members are practically odourless. G. F. M.

Preparation of Alkyl Dihydroxynaphthoylbenzoates. SOCIETY FOR CHEMICAL INDUSTRY IN BASLE (Swiss Pats. 90806, 91106, and 91107; from *Chem. Zentr.*, 1922, iv, 890).—1:5- or 1:6-Dihydroxynaphthoyl-*o*-benzoic acid is esterified in the usual way with aliphatic alcohols. *Allyl* 1:6-dihydroxynaphthoyl-*o*-benzoate forms white, prismatic needles, m. p. 128°. *Ethyl* 1:6-dihydroxynaphthoyl-*o*-benzoate forms slightly yellow crystals, m. p. 156°. *Ethyl* 1:5-dihydroxynaphthoyl-*o*-benzoate forms white needles, m. p. 146°. G. W. R.

**The Degradation of Hydroaromatic Acids of the Glutaric Acid Series.** A. WINDAUS, F. KLÄNHARDT, and G. REVEREY (*Ber.*, 1922, 55, [B], 3981—3987).—In a previous communication (Windaus and Klänhardt, A., 1921, i, 392), it has been shown that the silver salts of the aliphatic glutaric acids react with iodine in accordance with the schemes  $\text{CO}_2\text{Ag}[\text{CH}_2]_3\text{CO}_2\text{Ag} + \text{I}_2 = 2\text{AgI} + -\text{O}-\text{CO}[\text{CH}_2]_3\text{CO}-\text{O}-$  and  $-\text{O}-\text{CO}[\text{CH}_2]_3\text{CO}-\text{O}- \rightarrow$  (a)  $\text{CO}[\text{CH}_2]_3\text{CO} + \text{O}$ , or (b)  $\text{CO}[\text{CH}_2]_2\text{CH}_2 + \text{CO}_2$ , or (c)  $\text{CH}_2\text{:CHMe} +$

$2\text{CO}_2$ . The observations have now been extended to acids which may be regarded as glutaric acids of which one or more carbon atoms are members of a hydroaromatic ring. The action is found to occur normally in the case of the *cis*-acids unless the glutaric acid substitutes a five-membered ring in the 1:3-position.

Silver *cyclohexanediacetate* is converted by iodine into the

lactone,  $\text{CH}_2\langle\text{CH}_2\text{CH}_2\rangle\text{C}\langle\text{CH}_2\text{O}\text{CH}_2\text{CO}\rangle$ , a colourless, viscous liquid,

b. p. 273°/759 mm. (slight decomp.), 154°/16 mm.,  $d_{15}^{20}$  1.0755,  $n_D^{20}$  1.48386,  $n_D^{20}$  1.48668,  $n_D^{20}$  1.48631. The *barium* and *potassium* salts

of the corresponding hydroxy-acid have been prepared. The lactone is oxidised by alkaline permanganate or by potassium dichromate and sulphuric acid to *cyclohexane-1-acetic-1-carboxylic*

acid,  $\text{CH}_2\langle\text{CH}_2\text{CH}_2\rangle\text{C}(\text{CO}_2\text{H})\text{CH}_2\text{CO}_2\text{H}$ , colourless prisms, m. p. 131° (uncorr.) [cf. Norris and Thorpe, T., 1921, 119, 1206].

Silver *cis*-hexahydrohomophthalate is readily converted by

iodine into *hexahydrophthalide*,  $\text{CH}_2\text{CH}_2\langle\text{CH}\text{CH}_2\rangle\text{O}$ , a colourless

liquid, b. p. 134—138°/25 mm., the constitution of which is established by its oxidation with potassium dichromate and sulphuric acid to *cis*-hexahydrophthalic acid; the same lactone is obtained in smaller yield and with greater difficulty from silver *trans*-hexahydrohomophthalate.

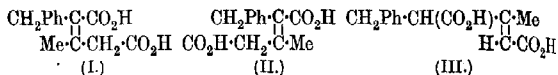

*iso*Phthalic acid is hydrogenated in glacial acetic acid solution to a mixture of *cis*- and *trans*-hexahydro*iso*phthalic acids, in which the former preponderates the more considerably when the reduction proceeds rapidly; the *cis*-acid, however, is not converted into the *trans*-variety if subsequently agitated with glacial acetic acid and platinum black. Silver *cis*-hexahydro*iso*phthalate and iodine give the lactone of *cis*-cyclohexanol-3-carboxylic acid, b. p. 127—135°/21 mm. (cf. Perkin and Tattersall, T., 1907, 91, 488) the identity of which is established by converting it into *cis*-cyclohexanol-3-carboxylic acid, m. p. 132—133°, and *cis*-3-bromocyclohexanecarboxylic acid, m. p. 61—63°.

Silver camphorate is transformed by iodine into camphoric anhydride; a neutral lactone does not appear to be produced.

H. W.

**The Chemistry of the Glutaconic Acids. XIII. The Isomerism due to Retarded Mobility.** JOCELYN FIELD THORPE and ARTHUR SAMUEL WOOD (T., 1923, 123, 62—64).

**$\alpha$ -Benzyl- $\beta$ -methylglutaconic Acids.** FRANZ FEIST and E. D. RAUTERBERG (*Ber.*, 1922, 55, [B], 3697—3705).—In extension of previous investigations (A., 1922, i, 521, 522, 553), the authors have examined the ozonisation of a substituted glutaconic acid which might be expected to yield stable fission products, and for this purpose have selected  $\alpha$ -benzyl- $\beta$ -methylglutaconic acid (cf. Bland and Thorpe, T., 1912, 101, 1740). It is shown that the (normal) acid of higher melting point and its esters and also the esters of the labile acid are constituted in accordance with the annexed formula (I), whereas the labile acid appears to be a mixture of the two *trans*-forms (II and III). The complex nature of the

latter product explains its low melting point as compared with that of the homogeneous *cis*-acid.

*cis*- $\alpha$ -Benzyl- $\beta$ -methylglutaconic acid gives an *ozonide* which is hydrolysed to phenylpyruvic acid, m. p. 153—154° [oxime, m. p. 159°, *phenylhydrazone*, m. p. 187—188° (decomp.)], acetone, and carbon dioxide. The *ozonide* of its ethyl ester similarly yields ethyl benzylglyoxylate and ethyl acetoacetate. *trans*- $\alpha$ -Benzyl- $\beta$ -methylglutaconic acid is converted successively into its *ozonide* and acetic acid, phenylethyl methyl ketone, and benzoic acid; the formation of oxalic and glyoxylic acids could not be established. The *ozonide* of ethyl *trans*- $\alpha$ -benzyl- $\beta$ -methylglutaconate is hydrolysed to acetic acid, ethyl acetoacetate, (?) ethyl phenylpyruvate, and benzoic acid.

Ethyl phenylpyruvate is converted into a *diphenylhydrazone*,  $\text{CH}_2\text{Ph}\cdot\text{C}(\text{N}\cdot\text{NPh}_2)\cdot\text{CO}_2\text{Et}$ , small, yellow crystals, m. p. 105°, and a *p*-nitrophenylhydrazone, pale yellow crystals, m. p. 181°. H. W.

**Ring-chain Tautomerism. IV. The Effect of the Methyl Ethyl Grouping on the Carbon Tetrahedral Angle.** BALBIR SINGH and JOCELYN FIELD THORPE (T., 1923, 123, 113—122).

**Composition of Erythrosin.** M. GOMBERG and D. L. TABERN (*J. Ind. Eng. Chem.*, 1922, 14, 1115—1117).—Pure tetraiodofluorescein was prepared by direct halogenation of fluorescein in hot dilute acetic acid with excess of iodine, and subsequent purification by washing with dilute sulphuric acid and alcohol and precipitation from solution in dilute sodium hydroxide. This product did not contain free iodine but was amorphous, and the iodine content was low owing to the presence of about 6% of diiodofluorescein, from which it was purified by conversion, by boiling with acetic anhydride, into the diacetate which, after three recrystallisations from bromobenzene alternated with acetone, was obtained analytically pure and melting at 293—294°. Hydrolysis of the acetate gave pure crystalline tetraiodofluorescein. This was converted into erythrosin by neutralisation with sodium carbonate in suspension in absolute alcohol. The salt was deposited in red

crystals after concentration of the solution and addition of ether. It contained both water and alcohol of crystallisation, and the former was not completely expelled even by long drying at 160—170°. The fully hydrated salt contains  $4\text{H}_2\text{O}$ , and the conclusion seems justified that the true composition of erythrosin is  $\text{C}_{20}\text{H}_6\text{O}_8\text{I}_4\text{Na}_2\cdot\text{H}_2\text{O}$  and that it is almost impossible to dehydrate it beyond this point without risk of decomposition. G. F. M.

**The Semi-pinacolinic Transformation of Alkylhydrobenzoins: Influence of the Alkyl Groups.** MARC TIFFENEAU and ALEX. OREKHOFF (*Compt. rend.*, 1922, 175, 964—967; cf. Meerwein, A., 1920, i, 2; Orekhoff and Tiffeneau, A., 1922, i, 458).—The transformation of alkylhydrobenzoins under the influence of concentrated sulphuric acid may take place in two different ways, yielding either a phenyl  $\alpha$ -alkylbenzyl ketone or a benzhydryl alkyl ketone, and the authors have investigated the influence of the nature of the alkyl group on the relative proportions of the resulting products. The conclusion is drawn that alkyl groups such as methyl, isobutyl, and phenyl, which have a strong "saturation capacity" (Meerwein, *loc. cit.*) yield the former type of product, and conversely. The groups of intermediate "saturation capacity"—ethyl, butyl, propyl, isoamyl—form hydrobenzoins which yield on dehydration mixtures of the two possible products. The results show that the influence of the alkyl group may render the secondary less stable than the tertiary hydroxyl group. This property is evident only in presence of concentrated sulphuric acid, and may result from a temporary linking of the acid with the secondary group. H. J. E.

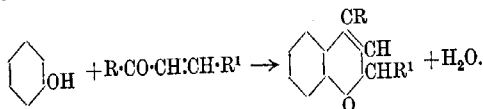

**The Action of Alcohols on Phenyl  $\alpha$ -Bromostyryl Ketone. Formation of Various Saturated and Ethylenic Compounds.**

JH. DUFRAISSE and P. GÉRALD (*Bull. Soc. chim.*, 1922, [iv], 31, 1285—1304).—Phenyl  $\alpha$ -bromostyryl ketone readily unites with alcohols in presence of small quantities of the corresponding sodium alkoxide, giving  $\alpha$ -bromo- $\beta$ -alkoxybenzylacetophenones of the general formula  $\text{COPh}\cdot\text{CHBr}\cdot\text{CHPh}\cdot\text{OR}$ , which can be isolated if the reaction is conducted within suitable narrow limits of temperature, but which when warmed with the reaction mixture, lose hydrogen bromide, giving phenyl  $\beta$ -alkoxystyryl ketones,  $\text{COPh}\cdot\text{CH}\cdot\text{CPh}\cdot\text{OR}$ .

The course of the reaction and the nature of the product initially obtained by Wislicenus (A., 1900, i, 37) by the action of alcoholic potassium hydroxide on phenyl  $\beta$ -bromostyryl ketone, is thus elucidated. The phenyl  $\beta$ -alkoxystyryl ketones are obtained with even greater facility and in purer condition by the addition of alcohol to benzoylphenylacetylene in presence of sodium alkoxide. All attempts to prepare the two stereoisomerides which are theoretically possible in the case of both the saturated and unsaturated compounds, or to prepare derivatives from secondary alcohols or phenols, failed. The preparation and properties of the following compounds are described. Phenyl  $\alpha$ -bromo- $\beta$ -ethoxystyryl ketone,

m. p. 60–61°, b. p. 182–183°/3–4 mm., white crystals, readily decomposed by alkalis and hydrolysed to dibromobenzylacetophenone by hydrobromic acid. *α*-Bromo-*β*-methoxybenzylacetophenone, white crystals, m. p. 76–77°. *α*-Bromo-*β*-propoxybenzylacetophenone, m. p. 95–96°. *α*-Bromo-*β*-butoxybenzylacetophenone, m. p. 81–82°. *α*-Bromo-*β*-isobutoxybenzylacetophenone, m. p. 110–111°. *Phenyl β-ethoxystyryl ketone*, yellowish-white crystals, m. p. 77–78°, b. p. 209°/5 mm., readily hydrolysed to dibenzoylmethane by boiling with 15% alcoholic hydrogen chloride. *Phenyl β-methoxystyryl ketone*, whitish-yellow crystals, m. p. 65–66°. *Phenyl β-propoxystyryl ketone*, m. p. 59–60°. *Phenyl β-butoxystyryl ketone*, a yellow oil, b. p. 204–206°/2 mm. *Phenyl β-isobutoxystyryl ketone*, yellowish crystals, m. p. 55–56°. *Phenyl β-isopropoxystyryl ketone*, crystals, m. p. 49–50°, b. p. 180–183°/2–3 mm. G. F. M.

**Preparation of Condensation Products of  $\alpha\beta$ -Unsaturated Ketones and Phenols.** CHEMISCHE FABRIKEN VORM. WEILERTER MEER (D.R.-P. 357755; from *Chem. Zentr.*, 1922, iv, 890–891).— $\alpha\beta$ -Unsaturated ketones, in the presence of acids, or their acid additive products are condensed with phenols. The reaction in the case of the unsaturated ketones is as follows:

With reactive phenols such as resorcinol or *N*-substituted *m*-amino-phenols the reaction is almost quantitative. The compound from the condensation of phenol and styryl methyl ketone is a grey powder. The compound from resorcinol and styryl methyl ketone is a yellow powder. The compound from the hydrogen chloride additive product of phenyl styryl ketone (3-chloro-1-keto-1:3-diphenylpropane) and resorcinol has a red colour; it forms an acetyl derivative (annexed formula). Other condensation products are formed from phenyl *m*-hydroxystyryl ketone and pyrogallol (brown); from phenyl styryl ketone and pyrogallol (bluish-grey); from phenyl *p*-dimethylaminostyryl ketone and *m*-dimethylaminophenol (greyish-blue); from resorcinol and thiodiketobenzylidenethiazolidine (reddish-brown); from styryl methyl ketone and *p*-cresol (light brown); from *p*-acetamidophenyl *o*-chlorostyryl ketone and quinol (reddish violet). G. W. R.

**Crystallographic Study of  $\alpha\gamma$ -Diketohydrindene.** ANGELO PICCHETTO (*Atti R. Accad. Lincei*, 1922, [v], 31, ii, 143–146).— $\alpha\gamma$ -Diketohydrindene,  $d_{25}^{20}$  1.37, forms crystals belonging to the bipyramidal tetragonal class of the tetragonal system,  $a:c=1:0.9414$ . T. H. P.

***o*-Quinones and 1:2-Diketones. VI.  $\psi$ -Benzils. II. Benzils of the Peroxide Type: 2:2'-Diethoxybenzil, a Derivative of Benzil which is Colourless in Solution.** A. SCHÖNBERG and W. MALCHOW (*Ber.*, 1922, 55, [B], 3746—3752).—In a previous communication (Schönberg and Kraemer, A., 1922, i, 663), the isolation of a number of colourless solid benzils has been described which give more or less intensely coloured solutions.

The superoxide structure,  $\begin{array}{c} \text{O} \cdot \text{CR} \\ | \\ \text{O} \cdot \text{CR} \end{array}$ , has been assigned to the colour-

less, and the diketonic structure to the coloured benzils. This conception is strengthened by the observation that the faintly coloured solutions react less readily than those which are intensely coloured with the usual reagents for 1:2-diketones. In 2:2'-diethoxybenzil, colourless, quadratic leaflets, m. p. 157°, the authors have now found a substance which not only is colourless when solid, but also yields colourless solutions in cold alcohol, acetic acid, benzene, and light petroleum (b. p. 100—110°), which become pale yellow when heated. It melts to a dark yellow liquid which re-solidifies to colourless crystals. It is unimolecular in its colourless solutions, so that the absence of colour cannot be attributed to polymerisation. It is an unusually stable compound which is indifferent to concentrated aqueous ammonia under pressure and is not affected by hydrogen peroxide in acid or alkaline solution. It does not react with naphthylenediamine hydrochloride in boiling glacial acetic acid, but in the presence of boiling dimethylaniline it is slowly converted into 2:3-di-*o*-phenetyl- $\alpha\beta$ -naphthaquinoxaline,

colourless, pointed prisms, m. p. 180°. Similarly, 2:2'-dimethoxybenzil is transformed by *o*-phenylenediamine hydrochloride in the presence of boiling dimethylaniline into 2:3-di-*o*-anisylquinoxaline, colourless, quadratic prisms, m. p. 183°, by 3:4-diaminotoluene hydrochloride into 2:3-di-*o*-anisyl-6-methylquinoxaline, colourless prisms, m. p. 135°, and by naphthalene-1:2-diamine hydrochloride into 2:3-di-*o*-anisyl- $\alpha\beta$ -naphthaquinoxaline, colourless prisms, m. p. 180°. The method of condensation appears to be of general applicability.

2:2'-Dimethoxybenzil is reduced by amalgamated zinc and concentrated hydrochloric acid to  $\alpha\beta$ -di-*o*-anisylethane, m. p. 86° (cf. Späth, A., 1914, i, 1).

4:4'-Diethoxy- $\alpha$ -phenylbenzoin,

colourless needles, m. p. 111°, is prepared by the addition of an ethereal suspension of 4:4'-diethoxybenzoin to an ethereal solution of magnesium phenyl bromide.

3:3'-Dimethoxybenzoin, colourless prisms, m. p. 55°, obtained by the action of potassium cyanide on *m*-methoxybenzaldehyde, is oxidised by Fehling's solution in boiling aqueous alcohol to 3:3'-dimethoxybenzil, yellow prisms, m. p. 83°. The latter substance is converted by *o*-phenylenediamine hydrochloride in the

usual manner into 2:3-di-m-anisylquinoxaline, colourless leaflets, m. p. 110°. H. W.

**o-Quinones and 1:2-Diketones.** VII.  $\psi$ -Benzils. III. Separation of a 1:2-Diketone into its Coloured Crystalline Ketonic and its Colourless Crystalline Peroxide Form. A. SCHÖNBERG and W. BLEYBERG (*Ber.*, 1922, 55, [B], 3753—3758; cf. A., 1922, i, 163, and preceding abstract).—4:4'-Dibenzyl-oxybenzil has been prepared in coloured and colourless forms.

A solution of 4:4'-dihydroxybenzil in absolute alcohol is treated with the calculated quantity of potassium ethoxide and a slight excess of benzyl bromide whereby the diketonic form of 4:4'-dibenzyl-oxybenzil is obtained as dark yellow prisms, m. p. 126°. If the hot, concentrated solution of the dibenzyl ether in alcohol, glacial acetic acid, or light petroleum (b. p. 100—110°) is suddenly cooled by immersion in ice-water, the colourless peroxide variety,  $\text{O}-\text{C}_6\text{H}_4-\text{O}-\text{CH}_2\text{Ph}$ , m. p. about 124° after becoming distinctly yellow at 121°, separates. The success of the isolation depends greatly on the rapidity with which the cooling is effected, so that it is only possible to work with small quantities at a time. A further essential condition is that the mother-liquor should be removed as rapidly as possible, since, although the colourless form is stable when dry, it rapidly passes into the yellow variety when in contact with solvents; this change occurs with such rapidity that the colourless compound appears to yield immediately coloured solutions.

4:4'-Dibenzyl-oxydibenzyl is rapidly converted by hydrogen peroxide in boiling alcoholic solution in the presence of sodium hydroxide into *p*-benzyl-oxybenzoic acid, m. p. 189° (cf. Cohen and Dudley, T., 1910, 97, 1732). It is converted by naphthalene-1:2-diamine hydrochloride in the presence of boiling dimethyl-aniline into the corresponding naphthaquinoxaline,  $\text{C}_{38}\text{H}_{28}\text{O}_2\text{N}_2$ , prisms, m. p. 156°. H. W.

**The Acylamidoanthraquinones as Vat Dyes.** E. GRAND-MOUGIN (*Compt. rend.*, 1922, 175, 970—973).—The introduction of acyl groups into aminoanthraquinones results in the formation of a series of substances the tinctorial characters of which depend on the nature of the substituent entering the amid-group. If a hydroxyl group, which acts as an auxochrome, is present in addition, acetylation or benzylation of this group brightens the colour but usually diminishes the value of the substance as a dye. In the case of  $\alpha$ -benzamidoanthraquinone, the colour is changed from bright yellow to deep rose by the introduction of a hydroxyl group in the para position and to scarlet by a methoxyl group. Further addition of benzamido-groups results in a deepening of the colour. Isomerism influences the colour and, in addition, the tinctorial properties; the author states that no adequate explanation of these facts has yet been put forward. The following substances, all crystalline and of high m. p., were prepared; their colours and the tints they impart to vegetable fibres are noted: 4-Benzamido-

1-hydroxyanthraquinone, red, deep red. 4-Benzamido-1-acetoxyanthraquinone, yellow, rose. 4-Acetamido-1-acetoxyanthraquinone, brownish-red, light brown. 4-Benzamido-1-benzoylanthraquinone, orange-yellow, pale rose. 4-Benzamido-1-methoxyanthraquinone, orange-yellow, scarlet. 4-Acetamido-1-methoxyanthraquinone, orange-yellow, light salmon. 1:4-Diacetamidooanthraquinone, orange-yellow, light brown. 1:4-Dibenzamidooanthraquinone, reddish-yellow, reddish-yellow. 1:5-Dibenzamido-8-hydroxyanthraquinone, red, red. 1:5-Dibenzamido-4:8-dihydroxyanthraquinone, violet-blue, violet-blue. 1:5-Dianisamido-4:8-dihydroxyanthraquinone, violet-blue, violet-blue. 4:5-Dibenzamido-1:8-dihydroxyanthraquinone, violet-blue, light violet. 1:5-Diacetamido-4:8-dihydroxyanthraquinone, orange-brown. 1:5-Diacetamido-4:8-diacetoxyanthraquinone, brownish-yellow. 4:5-Diacetamido-1:8-diacetoxyanthraquinone, reddish-brown. 4:5-Dibenzamido-4:8-diacetoxyanthraquinone, yellowish-brown. The tinctorial colours of the four last-named are not stated. H. J. E.

The Investigation of *meso*-Thioanthracene Derivatives.  
I. Observations on the Production of Dithioanthraquinone, Dithiodianthrone, and Other Closely Related Derivatives.  
ISIDOR MORRIS HEILBRON and JOHN STANLEY HEATON (T., 1923, 123, 173—185).

Condensation Products of Phenylhydroxylamine with Hydroxymethylene Compounds and Carbinols. IV. Methylencamphorphenylhydroxylamine. H. RUPE and W. DIEHL (*Helv. Chim. Acta*, 1922, 5, 906—922).—The reduction of methylenecamphorphenylhydroxylamine to anilinemethylene-camphor (cf. A., 1921, i, 426) can be accomplished by means of sodium hydrogen sulphite in aqueous alcoholic solution. When methylenecamphorphenylhydroxylamine is treated with thionyl chloride in ethereal solution, methylenecamphorphenylchloroamine is formed; it crystallises in short, yellowish-white prisms, m. p. 102—103°. The chlorine appears to be firmly attached to the nitrogen atom; that it has not wandered into the phenyl group was shown by condensing hydroxymethylenecamphor with *p*-chloroaniline, when *p*-chloroanilinomethylenecamphor was obtained, which crystallises in small, white prisms, m. p. 167—169°. Methylenecamphorphenylhydroxylamine combines with 1 mol. of hydrobromic acid to form a hydrobromide,  $C_8H_{14} \begin{smallmatrix} \diagup \\ \text{C} \cdot \text{CH} \\ \diagdown \end{smallmatrix} \text{Br} \cdot \text{NPh} \cdot \text{OH}$ , yellow needles,

m. p. 121° (decomp.). Similarly, it readily combines with bromine in glacial acetic acid solution to form a dibromide, yellow needles, m. p. 117° (decomp.). When the hydroxylamine compound is heated with phenylhydrazine in glacial acetic acid, phenylhydroxylamine is removed and a derivative formed which was found to be identical with the phenylcamphoprazole described by Bishop, Claisen, and Sinclair (A., 1895, i, 634). The formula

is to be preferred to that given by those authors, in which the phenyl group is attached to the 1-nitrogen atom. By the action of semicarbazide on methylenecamphorphenylhydroxylamine, the simple semicarbazone of hydroxymethylenecamphor is formed. Its m. p. is 205–206°, not 217–218° as given by Wallach (A., 1904, i, 106).

The oxidation product of methylenecamphorphenylhydroxylamine obtained by boiling it with cupric acetate (A., 1921, i, 425) can be obtained in much better yield by oxidising in cold alcohol with potassium ferricyanide. It crystallises in monoclinic needles or prisms,  $a : b : c = 0.9971 : 1 : 1.065$ ;  $\beta = 103^\circ 50'$ . Its properties

agree with the double formula,  $\left[ \text{C}_8\text{H}_{14} \begin{array}{c} \text{C}:\text{CH}\cdot\text{N} \begin{array}{c} \text{O} \\ \text{CO} \end{array} \\ \text{Ph} \end{array} \right]_2$ . Its form-

ation requires one atom of oxygen to two molecules of the hydroxylamine. The double molecule takes up four atoms of bromine to form a tetrabromide,  $\text{C}_{34}\text{H}_{40}\text{O}_4\text{N}_2\text{Br}_4$ , which decomposes when heated. When a solution of the tetrabromide in chloroform is warmed, hydrogen bromide is evolved and a compound,

crystallises; white, lustrous aggregates of needles, m. p. 205–208° (decomp.). From the chloroform solution of the tetrabromide a dibromide was also obtained,  $\text{C}_{34}\text{H}_{38}\text{O}_4\text{N}_2\text{Br}_2$ , m. p. 123–126° (decomp.). All these bromo-derivatives are very unstable.

When the above oxidation product of methylenecamphorphenylhydroxylamine is dissolved in 75% sulphuric acid, and then precipitated by dilution, a new compound,  $\text{C}_{34}\text{H}_{44}\text{O}_6\text{N}_2$ , is obtained. It appears to be a hydration product and the formula

is suggested for it. It has no sharp melting point, but sinters from 170°, decomposing at 190–195°. Molecular-weight determinations in different solvents gave very discordant results. It forms a methyl derivative,  $\text{C}_{33}\text{H}_{52}\text{O}_6\text{N}_2$ , m. p. 226–228°. The above formula expresses the fact that the compound is a stronger acid than the parent substance, dissolving readily in barium hydroxide solution.

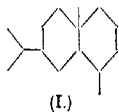

There is a possibility that in the condensation of hydroxymethylenecamphor with phenylhydroxylamine, intramolecular change occurs to give a *p*-aminophenol derivative. This has been disproved by condensing *p*-aminophenol with hydroxymethylenecamphor. The product could not be crystallised, but when methylated with methyl sulphate gave *p*-anisidinomethylenecamphor, white leaflets, m. p. 169–172°. It also gave an acetyl derivative, white leaflets, m. p. 221–223°. E. H. R.

**Action of Sulphur and certain Compounds of Sulphur on Terpenes.** P. F. BUDNIKOV and E. A. SCHILOV (*Ber.*, 1922, 55, [B], 3848–3853; cf. A., 1922, i, 944).—Pinene or mixtures of limonene and silvestrene are converted by prolonged boiling with sulphur into a viscous, reddish-brown liquid from which a homo-

geneous substance could not be isolated by fractional distillation; the percentage of sulphur in the various fractions increases with increasing boiling point. The products yield unstable precipitates when mixed with the chlorides of mercury, gold, or platinum, lead acetate or arsenic iodide in the presence of acetone or alcohol, but these are not suitable for analysis. The action of methyl iodide on the fractions gives *methyl terpenesulphinium iodide*,  $C_{10}H_{16}S,CH_3I$ , a microcrystalline precipitate, m. p. about  $121^\circ$  after previous darkening (the constant is given with reserve by reason of the lack of uniformity of the original material). The substance behaves as a typical sulphinium iodide, and is converted by moist silver oxide into the corresponding *base*. When treated with the theoretically necessary quantity of mercuric iodide in accordance with Smiles's procedure (T., 1900, 77, 163; 1907, 91, 1394), the iodide gives the compounds  $C_{10}H_{16}S,CH_3I,HgI_2$ , pale yellow, microscopic prisms, and  $C_{10}H_{16}S,CH_3I,2HgI_2$ , lemon-yellow prisms, decomp. about  $100^\circ$ . With arsenic tri-iodide, the compound  $C_{10}H_{16}S,CH_3I,AsI_3$ , dark orange-coloured crystals, is produced. The yields of the methiodide are not satisfactory, but it was not found possible to effect any improvement in the initial action by the use of aluminium chloride, mercuric chloride, or mercuric iodide as catalysts. Better results are obtained when sulphur is replaced by sulphur chloride, but the course of the change has not yet been elucidated.

The primary action of sulphur on terpenes appears to consist in the formation of a monosulphide which probably combines with a further quantity of sulphur to give polysulphides. Evidence of the formation of thio-ozonides as suggested by Erdmann has not been obtained. H. W.

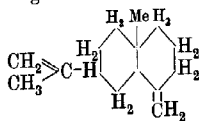

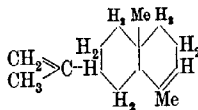

**Higher Terpene Compounds. VII. The Constitution of Eudalene, Selinene, and  $\alpha$ -Santalene. The Carbon Framework of the Sesquiterpenes.** L. RUZICKA and M. STOLL (*Helv. Chim. Acta*, 1922, 5, 923-936; cf. A., 1922, i, 560).—On theoretical grounds, it seemed probable that eudalene is formed from sesqui-

terpene compounds of the type (I) by dehydrogenation and loss of a carbon atom. If this were the case, eudalene should be isomeric with the 2-methyl-8-isopropynaphthalene obtained from cadalene (A., 1922, i, 1001) and should give the same naphthalene-1:7-dicarboxylic acid as this when oxidised with dilute nitric acid. This was found to be the case. *Naphthalene-1:7-dicarboxylic acid* forms a nearly white, amorphous precipitate, sinters from  $200^\circ$ , and melts at  $265^\circ$  to a dark brown liquid. There were also obtained in small quantity a *nitro-2-methyl-8-isopropynaphthalene*, yellow needles, m. p.  $112-113^\circ$ , and a *nitronaphthoic acid*, m. p.  $225-227^\circ$ . The identity of eudalene with 1-methyl-7-isopropynaphthalene was confirmed by synthesis of the hydrocarbon as follows. Cumolol was condensed with ethyl bromoacetate by Reformatsky's method, and from the product ethyl *p*-isopropylcinnamate was obtained.

This was reduced by Bouveault's method giving *p*-isopropylphenyl-propyl alcohol,  $C_3H_7 \cdot C_6H_4 \cdot [CH_2]_2 \cdot CH_2 \cdot OH$ , b. p.  $149^\circ/12$  mm. This was converted through the bromide and cyanide into  $\gamma$ -*p*-cumyl-butyric acid,  $C_3H_7 \cdot C_6H_4 \cdot [CH_2]_3 \cdot CO_2H$ , b. p.  $186^\circ/12$  mm., crystallising in leaflets, m. p.  $31-32^\circ$ . The acid chloride is a mobile oil, b. p.  $156^\circ/12$  mm. When this chloride was treated with aluminium chloride, 8-keto-2-isopropyl-5:6:7:8-tetrahydronaphthalene was obtained, b. p.  $156^\circ/12$  mm. It forms a semicarbazone, m. p.  $195^\circ$ . This was boiled with magnesium methyl iodide, and 1-methyl-7-isopropyl-3:4-dihydronaphthalene was obtained, b. p.  $137^\circ/12$  mm. This was dehydrogenated by heating with the theoretical proportion of sulphur and gave 1-methyl-7-isopropyl naphthalene, identical with eudalene.

The constitution of eudalene having been established, it is shown that the two forms of the sesquiterpene selinene, which readily gives eudalene when treated with sulphur, probably have the following constitutions:

 $\beta$ -Selinene. $\alpha$ -Selinene.

It has now been shown that there are two types of carbon skeleton, in the sesquiterpene series, derived from three isoprene units.

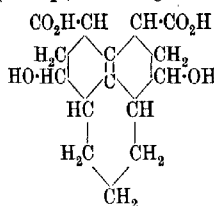

These may be called the cadinene type (II) and the eudesmol type (I). The structure of  $\alpha$ -santalene was determined by Semmler (A., 1910, i, 574), who, however, considered two formulæ possible, belonging to what he called the camphor-type and the camphene-type. It is shown that these two "types" are but different plane projections of the same three-dimensional structure. The structure is definitely related to the eudesmol type (I). It can now be concluded that all known sesquiterpenes are closely related and are derivable from a regular tri-isoprene chain of the kind present in farnesol.

E. H. R.

**The Nature of Shellac. Shellolic Acid.** C. HARRIES and W. NAGEL (*Ber.*, 1922, 55, [B], 3833-3848).—A preliminary account of partly completed work on shellac and sticklac.

The lac is freed from wax and colouring matter by successive treatment with light petroleum and water, and the residue is repeatedly agitated with ether, thereby leaving an insoluble "pure resin" which is the subject of investigation and is the vehicle of the characteristic properties of shellac. The "pure resin" is attacked by *N*-potassium hydroxide solution at the atmospheric temperature, which causes the deposition of *potassium alexisiate*, the amount being 22-24% of the resin taken. The filtrate from the salt is acidified with sulphuric acid and extracted with ether, thus yielding a mixture of shellac resin acids; these are purified

by agitating their ethereal solution with aqueous barium hydroxide and treating the latter with carbon dioxide, when the precipitated barium carbonate adsorbs a portion of the coloured resinous matter. The filtrate contains small amounts of sparingly soluble *barium aleuritate* and the freely soluble barium salts of the shellac resin acids. Attempts to isolate a homogeneous material from the latter by dialysis were not completely successful, but it is shown thereby that the salts are devoid of colour. More rapid but less complete purification can be effected through the zinc salts. The free acids do not crystallise readily. The most satisfactory results are obtained by taking advantage of the observation that the shellac resin acids, unlike other resin acids, are, at any rate in part, esterifiable by methyl-alcoholic hydrogen chloride (3%) at the atmospheric temperature, whereby *methyl shellolate*,  $C_{17}H_{24}O_6$ , long, prismatic rods, m. p.  $149^\circ$ , b. p.  $284-288^\circ/0.1$  mm. (slight decomp.),  $[\alpha]_D^{20} +32.61^\circ$  in methyl-alcoholic solution, is obtained, the amount being 8-10% of the weight of the "pure resin" taken. The ester is hydrolysed by boiling aqueous *N*-sodium hydroxide solution to *shellolic acid* (*shellenedioldicarboxylic acid*), colourless leaflets, m. p.  $199.5-201^\circ$ , decomp.  $202-203^\circ$ , which gives the Liebermann cholesterol and the Salkowski-Hesse reactions. It does not reduce Fehling's solution or decolorise a solution of bromine in chloroform; its unsaturated nature is demonstrated by its instability towards alkaline permanganate and the apparent formation of an *ozonide*. The *sodium* and *barium* salts are colourless, amorphous, and freely soluble in water; the *silver*, *copper*, and *lead* salts dissolve more sparingly. The *hydrazide*,  $C_{15}H_{24}O_4N_4$ , crystallises in well-defined prisms, m. p.  $243-244^\circ$  (decomp.); the non-crystalline *acetyl* derivative and the *diphenyldiurethane*,  $C_{21}H_{34}O_8N_2$ , m. p.  $92-94^\circ$  (decomp.) according to the rate of heating, are described. The

annexed formula for shellolic acid is suggested tentatively; the positions of the hydroxyl and carboxyl groups cannot yet be definitely assigned. The position of the double bond accounts for the inactivity of the acid towards bromine.

The non-crystalline residue of esters from which methyl shellolate has been separated (*v.s.*) has b. p.  $180-210^\circ/0.1$

mm., and appears to consist of compounds of hydroxy-acids. The latter are themselves amorphous, but give solid phenylurethanes.

The investigation has rendered it very improbable that shellac resin is the aleuritic ester of a higher alcohol, since no trace of the latter could be detected and it must be present in considerable quantity if it were an actual constituent. Since it is established that the resin does not contain a free acid, it appears probable that the shellac molecule is composed of hydroxy-acids which are united in the form of lactides. For one of the simpler components, the constitution  $\text{CO} > \text{C}_{13}\text{H}_{16}(\text{OH})\text{CO}\text{O}\text{C}_{15}\text{H}_{28}(\text{OH}) < \text{CO}$  is sug-

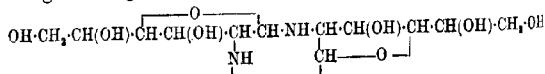

gested, the composition of which is very similar to that of the "pure resin."  
H. W.

**Centaureidin, a Decomposition Product of Centaurein, the Glucoside of Roots of *Centaurea Jacea*.** M. BRIDEL and G. CHABAUX (*Compt. rend.*, 1922, **175**, 1168—1170).—Centaureidin,  $C_{18}H_{16}O_8$  (this vol., i, 50), crystallises from 50% alcohol in microscopic, yellow needles containing water of crystallisation which is lost at 50°. The crystals melt at 197°, the anhydrous substance at 203°. It is insoluble in water, but dissolves in many organic solvents. With aqueous alkalis or sulphuric acid, it gives a golden-yellow solution. As the result of a general study of its properties, the authors suggest that it may be a flavone derivative, although the evidence on behalf of such a conclusion is mainly negative.  
H. J. E.

**Polysaccharides. XVII. Chitin.** P. KARRER and ALEX. P. SMIRNOV (*Helv. Chim. Acta*, 1922, **5**, 832—852).—To determine how the glucosamine residues are combined in chitin, a study was made of the decomposition products obtained when chitin was distilled with zinc dust. From 300 g. of chitin from lobster shells, 37 g. of a brown oil were obtained which consisted chiefly of pyrrole compounds with a small quantity of pyridine bases, among which  $\alpha$ -picoline was identified. From the mixture of pyrrole compounds a fraction was isolated which was identified as 2-methyl-1-*n*-hexylpyrrole. This compound and 2:5-dimethyl-1-*n*-amylpyrrole were synthesised for comparison with the compound from chitin, to which the name chitopyrrole is applied.

2:5-Dimethyl-1-*n*-amylpyrrole was prepared by heating acetonol-acetone with *n*-amylamine. It is a colourless oil, b. p. 225—227°, with an orange-like odour, and gives a cherry-red, pine-shaving reaction. 2-Methyl-1-*n*-hexylpyrrole was prepared from potassium 2-methylpyrrole and *n*-hexyl iodide. It is a colourless oil, rapidly turning brown, b. p. 200—210°, smelling like old fungus, and gives an intense red, pine-shaving reaction. Chitopyrrole boils over a somewhat wider range than 2-methyl-1-*n*-hexylpyrrole, 190—220°, but essentially the two appear to be identical. Both are oxidised by chromic or nitrous acid to a substituted maleinimide, which when hydrolysed gives maleic acid and *n*-hexylamine. The last was identified by preparation of the *picrolonate*, m. p. 188—189°, which was also prepared from synthetic *n*-hexylamine.

The formation of 2-methyl-1-*n*-hexylpyrrole from chitin indicates the presence in the latter of two glucosamine residues combined through a nitrogen atom as in the following formula:

Neither the position of the acetyl groups nor the number of glucosamine residues present in the molecule can yet be stated. Chitosan, which is formed from chitin by hydrolytic removal of the acetyl groups, is converted by nitrous acid into a reducing sugar with

total loss of its nitrogen in the elementary form. This behaviour is quite in accordance with the above representation of chitin as an aldehyde-ammonia derivative.

E. H. R.

**Betulin.** OTTO DISCHENDORFER (*Ber.*, 1922, 55, [B], 3692—3693).—A preliminary account of the author's observations induced by the recent publication of Schulze and Pieroh (*A.*, 1922, i, 1045).

*Monobromobetulin*, m. p. 215°, and the corresponding *diacetate*, m. p. 193°, have been prepared. Analyses of the latter indicate the possibility of the formulae  $C_{30}H_{48}O_2$  or  $C_{36}H_{50}O_2$  for betulin, whereas Schulze and Pieroh (*loc. cit.*) regard  $C_{32}H_{52}O_2$  or  $C_{33}H_{54}O_2$  as probable.

H. W.

**Strophanthin. I. Strophanthidin.** WALTER A. JACOBS and MICHAEL HEIDELBERGER (*J. Biol. Chem.*, 1922, 54, 253—261).—When dried in a vacuum at 110° over phosphoric oxide, strophanthidin decreases in weight by an amount corresponding with the loss of  $\frac{1}{2}H_2O$ . The anhydrous substance therefore has the formula  $C_{23}H_{33}O_6$ . The loss of  $1\frac{1}{2}H_2O$  noted by Windaus and Hermanns (*A.*, 1915, i, 704, 705) was evidently due to partial decomposition. A final decision between the  $C_{23}$  formula and the  $C_{27}$  formula of Feist is rendered possible by the preparation of the *p-bromobenzoate*,  $C_{30}H_{35}O_7Br.H_2O$ . In the anhydrous condition this compound has m. p. 222—224° (decomp.),  $[\alpha]_D^{25} + 42^\circ$  in acetone. Strophanthidin (strophanthidinic acid lactone of Feist, *isomymarigenin* of Windaus and Hermanns) has the same formula as trophanthidin, crystallises with  $\frac{1}{2}H_2O$ , and forms a *benzoate*,  $C_{30}H_{35}O_7$ , rosettes of microscopic leaflets, m. p. about 270° after intering,  $[\alpha]_D^{25} + 38.0^\circ$  in chloroform. When reduced with hydrogen in the presence of colloidal palladium, strophanthidin slowly absorbs two atoms of hydrogen with the formation of *dihydrostrophanthidin*,  $C_{23}H_{34}O_6$ , which melts at 190—195° when anhydrous and crystallises with one or two molecules of water, according to the method of crystallisation. The dihydrate has  $[\alpha]_D^{25} + 34.85^\circ$  in methyl alcohol. Dihydrostrophanthidin forms a *benzoate*,  $C_{30}H_{38}O_7$ , minute, glistening prisms, m. p. 225—227° (decomp.). The presence of a carbonyl group in strophanthidin is shown by the preparation of the *oxime*,  $C_{23}H_{33}O_6N$ , glistening prisms, m. p. 270—275° (decomp.),  $[\alpha]_D^{25} + 71.3^\circ$  in pyridine, the *phenylhydrazone*,

glistening prisms, m. p. 230—232° after sintering at 175°,  $[\alpha]_D^{25} - 5.0^\circ$  in chloroform, and the *p-bromophenylhydrazone*,

pointed prisms which soften at 180—185° and become completely molten at 200°, and have  $[\alpha]_D^{25} + 105.5^\circ$  in chloroform.

E. S.

[**Catechin.**] M. NIERENSTEIN (*Ber.*, 1922, 55, [B], 3831—3833).—A reply to Freudenberg (*A.*, 1922, i, 756).

The author maintains that catechin-carboxylic acid can be prepared according to his method, and promises further details with regard to Kostanecki's catechone. With respect to the production

of optically active catechin from inactive catechin-carboxylic acid, the inactivity of the latter is maintained, but the optical activity of Gambier catechin is not considered to be established. Pure Gambier- and aca-catechins are not precipitated by solutions of gelatin. Freudenberg's observation that tetramethylcatechin cannot be demethylated by the author's method is correct so far as the derivative of Gambier catechin is concerned, but is not true for that of aca-catechin. The identity of the methylated product of the reduction of catechin with pentamethoxy- $\alpha$ -diphenylpropane is not regarded as established. The homogeneity and optical inactivity of aca-catechin, m. p. 204—205°, is maintained.

H. W.

**Tannins and Similar Compounds. XII. The Tannin of the Native [German] Oak.** KARL FREUDENBERG and ERICH VOLLBRECHT (*Annalen*, 1922, 429, 284—317).—A more expanded account of work already published (cf. A., 1922, i, 1046).

C. K. I.

**Constitution of Thiophen.** WILHELM STEINKOPF [with HALVARD AUGESTAD-JENSEN and HANS DONAT] (*Annalen*, 1922, 430, 78—112).—The lability of the hydrogen atoms in the thiophen nucleus is well illustrated by its behaviour towards cyanogen bromide, with which it reacts analogously to compounds of the type of ethyl acetoacetate and ethyl malonate, which are known to contain labile hydrogen.

Thus ethyl acetoacetate and cyanogen bromide react, giving ethyl  $\gamma$ -bromoacetoacetate. Ethyl malonate yields ethyl bromo-malonate. Acetophenone yields  $\omega$ -bromoacetophenone, and in a similar way 2-acetothienone yields  $\omega$ -bromo-2-acetothienone. Phenol and cyanogen bromide yield *p*-bromophenol, whilst indene and cyanogen bromide give 1-bromo-2-hydroxyhydrindene.

Thiophen reacts with cyanogen bromide, giving bromothiophen, b. p. 151—151.5°, and dibromothiophen, b. p. 195—206°, and with cyanogen iodide, giving 2-iodothiophen (identified as the 5-iodo-2-mercurichloride). Bromothiophen is converted by cyanogen bromide into dibromothiophen, and 2-thiotolen into bromo-thiotolen, b. p. 173—177°.

Alkylthiophens in which both  $\alpha$ -positions are substituted are also brominated by cyanogen bromide. 2:5-Dipropylthiophen yields 3-bromo-2:5-dipropylthiophen, b. p. 130—132.5°/10 mm., and 2-ethyl-5-isoamylthiophen yields 3-(or 4)-bromo-2-ethyl-5-isoamylthiophen, b. p. 122—127°/14 mm.

The above 2:5-dialkylthiophens were synthesised by way of the corresponding ketones. 5-Ethyl-2-propiothienone, b. p. 137—138°/19 mm., prepared from 2-ethylthiophen, propionyl chloride, and phosphoric oxide, gives a semicarbazone, m. p. 195—196°, and on reduction with zinc and hydrochloric acid gives 2-ethyl-5-propylthiophen, b. p. 196—197°. 5-Propyl-2-propiothienone, b. p. 137—138.5°/13 mm., prepared from 2-propylthiophen, propionyl chloride, and either phosphorus pentoxide or aluminium chloride, yields a semicarbazone, prisms, m. p. 174—175°, and on reduction

gives 2:5-dipropylthiophen, b. p. 213—214°. 5-isoAmyl-2-acetothienone, b. p. 149—151°/13 mm., prepared from 2-isoamylthiophen, acetyl chloride, and phosphorus pentoxide, gives a semicarbazone, leaflets, m. p. 212°, and on reduction yields 2-ethyl-5-isoamylthiophen, b. p. 103.5—106.5°/12 mm. None of these 2:5-dialkylthiophens gives well characterised mercury compounds on treatment with mercuric chloride. C. K. I.

**The Thiophen Series. XV. Cyclic Mercury Compounds, and Experiments on the Formation of Mixed Thiophen-Mercury Compounds.** WILHELM STEINKOPF, WILHELM BIELENBERG, and HALVARD AUGESTAD-JENSEN (*Annalen*, 1922, **430**, 40—78).—The experiments carried out with the object of preparing the mixed mercury compound,  $C_6H_5S\cdot HgPh$ , were based on the reaction between magnesium phenyl bromide and phenyl mercurichloride, the products of which are mercury diphenyl and magnesium chloride and bromide. Pure mercury phenyl thienyl could not be isolated from the product of the action of magnesium phenyl bromide in 2-thienylmercurichloride, although evidence of its formation was obtained. Mercury diphenyl is also formed by the action of mercurous chloride on magnesium phenyl bromide, and by the action of stannous chloride on magnesium phenyl chloride. Similarly, mercury 2:2'-dithienyl is the product of the reduction of thienyl-2-mercurichloride by stannous chloride.

A series of cyclic mercury-thiophen compounds is described of which dimercury 2:2':5:5'-dithienylene,  $\begin{array}{c} CH_3C-Hg-C_6H_5 \\ | > S S < | \\ CH_3C-Hg-C_6H_5 \end{array}$ , is

typical. This substance is obtained from 2:5-thienylenedimercurichloride and either sodium iodide or sodium thiocyanate in the presence of pyridine. Pyridine and mercuric chloride convert it into mercury 5:5'-dithienylene-2:2'-dimercurichloride, which may also be obtained by the action of pyridine on thienylene-2:5-dimercurichloride. Dimercury 3:3'-(or 4:4')diethyl-2:2':5:5'-dithienylene, mercury diethyl-5:5'-dithienylene-2:2'-dimercurichloride, and dimercury 3:4:3':4'-tetramethyl-2:2':5:5'-dithienylene are also described; like the unalkylated parent substances, they are all exceedingly insoluble compounds which do not melt at 320°. Dimercury diethyldithienylene, on treatment with mercuric chloride under regulated conditions, yields mercury diethyldithienylene-dimercurichloride, but excess of the reagent effects complete disruption of the molecule, the product being 3-ethylthienylene-2:5-dimercurichloride.

A colorimetric method of estimating the rate of separation of mercuric sulphide when an organic mercury compound is treated with sodium sulphide is described in the original. C. K. I.

**Synthesis of Substituted Thianthrens. I. Thianthren and Nitrothianthren.** SRI KRISHNA (T., 1923, **123**, 156—160).

**Production and Reactions of 2-Dithiobenzoyl.** MARY McKIBBEN and ERNEST WILSON McCLELLAND (T., 1923, **123**, 170—173).

**The Alkaloids of the Northern Aconite (*Aconitum septentrionale*, Koelle).** GUNNAR WEIDEMANN (*Arch. exp. Path. Pharm.*, 1922, 95, 166—180).—Two alkaloids, isolated from the northern aconite, have been investigated. Lappaconitine,

$C_{32}H_{42}O_9N_2$ , forms hard, glass clear, six-sided prisms, m. p.  $223^\circ$ ,  $[\alpha]_D^{25} + 27.4^\circ$  in chloroform. It is a monoacid base, and contains three methoxyl groups. It forms a *chloroplatinate*,  $C_{32}H_{42}O_9N_2 \cdot HPtCl_5$ , and a *chloraurate*,  $C_{32}H_{42}O_9N_2 \cdot HAuCl_4$ . On hydrolysis with alcoholic potash, it yields lappaconitic acid,  $C_8H_9O_3N$ , shown to be acetyl anthranilic acid, and a base lappaconine,  $C_{23}H_{35}O_7N \cdot 2H_2O$ , m. p.  $93^\circ$ ,  $[\alpha]_D^{25} + 22.41^\circ$ . It forms a *hydrochloride*,  $C_{23}H_{35}O_7N \cdot HCl$ , large, colourless crystals. Septentrionaline,  $C_{29}H_{34}O_6N_2(OMe)_4$ , the other alkaloid investigated, is an amorphous, white powder, m. p.  $131^\circ$ ,  $[\alpha]_D^{25} + 32.71^\circ$ , forming a *chloroplatinate*,  $C_{29}H_{34}O_6N_2 \cdot HPtCl_5$ . On hydrolysis with alcoholic potash, there is obtained (1) an acid,  $C_8H_9O_3N$ , m. p.  $125$ — $126^\circ$ , which when boiled with sodium hydroxide solution yields anthranilic acid, losing  $CH_2O$ , and (2) a base,  $C_{25}H_{33}O_7N$ , m. p.  $89^\circ$ ,  $[\alpha]_D^{25} + 29.55^\circ$ , forming a *hydrochloride*,  $C_{25}H_{33}O_7N \cdot HCl$ .  
W. O. K.

**Paniculatine, the Alkaloid from *Aconitum paniculatum*, Lam.** G. E. BRUNNER (*Schweiz. Apoth. Zig.*, 1922, 60, 357—358; from *Chem. Zentr.*, 1922, iii, 1007).—Paniculatine,  $C_{29}H_{35}O_7N$ , the alkaloid from *Aconitum paniculatum*, Lam., is not identical with aconitine. It forms small, rhombic prisms with m. p.  $263^\circ$ .  
G. W. R.

**Melanins, Arising from Adrenaline.** PIETRO SACCARINI (*Biochem. Z.*, 1922, 132, 439—442).—Melanin-like pigments, obtained by the oxidation of adrenaline with chlorine water, are described.  
W. O. K.

**Preparation of a Quinine Derivative.** AKTIEN-GESellschaft FÜR ANILIN-FABRIKATION, JULIUS ALTSCHUL, and MARCELL BACHSTEZ (D.R.-P. 357753; from *Chem. Zentr.*, 1922, iv, 951).—Equimolecular amounts of quinine and 4-ethoxyphenylmalonamic acid are fused together and crystallised from hydrolysing solvents or allowed to react as such or in form of their salts in the presence of hydrolysing solvents. *Quinine 4-ethoxyphenylmalonamate* forms long, colourless needles, m. p.  $72$ — $73^\circ$ .  
G. W. R.

**Quiteninone.** SIGMUND FRÄNKEL, CHARLOTTE TRITT-ZIEMING and LILY GOTTESMANN-GRAUER (*Ber.*, 1922, 55, [B], 3931—3935).—The action of hydrogen peroxide (30%) on a solution of quinine sulphate in dilute sulphuric acid in the presence of copper or ferric sulphate as catalyst and at the atmospheric temperature leads to the production of *quiteninone*,  $C_{19}H_{20}O_4N_2$ , needles, m. p.  $156^\circ$ . The reaction appears to be considerably influenced by external factors and to take place through a number of intermediate products of which quinine oxide (cf. Speyer and Becker, A., 1922,

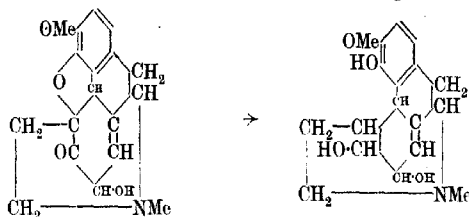

i, 674) is one. Quiteninone is also produced by the oxidation of quitenine (cf. Nierenstein, A., 1920, i, 875). It gives a *picrate*, m. p. 140°. The constitution of quiteninone is partly elucidated by the preparation of the *methyl ester picrate*,  $C_{20}H_{22}O_4N_3 \cdot 2C_6H_3O_7N_3$ , decomp. 270°, and the *methyl ester dihydrochloride*, m. p. 181°. Quiteninone could not be caused to react with phenylhydrazine, *p*-nitrophenylhydrazine, or semicarbazide hydrochloride; with hydroxylamine in alkaline solution, it gives an oxime which is identified as the corresponding *picrate*,  $C_{19}H_{21}O_4N_3 \cdot C_3H_3O_7N_3$ , m. p. 126°. H. W.

**Esterification of Creatine.** ARTHUR W. DOX and LESTER YODER (*J. Biol. Chem.*, 1922, 54, 671—673).—Saturation of a suspension of creatine in an alcohol with hydrogen chloride results in the formation, not of creatinine, but of an ester of creatine the hydrochloride of which separates on the addition of ether. By this means the author has prepared: *creatine methyl ester hydrochloride*, slender needles, m. p. 139—140°; *creatine ethyl ester hydrochloride*, needles, m. p. 163°; *creatine n-butyl ester hydrochloride*, flat needles, n. p. 138°. Each salt melts with the evolution of gas and leaves a solid residue of creatinine hydrochloride. E. S.

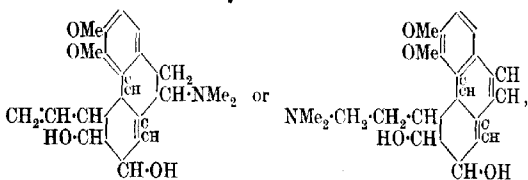

**Ergot.** A. STOLL (*Schweiz. Apoth. Ztg.*, 1922, 60, 341—346; *from Chem. Zentr.*, 1922, iii, 1007; cf. Spiro and Stoll, A., 1922, 47).—The specific effect of ergot is not considered to be due to the presence of simple amines such as tyramine. After addition of acid reagents such as aluminium sulphate to ergot, extraction of one kg. of the material with ether and benzene removes 350—400 g. of alkaloid-free ergot oil together with soluble acid and neutral substances such as organic acids, phytosterol, and colouring matters. From the acidified cell material a crystalline alkaloid was separated. *Ergotamine*,  $C_{33}H_{35}O_5N_5 \cdot 2COMe \cdot 2H_2O$  (from acetone) forms highly refractive rhombic prisms; it has  $[\alpha]_D^{25} -155^\circ$  in 0.6% chloroform solution; the monoacid base and its compounds decompose on heating at 140°; at 180° a brown mass is formed with evolution of gas. On keeping an ethyl-alcoholic solution or warming a methyl-alcoholic solution of ergotamine, an isomeride, *ergotaminine*, of weaker basic character, is formed. It crystallises in triangular leaflets and has  $[\alpha]_D^{25} +381^\circ$  in 0.6% chloroform solution. Ergotaminine may be reconverted into ergotamine. Both isomerides give a blue coloration with strong sulphuric acid. Ergotamine is unstable in air. G. W. R.

**The Hydroxycodeinone Series.** EDMUND SPEYER [with S. SELIG and MARTIN HEIL] (*Annalen*, 1922, 430, 1—40).—A further account (see A., 1915, i, 580; 1916, i, 157, 758; 1921, i, 685) of derivatives of codeine and thebaine including the reduction of hydroxycodeinone to hydroxythebainol and the conversion of the latter into a nitrogen-free substance by exhaustive methylation. All results are interpreted on the basis of Knorr's formula for morphine.

Hydroxycodeinone is converted either by electrolytic reduction or by zinc and formic acid into *hydroxythebainol*, m. p. 234° :

the *formate* of hydroxythebainol, m. p. 227°, and 7-hydroxycodeine being obtained as by-products in the latter case. Hydroxythebainol yields a crystalline *hydrochloride*, *hydrobromide*, m. p. 252—253°,  $[\alpha]_D^{20} -157.7^\circ$ , *hydriodide*, m. p. 247°, and *picrate*, m. p. 204—206°. On treatment with benzoyl chloride, it gives a *benzoyl* derivative, needles, m. p. 257°; with bromine and acetic acid, a *perbromide*, which on reduction by sulphur dioxide gives a *mono-bromo-derivative*, m. p. 230—231°, reducible to hydroxythebainol, and with hydrogen peroxide an *N-oxide*, which crystallises in prisms, m. p. 237°. On methylation with methyl sulphate and alkali, hydroxythebainol yields the *methyl ether methiodide*, rhombs, decomp. 233°, which with hot alkali hydroxide gives des-N-methylhydroxythebainol methyl ether,

small needles, m. p. 195—197°. The *hydriodide* forms needles, m. p. 255°, and the *methiodide*, obtained with the aid of methyl iodide, microscopic prisms, decomp. 239—240°. On treating this substance successively with silver oxide and concentrated alkalis, trimethylamine is eliminated and the nitrogen-free substance, 2 : 3-dihydroxy-5 : 6-dimethoxy-4-vinyl-2 : 3 : 4 : 4a-tetrahydrophenanthrene, is obtained. This forms stout prisms, m. p. 188—189°, and is insoluble in alkali, which shows that the two hydroxyl groups are in the aliphatic part of the molecule.

An improved method of preparation of hydroxythebainone is described. Its *dibromide*, obtained by the use of bromine and chloroform, decomposes at 258°, and on reduction by hydrogen and palladium black gives hydroxydihydrothebainone, which may be obtained directly from hydroxythebainone by means of the same reducing agent. The *methiodide* of hydroxythebainone forms prisms, m. p. 245°, the *acetyl* derivative, needles, m. p. 197°, and

he *oxime* of the acetyl derivative, prisms, m. p. 216–218°. The *nethiodide* of the acetyl derivative decomposes at 212–213°, and gives a non-crystalline *deoxy-base* on decomposition by alkalis. The *nethiodide* of the acetyl derivative of 7-hydroxycodeine sinters at 230° and decomposes at 256°.

Reduction of hydroxycodeinone oxime by hydrogen and palladium under various conditions yielded hydroxydihydrocodeinone, and it was not found possible to prevent the elimination of the oximino-group. Parallel experiments with styrylmethylketoxime and distyrylketoxime yielded analogous results, the products being benzylacetone and dibenzylacetone, respectively. C. K. I.

**The Pilocarpine Series. II. Pilocarpic Esters and their Derivatives.** MAX POLONOVSKI AND MICHEL POLONOVSKI (*Bull. Soc. chim.*, 1922, [iv], 31, 1185–1201; cf. this vol., i, 52).—Although it is generally accepted that a  $\gamma$ -lactone group is present in pilocarpine and its isomeride, few of the properties of a  $\gamma$ -lactone have been actually shown to be characteristic of these substances. The authors find that the esterification of pilocarpine by means of methyl or ethyl alcohol and hydrogen chloride does not yield the ethyl ester of pilocarpic acid but the ethyl  $\gamma$ -chloro-ester, thus confirming the  $\gamma$ -lactone grouping by the characteristic reaction of simultaneous esterification of acidic and alcoholic groups by alcohol and halogen, respectively. *Methyl  $\gamma$ -chloropilocarpate* forms small, transparent prisms, m. p. 42–44°,  $[\alpha]_D + 32.6^\circ$ , and is a strong base; the *nitrate* forms lustrous plates, m. p. 157°,  $[\alpha]_D + 20^\circ$ . *Ethyl  $\gamma$ -chloropilocarpate* was obtained as an oil,  $[\alpha]_D + 29.2^\circ$ ; the *nitrate* forms lustrous plates, m. p. 136°,  $[\alpha]_D + 23.4^\circ$ . On treatment of the nitrate with concentrated sulphuric acid, it is converted into ethyl  $\gamma$ -chloronitropilocarpate. The  $\gamma$ -chloro-esters of pilocarpine are readily relactonised with loss of the halogen atom and the alkyl group; this is accompanied by the transformation of a portion of the alkaloid into its isomeride. *isopilocarpine* behaves in a similar manner to pilocarpine on esterification. *Methyl  $\gamma$ -chloroisopilocarpate* is an oil of very alkaline reaction,  $[\alpha]_D - 7.5^\circ$ , *nitrate*, hygroscopic crystals, m. p. about 100°,  $[\alpha]_D - 5.6^\circ$ ; the *ethyl* ester is also an oil,  $\alpha_D - 5^\circ$  (*nitrate*, crystalline, m. p. 95°,  $[\alpha]_D 0$ ). All these chloro-esters are unstable, even in the solid state at the ordinary temperature, a portion of the substance being transformed into the hydrochloride of a quaternary base. The chloro-esters react readily with sodium ethoxide or methoxide, yielding an oily mixture of the ethyl esters of  $\alpha$ - and  $\beta$ -anhydropilocarpic acids, separable by the difference in solubility of their nitrates in water.  *$\alpha$ -Anhydropilocarpic acid*,  $C_{11}H_{16}O_2N_2$ , forms lustrous plates, m. p. 243°,  $[\alpha]_D - 19^\circ$ ; the *hydrochloride* has m. p. 187°; the *ethyl ester* is an oil and yields a *nitrate*, colourless needles, m. p. 165°,  $[\alpha]_D - 19^\circ$  in alcohol and  $+3.4^\circ$  in water.  *$\beta$ -Anhydropilocarpic acid* forms prismatic crystals, m. p. 186°,  $[\alpha]_D + 42^\circ$ ; the *hydrochloride* has m. p. 142°; the *ethyl ester* forms large, transparent tablets, m. p. 48°, and gives a *nitrate*, m. p. 95°,  $[\alpha]_D - 28^\circ$  in water.

On bromination, ethyl  $\alpha$ -anhydropilocarpate gives a *bromo-derivative*,  $C_{13}H_{19}O_2N_2Br$ , from which on hydrolysis the *bromo-acid*, m. p.  $139^{\circ}$ — $139^{\circ}$ , is obtained.

The formulæ  $CH \begin{smallmatrix} \diagup NMe \cdot CH \\ \diagdown N - C \cdot CH_2 \cdot CH \end{smallmatrix} \begin{smallmatrix} CH_2 \\ CH \end{smallmatrix} > CEt \cdot CO_2H$  and

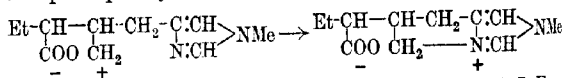

are suggested as possible for the isomeric acids.

H. J. E.

**The Pilocarpine Series. III. *iso*Pilocarpinanil or Phenyl-isopilopyrrolidone.** MAX POLONOVSKI and MICHEL POLONOVSKI (*Bull. Soc. chim.*, 1922, [iv], **31**, 1201—1204; cf. preceding abstract).—Pilocarpine combines with aromatic amines yielding very stable pyrrolidone compounds. This reaction points to the existence of a lactone group in pilocarpine (cf. Emmert and Meyer, A., 1921, i, 268). The same substances may be obtained from the  $\gamma$ -halogen acids derived from the alkaloid. Prolonged heating being necessary, the products are derivatives of *isopilocarpine*. *isoPilocarpinanil* is a hard substance, slightly alkaline in reaction, which gives with mineral acids crystalline salts of acid reaction. The *nitrate*, colourless plates, m. p.  $162^{\circ}$ ,  $[\alpha]_D + 21.2^{\circ}$ , and the *hydrochloride*, white, hygroscopic prisms, m. p.  $135^{\circ}$ , were prepared. The base yields on nitration a substance containing a nitro-group in the benzene ring, which was not further investigated. H. J. E.

**The Pilocarpine Series. IV. Metapilocarpine.** MAX POLONOVSKI and MICHEL POLONOVSKI (*Bull. Soc. chim.*, 1922, [iv], **31**, 1204—1208; cf. preceding abstracts).—As substances obtained by the authors from the decomposition of  $\gamma$ -chloro-esters of pilocarpine seemed to be identical with the metapilocarpine described by Pinner (A., 1905, i, 658), it appeared that the latter could not be a simple stereoisomeride. An examination of its properties resulted in confirmation of Pinner's observations. The substance is inactive towards polarised light, and, although neutral to litmus and giving with acids salts of acid reaction, does not combine with alkalis. Its reactions lead to the conclusion that in metapilocarpine the lactone grouping is absent and the acid group which replaces it is neutralised either by the basic glyoxaline ring or by a betaine linking,  $CO-O-N$ . The authors prefer the second explanation, and therefore represent the transformation of pilocarpine into metapilocarpine by

H. J. E.

**The Pilocarpine Series. V. Isomerism of Pilocarpine and *iso*Pilocarpine.** MAX POLONOVSKI and MICHEL POLONOVSKI (*Bull. Soc. chim.*, 1922, [iv], **31**, 1314—1330).—The authors discuss the evidence for and against the various hypotheses advanced

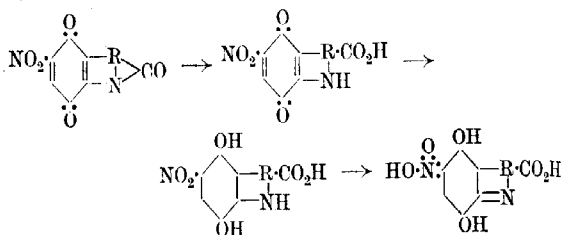

to account for the isomerism of pilocarpine and *isopilocarpine*, and reject as untenable theories based on position isomerism in favour of stereoisomerism arising in or near the lactonic group. Their conclusions are largely based on the isomerisation of pilocarpine and its derivatives to *isopilocarpine* and its corresponding derivatives by action of small quantities of sodium ethoxide on alcoholic solutions of the alkaloid in the cold. It was found that pilocarpine and nitropilocarpine were completely isomerised under these conditions by traces of sodium ethoxide, that molecular quantities of sodium ethoxide gave an isomerised and delactonised product, the de-lactonisation proceeding much more slowly than the isomerisation and requiring twenty-four to forty-eight hours for completion, and that sodium pilocarpate, sodium nitropilocarpate, and ethyl chloropilocarpate were not isomerised to the *iso*-derivatives; in other words, esterification or salt formation causes a stabilisation of the pilocarpine molecule, whence it is concluded that for isomerisation by sodium ethoxide the presence of the unchanged lactone grouping is essential, and this group is probably the seat of the isomerism. Whilst the nature of the stereoisomerism must for the present be left an open question, the authors incline to the view that it may be a case of partial racemisation of one of the two asymmetric C atoms of the lactonic group in view of the similarity between the isomerism of pilocarpine and that of hyoscyamine.

**Strychnos Alkaloids. XXXV. Ethers of Hydroxydihydrobrucinolone and the Violet Colour Reaction of the Nitroquinones obtained therefrom.** HERMANN LEUCHS, JOHANNES GRÜSS, and HARRY HEERING (*Ber.*, 1922, 54, [B], 3729—3738; cf. A., 1921, i, 883).—The action of boiling methyl-alcoholic potassium hydroxide solution on brucinolone or its acetyl derivative leads to the formation of small amounts of *methoxydihydrobrucinolone*,  $C_{22}H_{26}O_6N_2 \cdot 3H_2O$ , coarse prisms or plates, m. p.  $82^\circ$ ,  $[\alpha]_D^{25} -50.3^\circ$  in glacial acetic acid solution, and (mainly) a product, m. p.  $200-202^\circ$  after softening at  $190^\circ$ , which is converted by acetic anhydride into acetylmethoxydihydrobrucinolone,  $C_{24}H_{28}O_7N_2$ , m. p.  $258-270^\circ$ ,  $[\alpha]_D^{25} -92.5^\circ$ , in glacial acetic acid solution, and acetylcryptobrucinolone. Attempts to separate the mixture, m. p.  $200-202^\circ$ , into its components by methyl-alcoholic ammonia at  $100^\circ$  were unsuccessful. Under these conditions, cryptobrucinolone is converted into a base,  $C_{21}H_{25}O_5N_3$  (isolated as the hydrochloride), identical with that isolated previously, but in much poorer yield, from crude acetylbrucinolone and ammonia (Leuchs, A., 1914, i, 317); its formation in the latter instance appears to depend on the presence of cryptobrucinolone or its ester in the acetylbrucinolone. It unites with phenylcarbimide to give the compound  $C_{28}H_{30}O_6N_4$ , small prisms, m. p.  $200^\circ$ .

Ethoxydihydrobrucinolone is converted by 5*N*-nitric acid at  $0^\circ$  into the corresponding *quinone*, a yellowish-red resin which yields a *semicarbazone*, slender, orange-coloured needles, m. p.  $240^\circ$  after change at  $211^\circ$ . The free quinone is reduced by sulphur dioxide

to a colourless, amorphous product; the corresponding acetate could not be caused to crystallise. The action of 5*N*-nitric acid on ethoxydihydrobrucinolone at 50–60° leads to the formation of the *nitroquinone hydrate*,  $C_{21}H_{25}O_9N_3$ , golden-yellow leaflets, which is further transformed into the *semicarbazone*,  $C_{22}H_{26}O_9N_6$ , slender, pale yellow needles, and the crude *monoethyl ester*. The nitroquinone hydrate is reduced by sulphurous acid to the *nitroquinol hydrate*,  $C_{21}H_{25}O_9N_3$ , an amorphous, dark violet powder, m. p. (variable) about 185° (decomp.). The latter is converted by hydrogen chloride in methyl and ethyl alcohols into the *methyl* and *ethyl* esters, amorphous, violet substances. The *triacetyl* derivative of the nitroquinol has m. p. 175–180° (decomp.). The relationships of the quinone and quinol compounds are illustrated by the scheme :

H. W.

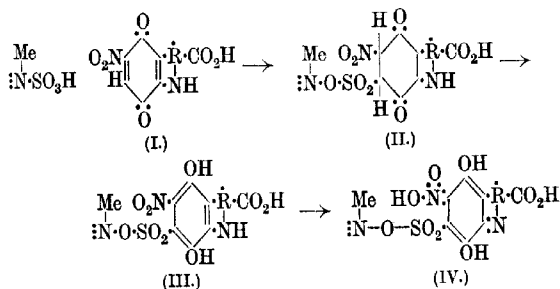

**Strychnos Alkaloids. XXXVI. The Preparation of Methoxy- and Ethoxy-dihydrostrychninolones and of Strychninolone-c; Oxidation of the Latter.** HERMANN LEUCHS and RUDOLF NITSCHKE (*Ber.*, 1922, 55, [B], 3738–3745; cf. A., 1921, i, 883; Leuchs, Grüss, and Heering, preceding abstract).—Strychninolone-*a* is converted by methyl-alcoholic potassium hydroxide solution initially into the *b*-form, and finally into an inseparable mixture of *methoxydihydrostrychninolone* and *strychninolone-c*. The former has been isolated only as a resin which is converted by sodium acetate and acetic anhydride into a crystalline *acetate*,  $C_{22}H_{24}O_9N_2$ , colourless, quadratic crystals, m. p. 237–239° after softening at 230°,  $[\alpha]_D^{20}$  –109° when dissolved in glacial acetic acid. The course of the change is followed more readily when the methyl- is replaced by ethyl-alcoholic potassium hydroxide solution, since in this instance *ethoxydihydrostrychninolone*, needles, m. p. about 100°,  $[\alpha]_D^{20}$  –51.9° in glacial acetic acid solution, m. p. (+MeOH), 65–70°, can be isolated directly.

Strychninolone-*c* is transformed by acetic anhydride and sodium acetate into *acetylstrychninolone-c*,  $C_{21}H_{20}O_4N_2$ , domatic prisms, m. p. 256–257°,  $[\alpha]_D^{20}$  –229.6° in glacial acetic acid solution. The latter substance is oxidised in acetone solution by powdered potassium permanganate to an *acid*,  $C_{21}H_{20}O_6N_2 \cdot H_2O$ , colourless prisms, m. p. 280–282° (decomp.) after softening at 260°, in which, however, the water of crystallisation appears to be retained with

unusual tenacity. The acid is converted by hydrochloric acid into acetic and oxalic acids and a non-crystalline, unstable hydrochloride. The behaviour of acetylstrychninone-*c* is closely analogous to that of cryptobrucinolone; each probably contains the oxidisable group,  $\text{CH} \begin{smallmatrix} \text{R}=\text{N} \\ \text{CH}\cdot\text{CO} \end{smallmatrix}$ , which is transformed by oxygen into  $\text{CO}_2\text{H}\cdot\text{R}\cdot\text{N}\cdot\text{CO}\cdot\text{CO}_2\text{H}$ .

H. W.

**Strychnos Alkaloids. XXXVII. The Degradation of Methylcacotheline and its Violet Colour-reaction with Sodium Sulphite.** HERMANN LEUCHS, BERNHARD WINKLER, and W. ROBERT LEUCHS (*Ber.*, 1922, 55, [B], 3936—3950).—Among the violet products which are formed from cacotheline and analogous substances of the brucine series, methylcacotheline methosulphite (A., 1919, i, 35) occupies a peculiar position, since it becomes isomerised when heated, with the production of a violet isomeride which is therefore not formed in the usual manner by the addition of two atoms of hydrogen. The isomerism cannot be regarded as definitely proved by analytical methods, since the presence of two additional atoms of hydrogen in the molecule does not greatly affect the composition, but it is now placed beyond doubt by the observations that the substance is produced in 50% yield by the action of one molecular proportion of sodium sulphite on two molecular proportions of methylcacotheline, that sulphuric acid is not produced thereby, and that the remainder of the methylcacotheline passes into the yellow methylbetaine (cf. A., 1920, i, 179), which is convertible by further treatment with sodium hydrogen sulphite into the violet methosulphite. The reactions which take place in the production of the violet methosulphite are indicated by the scheme:

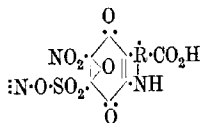

The ammonium sulphite becomes added to the quinone nucleus with the formation of a phenylsulphite ester group or a sulphonic acid, whereupon the quinone becomes isomerised to quinol without addition of extraneous hydrogen; the nitro-group subsequently passes into the *isonitro*-form with production of a new quinonoid arrangement and development of the dark colour.

The so-called violet "methosulphite" (formula IV) is converted

by drastic treatment with hydrogen chloride and ethyl alcohol into a *monoethyl ester*,  $C_{22}H_{29}O_{10}N_3S$ , dark violet prisms, and by acetic anhydride and anhydrous sodium acetate at  $100^\circ$  into an *anhydride*,  $C_{22}H_{23}O_9N_3S$  (the *ammonium salt*, orange-coloured needles, and the *diacetyl derivative*,  $C_{28}H_{47}O_{11}N_3S$ , pale yellow leaflets, are described). The sulphite,  $C_{22}H_{25}O_{10}N_3S$ , is transformed by methyl sulphate and alkali hydroxide into a *monomethyl derivative*,  $C_{23}H_{27}O_{10}N_3S$ , a blackish-violet, crystalline powder. Reduction of the violet sulphite or of the corresponding quinone with tin and hydrochloric acid has been shown previously (A., 1919, i, 36) to yield a colourless compound,  $C_{22}H_{25}O_7N_3S$ , the formation of which is now interpreted as due to the reaction of the  $:NH$  and  $\cdot CO_2H$  groups to form  $\cdot N\cdot CO\cdot$ . The main product formed by the action of sodium sulphite and sulphurous acid on the quinol from methylcatheline (A., 1920, i, 178) is the compound  $C_{22}H_{27}O_{11}N_3S_2$ , almost colourless, four-sided plates or prisms, in which the  $\cdot N\cdot CO\cdot$  group of the substance described above has become transformed into  $\cdot NH\cdot CO_2H$ , and the  $NH_2$  group into  $\cdot NH\cdot SO_3H$ . A second product,  $C_{22}H_{24}O_8N_3S$ , needles, appears to be derived from  $C_{22}H_{25}O_7N_3S$  by the conversion of the amino- into the hydroxy-group.

The violet methosulphite is converted by passing oxygen through its ammoniacal solution into a substance (cf. A., 1919, i, 35) to which the composition  $C_{22}H_{29}O_{11}N_3S$  (instead of  $C_{21}H_{23}O_{11}N_3S$ ) is now assigned, and for which the annexed structure is suggested. The substance is re-transformed into the violet methosulphite by drastic reduction with sulphurous acid, whereas, when treated with tin and hydrochloric acid, it gives the amine hydrochloride,  $C_{22}H_{25}O_7N_3S\cdot HCl\cdot 4H_2O$  (the

corresponding *sulphate*, *nitrate*, and *hydrobromide* are described), and small quantities of a compound,  $C_{22}H_{29}O_9N_3S\cdot HCl\cdot 2H_2O$ , thin prisms. Esterification of the compound  $C_{22}H_{29}O_{11}N_3S$  by methyl or ethyl alcohol in the presence of hydrogen chloride yields products which contain halogen, whereas when sulphuric acid is used the corresponding *dimethyl* compound,  $C_{24}H_{29}O_{12}N_3S$ , pale green prisms, and *diethyl derivative*,  $C_{26}H_{33}O_{12}N_3S$ , rectangular prisms, which is hydrolysed by potassium carbonate solution to the *monoethyl* compound,  $C_{24}H_{29}O_{12}N_3S$ , almost colourless, short prisms, are obtained. The dialkyl derivatives are produced by the esterification of the carboxy-group and the addition of alcohol consequent on the rupture of the ethylene oxide bridge with production of the group  $\cdot C(OH)\cdot C(OAlk)\cdot$ .

The oxidation of the violet nitroquinol by air does not therefore lead to any considerable degradation of the molecule. A more drastic change is effected when the original material, methylcatheline, is treated with a solution of bromine in hydrobromic acid. Two products are thereby obtained, the first of which, produced in 30% yield, has the formula  $C_{20}H_{25}O_6N_2Br$ , and crystallises in colourless, rectangular prisms or leaflets,  $[\alpha]_D^{25} - 6.75^\circ$  in

aqueous solution (corresponding *nitrate*, colourless needles or prisms,  $[\alpha]_D^{20} -7.4^\circ$  when dissolved in water); it appears to be analogous to the salt,  $C_{19}H_{23}O_6N_2 \cdot HBr$ , prepared by Hanssen (A., 1887, 505; cf. Leuchs, Millbrand, and Leuchs, A., 1922, i, 1052) by the action of bromine water on cacotheline. The second compound is obtained initially in unstable union with sulphurous acid, after the removal of which it has the composition  $C_{18}H_{23}O_6N_2Br_2$ ,  $[\alpha]_D^{20} -4.3^\circ$  in aqueous solution; it appears to be a *N*-methyl derivative of a dibrominated bromide.

The methyl ester of the oxime of cacotheline methochloride is converted by methyl alcoholic ammonia at  $100^\circ$  into the *methyl* ester of the *nitrosophenolmethylbetaine*,  $C_{22}H_{26}O_7N_4$ , apple-green prisms. H. W.

**Nitropyrroles.** ANGELO ANGELI (*Atti R. Accad. Lincei*, 1922, [v], 34, ii, 3—5).—Fischer and Zerweck (A., 1922, i, 758) state inaccurately that the nitration of alkylpyrroles may be effected smoothly by means of nitric acid (cf. Angeli, A., 1911, i, 397). The compounds investigated by these authors are not alkylpyrroles, but esters of carboxylic acids derived from keto-, formyl-, etc., derivatives of pyrrole, and the action on them of nitric acid consists, not in true nitration, but in replacement of acetyl, aldehyde-, methyl, etc., groups by nitro-groups. T. H. P.

**Melanins from Pyrrole Derivatives.** PIETRO SACCARDI (*Biochem. Z.*, 1922, 132, 443—456).—A general review of the relations of melanin pigment to the pyrrole group. W. O. K.

**The Tetrachlorodipyridinoiridates.** MARCEL DELÉPINE (*Compt. rend.*, 1922, 175, 1075—1077; cf. A., 1922, i, 859).—Details of the preparation of the red and orange isomerides of potassium tetrachlorodipyridinoiridate by the action of pyridine on potassium iridichloride or potassium aquapentachloroiridate are given, together with an account of certain of their properties. The introduction of pyridine into the complex diminishes the number of acid functions and at the same time renders the substance more stable. H. J. E.

**The Reaction between Acetylene and Aniline at High Temperatures.** RIKO MAJIMA, TADASHI UNNO, and KASHICHI IINO (*Ber.*, 1922, 55, [B], 3854—3859).—The production of small quantities of indole by subjecting a mixture of acetylene and aniline to a red heat has been observed previously in the presence of aluminium oxide as catalyst. Experiments in which the latter was replaced by the oxides of silicon, iron, chromium, thorium, nickel, cobalt, manganese, molybdenum, tungsten, vanadium, or titanium, or by metallic nickel, iron, cobalt, platinum, palladium, samium, or copper, did not lead to satisfactory results; nickel was the most powerful catalyst, but speedily loses its activity. Better results are obtained by leading a mixture of aniline vapour, acetylene, and carbon dioxide through a tube heated at  $600-700^\circ$ , thereby, under the most favourable conditions, the yield of indole

amounts to 34% of the changed aniline. Benzene, carbazole, and  $\beta$ -naphthylamine are produced in considerably smaller quantity, and still smaller amounts of pyrrole, naphthalene, and quinoline are formed. Glass and porcelain tubes are unsatisfactory on account of frequent breakage, but excellent service is rendered by wide iron tubes which have been subjected to previous protracted heating at 600–650° in a current of acetylene, whereby the inner surface becomes coated with a thin, black, compact layer possibly composed of carbon.

The formation of indole and  $\beta$ -naphthylamine is probably due to the intermediate production of vinylaniline, thus:  $\text{NH}_2\text{Ph} + \text{CH}:\text{CH} \rightarrow \text{NHPh}\cdot\text{CH}:\text{CH}_2 \xrightarrow{-\text{H}_2} \text{C}_6\text{H}_4\langle\begin{smallmatrix} \text{CH} \\ \text{NH} \end{smallmatrix}\rangle\text{CH}$  and  $\text{NHPh}\cdot\text{CH}:\text{CH}_2 \rightarrow \text{CH}_2:\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2 \xrightarrow{+\text{C}_2\text{H}_2} \text{C}_{10}\text{H}_7\cdot\text{NH}_2$ . Carbazole is probably attributable to intermediate diphenylamine. It is uncertain whether carbon dioxide acts merely as a diluent or takes part in the change in accordance with the equation

other gases, such as ammonia, hydrogen, nitrogen, or water vapour, give less satisfactory results. H. W.

**Catalytic Hydrogenation under Pressure in the Presence of Nickel Salts. IV. Quinoline Bases.** JULIUS VON BRAUN, ADOLF PETZOLD, and JON SEEMANN (*Ber.*, 1922, 55, [B], 3779–3792).—Under the conditions used by the authors, quinoline is readily and quantitatively hydrogenated at 210–215° into 1:2:3:4-tetrahydroquinoline, which can thus be prepared more readily than by the older methods. At 250°, a portion of the tetrahydro-base is reduced further to decahydroquinoline, and another portion is reduced to tertiary bases of pyridine character which have not been fully examined. Quinoline derivatives which contain a substituent in the benzenoid nucleus or in position 1 behave in the same manner as the parent bases, whereas those which have a substituent in position 3 are also hydrogenated in the benzenoid nucleus to an extent which depends on the particular substituent present.

The reductions are effected with the pure bases or with solutions of them in tetra- or deca-hydronaphthalene. The results are similar in every case, and the rate of absorption of the gas is not appreciably influenced by the diluent.

6-Methylquinoline is converted at 120° into 6-methyl-1:2:3:4-tetrahydroquinoline, b. p. 131–133°/9 mm., m. p. 37–38°, the yield being 90% of that theoretically possible. 6-Chloro-1:2:3:4-tetrahydroquinoline, long, colourless needles, m. p. 43°, b. p. 155°/18 mm., is prepared at 160°; the corresponding hydrochloride, m. p. 190°, picrate, yellow needles, m. p. 150°, and nitroso-derivative, yellow, lustrous prisms, m. p. 67°, are described.

[With A. SCHULTHEISS.]—6:7-Ethylenedioxyquinoline (Sonn and Benirschke, A., 1921, i, 805) is very readily hydrogenated at 180–190° to 6:7-ethylenedioxy-1:2:3:4-tetrahydroquinoline,

b. p.  $193^{\circ}/11$  mm., m. p.  $101^{\circ}$  (*picrate*, m. p.  $168^{\circ}$ ; hydrochloride, m. p.  $199^{\circ}$  (Sonn and Benirschke give m. p.  $201^{\circ}$ ); nitroso-derivative, m. p.  $110^{\circ}$ ).

2-Phenyl-1:2:3:4-tetrahydroquinoline, b. p.  $196-197^{\circ}/12$  mm., obtained from 2-phenylquinoline at  $150^{\circ}$ .

3-Ethylquinoline, an almost colourless liquid with an odour of quinoline, is prepared in 80% yield by the action of *n*-butyraldehyde on *o*-aminobenzaldehyde at  $120-130^{\circ}$  (cf. Wislicenus and Elvert, A., 1909, i, 420); it has b. p.  $135-138^{\circ}/12$  mm.,  $d_4^{20}$  1.0508,  $n_D^{20}$  1.6030 (hydrochloride, m. p.  $173^{\circ}$ ; *picrate*, m. p.  $197^{\circ}$ ; *methiodide*, m. p.  $191^{\circ}$ ). The base is readily hydrogenated at  $180-190^{\circ}$ , yielding thereby a mixture of 3-ethyl-5:6:7:8-tetrahydroquinoline and 3-ethyl-1:2:3:4-tetrahydroquinoline, which are separated from one another with the aid of benzoyl chloride. The former is a colourless liquid, b. p.  $125-128^{\circ}/12$  mm.,  $d_4^{20}$  0.99218,  $n_D^{20}$  1.5311; it gives a *methiodide*, m. p.  $120^{\circ}$ , and a *picrate*, yellow crystals, m. p.  $158^{\circ}$ . The latter has b. p.  $140^{\circ}/12$  mm.,  $d_4^{20}$  1.0041,  $n_D^{20}$  1.5625 (hydrochloride, m. p.  $210^{\circ}$ ; *picrate*, m. p.  $142^{\circ}$ ; *methiodide*,  $C_{18}H_{20}NI$ , m. p.  $205^{\circ}$ ; the benzoyl and nitroso-derivatives are non-crystalline).

3-*n*-Amylquinoline, prepared in almost quantitative yield from *o*-aminobenzaldehyde and heptaldehyde at  $180^{\circ}$ , is a colourless liquid, b. p.  $179^{\circ}/16$  mm.,  $d_4^{20}$  1.0048,  $n_D^{20}$  1.5715 (hydrochloride, m. p.  $174^{\circ}$ ; *picrate*, m. p.  $153^{\circ}$ ; *methiodide*, m. p.  $69^{\circ}$ ). It is hydrogenated at  $180-190^{\circ}$  with the formation of approximately equal amounts of 3-*n*-amyl-1:2:3:4-tetrahydroquinoline, a colourless liquid, b. p.  $159-164^{\circ}/12$  mm.,  $d_4^{20}$  0.96625,  $n_D^{20}$  1.5339 (hydrochloride, needles, m. p.  $124^{\circ}$ , *methiodide*,  $C_{16}H_{26}NI$ , m. p.  $145^{\circ}$ ; the *picrate*, benzoyl compound, acetyl derivative, and nitroso-compound are non-crystalline) and 3-*n*-amyl-5:6:7:8-tetrahydroquinoline, a colourless, nearly odourless liquid, b. p.  $167^{\circ}/12$  mm.,  $d_4^{20}$  0.96028,  $n_D^{20}$  1.5188. The latter substance gives a *picrate*, long needles, m. p.  $135^{\circ}$ , and a *methiodide*, m. p.  $105^{\circ}$ , whereas the chloride and chloroplatinate are non-crystalline; it does not react with acetic anhydride or nitrous acid. The base is oxidised by potassium permanganate to oxalic and pyridine-2:3:5-tricarboxylic acids.

3-Phenylquinoline is hydrogenated with remarkable ease at  $160^{\circ}$  to a mixture of 3-phenyl-1:2:3:4-tetrahydroquinoline and 3-phenyl-5:6:7:8-tetrahydroquinoline, from which the former is very readily separated by taking advantage of its sparing solubility in alcohol, with which the latter is readily miscible. 3-Phenyl-1:2:3:4-tetrahydroquinoline is a colourless, crystalline substance, m. p.  $83^{\circ}$  (hydrochloride, matted needles, m. p.  $229^{\circ}$ ; *picrate*, m. p.  $181^{\circ}$ ; *picrolonate*, a yellow powder, m. p.  $205^{\circ}$ ; acetyl derivative, feathery crystals, m. p.  $78^{\circ}$ ; nitroso-compound, m. p.  $147^{\circ}$ ). 3-Phenyl-5:6:7:8-tetrahydroquinoline is a colourless liquid, b. p.  $211-212^{\circ}/18$  mm. (hydrochloride, m. p.  $235^{\circ}$  after darkening at  $225-230^{\circ}$ ; *picrolonate*, a yellow powder, m. p.  $201^{\circ}$ ; *methiodide*,  $C_{18}H_{20}NI$ , m. p.  $240-243^{\circ}$ ; the base does not react with nitrous acid or acetic anhydride). 3-Phenyl-5:6:7:8-tetrahydro-

quinoline is reduced by sodium and ethyl alcohol to 3-phenyl-decahydroquinoline, colourless crystals, m. p. 98° after softening at 95° (nitroso-derivative, m. p. 110°; *picrate*, m. p. 210—212°; the acetyl compound could not be caused to crystallise). H. W.

**The Relative Stability of Cyclic Bases. VII. Substituted Tetrahydroquinoline Rings.** JULIUS VON BRAUN, JON SEE-MANN, and ADAM SCHULTHEISS (*Ber.*, 1922, 55, [B], 3803—3817).—In previous communications (von Braun and Neumann, A., 1917, i, 282; von Braun, Heider, and Neumann, A., 1917, i, 167), it has been pointed out that whereas the stability of the tetrahydroquinoline ring towards scission during reduction by sodium amalgam is little affected by the introduction of the methyl group in position 2, that of the dihydroindole ring is modified profoundly by 2 or 3 methylation. The presence of a methyl group in position 3 or 4 in the tetrahydroquinoline ring is now shown not to exert a marked effect on the course of the change. On the other hand, the presence of a phenyl group in position 2 causes the almost quantitative rupture of the non-aromatic ring linking, whereas when the group is in position 3 the three possible types of change are realised.

1:3-Dimethyl-1:2:3:4-tetrahydroquinoline,  $C_6H_4 \begin{smallmatrix} \text{CH}_2-\text{CHMe} \\ \text{NMe}-\text{CH}_2 \end{smallmatrix}$ ,

an almost colourless liquid, b. p. 130—132°/17 mm., is obtained by the reduction of 3-methylquinoline methiodide by tin and hydrochloric acid; the very hygroscopic *hydrochloride*, m. p. about 110°, *picrate*, m. p. 131°, and *methiodide*, m. p. 204°, are described. The corresponding quaternary *chloride* is converted by sodium amalgam into a mixture of 1:3-dimethyl-1:2:3:4-tetrahydroquinoline and  $\gamma$ -phenyl-3-methylpropyldimethylamine,

from which the former is removed by treatment with formaldehyde in hydrochloric acid solution. The latter base is a colourless liquid, b. p. 100—105°/7 mm., 221°/atmospheric pressure (*hydrochloride*, m. p. 90°; *picrate*, m. p. 87°; *methiodide*, m. p. 140°).

1:4-Dimethyl-1:2:3:4-tetrahydroquinoline *methiodide* is converted into the corresponding *chloride*, which is transformed by sodium amalgam into 1:4-dimethyl-1:2:3:4-tetrahydroquinoline and  $\gamma$ -phenylbutyldimethylamine,  $CHMePh-CH_2-CH_2-NMe_2$ , a liquid, b. p. 112—115°/7 mm. (*hydrochloride*, m. p. 100°; *picrate*, m. p. 98°; *methiodide*, m. p. 125°), which constitutes 60% of the mixture of bases.

2-Phenyl-1:2:3:4-tetrahydroquinoline is converted by methyl iodide and aqueous alkali mainly into 2-phenyl-1-methyl-1:2:3:4-tetrahydroquinoline, colourless crystals, m. p. 101°, b. p. 188—192°/14 mm.; the corresponding *hydrochloride*, m. p. 157°, *chloroplatinate*, m. p. 172°, *nitroso*-compound, a microscopic, green powder, m. p. 75°, and *diphenylmethane* derivative,  $C_{17}H_{19}N$ , m. p. 60° after slight previous softening, are described. The base unites with difficulty with methyl iodide to give the quaternary *iodide*,  $C_{17}H_{19}NI$ , m. p. 185°. The quaternary *chloride* (*chloro-*

platinate, orange-coloured crystals, m. p. 203°) is almost quantitatively converted by sodium amalgam into *o*- $\gamma$ -phenylpropyldimethylaniline,  $\text{NMe}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}_2\text{Ph}$ , b. p. 175–178°/10 mm. The *picrate*, golden-yellow needles, m. p. 110°, the non-crystalline *hydrochloride*, and the *chloroplatinate*, a yellowish-brown powder, n. p. 170°, are described. The base does not unite readily with methyl iodide, thus proving that the dimethylamino-group is attached to the benzenoid nucleus and is sterically hindered, and that the compound is not the isomeric substance,

2-Phenyl-1-methyl-1:2:3:4-tetrahydroquinoline suffers fission in accordance with the scheme  $\text{C}_6\text{H}_4\left\langle\begin{smallmatrix}\text{CH}_2-\text{CH}_2 \\ \text{NMe}\cdot\text{CHPh}\end{smallmatrix}\right\rangle + \text{BrCN} \rightarrow$

$\text{CN}\cdot\text{NMe}\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CHPhBr}$  to the extent of at least 50% when treated with cyanogen bromide in a gently boiling water-bath. Since cyanoamides cannot be distilled without decomposition and seldom crystallise, the product of the action is treated directly with an excess of piperidine, whereby it is converted into a portion insoluble in acid, b. p. 218°/vacuum, and a bromine-free, amorphous base which readily unites with methyl iodide, giving the substance  $\text{C}_{22}\text{H}_{20}\text{N}_3\text{I}$ , a pale-brown, microcrystalline powder which loses methyl iodide without definitely melting above 60°.

The *hydroxide*,  $\text{C}_6\text{H}_4\left\langle\begin{smallmatrix}\text{CH}_2-\text{CH}_2 \\ \text{NMe}_2(\text{OH})\end{smallmatrix}\right\rangle\text{CHPh}$ , is mainly decomposed with loss of methyl alcohol when distilled under diminished pressure, giving 2-phenyl-1-methyl-1:2:3:4-tetrahydroquinoline.

In striking contrast to the 2-phenyl derivative, 3-phenyl-1:2:3:4-tetrahydroquinoline is readily converted by methyl iodide into the quaternary *iodide*,  $\text{C}_{17}\text{H}_{20}\text{NI}$ , m. p. 172°, which loses methyl iodide when distilled under diminished pressure and gives 3-phenyl-1-methyl-1:2:3:4-tetrahydroquinoline, m. p. 42°, b. p. 195–202°/12 mm. The corresponding *picrate*, m. p. 178°, the non-crystalline *hydrochloride*, and *chloroplatinate*, m. p. 192°, the *nitroso*-compound, m. p. about 105°, and the diphenylmethane derivative,  $\text{C}_{30}\text{H}_{24}\text{N}_2$ , m. p. 92°, are described. The quaternary *chloride* (*chloroplatinate*, m. p. 204°) is converted by sodium amalgam into a mixture of 3-phenyl-1-methyl-1:2:3:4-tetrahydroquinoline (47%),  $\beta$ -*phenylpropyldimethylamine*,

(45%), and *o*- $\beta$ -phenylpropyldimethylaniline,

(3%). The two bases last mentioned are separated by taking advantage of the inability of the *o*-dimethylaniline derivative to unite with methyl iodide in ethereal solution. The quantity of  $\beta$ -phenylpropyldimethylaniline available was insufficient to permit its isolation in a homogeneous condition, and it is characterised by its *picrate*, m. p. 166–167°, non-crystalline *hydrochloride*, and *chloroplatinate*, m. p. 181°.  $\beta$ -*Diphenylpropyldimethylamine* *methide* is exceedingly hygroscopic; it is converted into the corresponding *chloride* (*chloroaurate*, yellow needles, m. p. 164°; *chloroplatinate*, a microcrystalline powder, m. p. 236°). The constitution

of the iodide is established by the observation that the corresponding *hydroxide* is decomposed when distilled under diminished pressure into  $\alpha$ -benzylstyrene,  $\text{CH}_2\text{Ph}\cdot\text{CPh}\cdot\text{CH}_2$ , a liquid, b. p.  $140-148^\circ/\text{vacuum}$ ,  $d_4^{20} 1.0143$ ,  $n_D^{20} 1.5903$  (corresponding *dibromide*, colorless crystals, m. p.  $98^\circ$ ). 3-Phenyl-1-methyl-1:2:3:4-tetrahydroquinoline is converted to a slight extent by cyanogen bromide into the corresponding *methobromide* (identified by its conversion into the chloroplatinate, m. p.  $203^\circ$ ) but mainly into 1-cyano-3-phenyl-1:2:3:4-tetrahydroquinoline, m. p.  $78^\circ$ ; fission of the ring, as in the case of the 2-phenyl compound, is not observed.

6:7-Ethylenedioxyquinoline methiodide, m. p. 270°, is reduced by tin and hydrochloric acid to 6:7-ethylenedioxy-1-methyl-1:2:3:4-tetrahydroquinoline, colourless leaflets, m. p. 53°, b. p. 165–170°/8 mm.; the hydrochloride, m. p. 203°, picrate, m. p. 170°, and the methiodide, m. p. 220°, are described. The latter compound is prepared more advantageously by exhaustive methylation of 6:7-ethylenedioxy-1:2:3:4-tetrahydroquinoline. It is converted into the corresponding chloride which is transformed by sodium amalgam into a mixture of 6:7-ethylenedioxy-1-methyl-1:2:3:4-tetrahydroquinoline (40%) and  $\gamma$ -3:4-ethylenedioxy-phenylpropyldimethylamine,  $C_2H_5O_2C_3H_7[CH_2]_3NMe_2$ , b. p. 162–164°/7 mm., which are separated from one another by careful fractional distillation; the methiodide, m. p. 165°, picrate, m. p. 167°, and hydrochloride, m. p. 169°, of the latter base are described. H. W.

**The Mechanism of Syntheses of isoQuinoline from Benzylamine Derivatives.** PAUL STAUB (*Helv. Chim. Acta*, 1922, 5, 889-894).—Many attempts to synthesise isoquinoline derivatives by ring closure in appropriate benzylamine derivatives are recorded in the literature, but few were successful. In an attempt to determine the conditions requisite for success, the following new compounds were prepared for ring closure experiments.

$\alpha$ -Benzylideneaminoisopropyl alcohol,  $\text{CHPh:N-CH}_2\text{-CHMe-OH}$ , was obtained by reducing nitroisopropyl alcohol,

and condensing the product with benzaldehyde; it crystallises in needles, m. p. 76–76.5°.

Benzylaminoisopropyl alcohol,  $\text{CH}_2\text{Ph}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CHMe}\cdot\text{OH}$ , was obtained by the action of benzyl chloride on aminoisopropyl alcohol; b. p.  $142^\circ/11$  mm.

*Benzenesulphonbenzyl-β-hydroxyethylamide*,

$$\text{CH}_2\text{Ph}\cdot\text{N}(\text{SO}_2\text{Ph})\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{OH},$$

was prepared by heating benzenesulphonbenzylamide with ethylene oxide at 170°; it formed a viscous liquid crystallising slowly, and was not purified.

*Benzenesulphonbenzyl-β-bromoethylamide,*

$$\text{CH}_2\text{Ph}\cdot\text{N}(\text{SO}_2\text{Ph})\cdot\text{CH}_2\cdot\text{CH}_2\text{Br},$$

was formed by the action of ethylene bromide on sodium benzene-sulphonbenzylamide in ether; m. p. 82.5–83°.

*Benzenesulphonbenzylphenacylamide,*

was prepared by the action of bromoacetophenone on sodium benzenesulphonbenzylamide in ether. The product was not crystallised.

*Acetobenzylphenacylamide*,  $\text{CH}_2\text{Ph}\cdot\text{N}(\text{Ac})\cdot\text{CH}_2\cdot\text{COPh}$ , was obtained as a syrup from the action of bromoacetophenone on sodium benzylacetamide.

In no case could any *isoquinoline* derivative be obtained by the action of any of the usual ring-closing agents on any of the above six compounds.

It is concluded that a benzene derivative containing the chain  $\text{Ph}\cdot\text{C}\cdot\text{N}\cdot\text{C}\cdot\text{C}-$  must, if it is to be convertible into an *isoquinoline* base, conform to two rules. In the lateral chain it must have (1) a system of conjugated double bonds, actual or potential; (2) a hydroxyl or alkoxyl group in  $\beta$ -position to the nitrogen atom. The compound  $\text{CHPh}\cdot\text{N}\cdot\text{CH}_2\cdot\text{CH}(\text{OEt})_2$  conforms to condition (1) by loss of alcohol, and readily forms *isoquinoline*. Benzylaminoacetaldehyde,  $\text{CH}_2\text{Ph}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CHO}$ , which is converted by fuming sulphuric acid into *isoquinoline*, may be supposed to undergo oxidation and by passing into the tautomeric form,

satisfies the conditions.

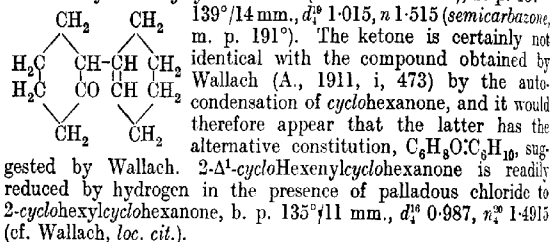

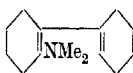

E. H. R.

**Catalytic Hydrogenation under Pressure in the Presence of Nickel Salts. V. The Carbazole Complex.** JULIUS VON BRAUN and HEINRICH RITTER (*Ber.*, 1922, 55, [B], 3792—3803; cf. Padoa and Chiaves, A., 1908, i, 772).—The process used by the authors does not cause the hydrogenation of pyrazole even at 260° and under a pressure of 30 atmospheres, in spite of the use of a material which has been exhaustively purified in several different manners. Nevertheless, the authors are inclined to the view that pure pyrazole is not unusually resistant to hydrogenation, and that the failure of their experiments is due to some unknown catalytic impurity. The *N*-alkylcarbazoles are readily hydrogenated with initial addition of four hydrogen atoms to one benzene nucleus. Subsequently, the second benzene nucleus is attacked with addition of a further four atoms of hydrogen.

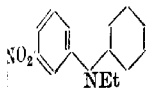

9-Methylcarbazole readily absorbs about seven atomic proportions of hydrogen at 210—215° and 25 atmospheres pressure. About 40% of the initial material remains unchanged whilst a portion is perhydrogenated with production of ammonia. The liquid product of the reaction is a mixture of the octahydro- and tetrahydro-derivatives with 9-methylcarbazole, from which the first-named is readily separated by treatment with hydrochloric acid (20%), in which it alone dissolves. The remaining bases cannot be separated from one another by distillation or crystallisation; the presence of the tetrahydro-compound is established by the formation of the strongly basic hexahydro-derivative when the mixture of bases is treated with tin and hydrochloric acid.

9-Methyloctahydrocarbazole,  $\text{MeN} \begin{smallmatrix} \text{C}_6\text{H}_8 \\ \text{C}_6\text{H}_8 \end{smallmatrix}$ , lustrous leaflets, m. p. 94°, b. p. 176–178°/16 mm., is somewhat unstable towards air and does not give the pine-shaving or the dimethylaminobenzaldehyde reaction. It does not give a well-defined picrate or methiodide; it is readily oxidised by chromic acid, potassium permanganate, or ferric chloride, but it has not yet been found possible to isolate uniform products of the action. It is conveniently reduced by tin and boiling hydrochloric acid (20%) to 9-methyldecahydrocarbazole,  $\text{MeN} \begin{smallmatrix} \text{C}_8\text{H}_{10} \\ \text{C}_8\text{H}_{10} \end{smallmatrix}$ , a colourless, mobile liquid, b. p.

138–139°/12 mm., which is stable towards air; the non-crystalline hydrochloride, hydrobromide, m. p. 202–204°, picrate, m. p. 162°, and methiodide, m. p. 189°, are described. The presence of the double bond in the base is betrayed only by its instability towards permanganate; it yields only the hydrobromide when treated with fuming hydrobromic acid and does not unite with bromine or hydrogen even under widely varied conditions. The methiodide is transformed by successive treatment with silver oxide and distillation into 2-dimethylamino- $\Delta^{1:1'}$ -dicyclohexenyl (annexed formula), an almost colourless liquid, b. p. 148°/15 mm., which is conveniently characterised as the picrate, m. p. 157°. The new base is somewhat unstable and is readily converted by sulphuric acid (10%) into 2- $\Delta^1$ -cyclohexenylcyclohexanone (annexed formula), b. p. 131–139°/14 mm.,  $d_4^{20}$  1.015,  $n_D^{20}$  1.515 (semicarbazone, m. p. 191°). The ketone is certainly not identical with the compound obtained by Wallach (A., 1911, i, 473) by the autocondensation of cyclohexanone, and it would therefore appear that the latter has the alternative constitution,  $\text{C}_6\text{H}_8\text{O} \cdot \text{C}_6\text{H}_{10}$ , suggested by Wallach. 2- $\Delta^1$ -cyclohexenylcyclohexanone is readily reduced by hydrogen in the presence of palladium chloride to 2-cyclohexylcyclohexanone, b. p. 135°/11 mm.,  $d_4^{20}$  0.987,  $n_D^{20}$  1.4915 (cf. Wallach, loc. cit.).

The reduction of 9-ethylcarbazole is very similar to that of the methyl compound. 9-Ethylcarbazole, lustrous leaflets, m. p. 43°, b. p. 162–163°/9 mm., is unstable towards air; it does not give a methiodide or a picrate. It is readily reduced to 9-ethyldecahydrocarbazole, a colourless liquid which is stable towards air, b. p. 140–141°/12 mm.; the non-crystalline hydrochloride, the picrate, m. p. 133°, and the methiodide, m. p. 176–177°, are described. 2-Methylethylamino- $\Delta^{1:1'}$ -dicyclohexenyl is a colourless liquid, b. p. 148–150°/12 mm., which gives a non-crystalline picrate and methiodide. It is readily transformed by dilute sulphuric acid into 2- $\Delta^1$ -cyclohexenylcyclohexanone and methyl-ethylamine. 9-Ethylhexahydrocarbazole is a colourless, odourless liquid, b. p. 155–157°/8 mm., 292–293°/749 mm.; it gives a well-defined methiodide, m. p. 174°. The base is transformed by a mixture of nitric and sulphuric acids at 0° into the nitro-com-

compound (annexed formula), golden-yellow needles, m. p.  $142^{\circ}$ , which is reduced by stannous chloride to 7-amino-9-ethylhexahydrocarbazole, an almost colourless, very viscous liquid, b. p.  $224-225^{\circ}/24$  mm., which shows all the colour reactions

characteristic of the simpler meta-diamines of the aromatic series.

It has not been found possible to effect the smooth dehydrogenation of 9-methyl- or 9-ethyl-hexahydrocarbazole; if the substances are passed over lead oxide and pumice the alkyl residues are lost and carbazole is produced.

H. W.

**Benzo-polymethylene Compounds. VIII. Cyclic Analogues of Atophan.** JULIUS VON BRAUN and PAUL WOLFF (*Ber.*, 1922, 55, [B], 3675-3688).—1-Ketotetrahydronaphthalene condenses

readily with isatin to give 5:6-dihydro- $\alpha$ -naphthacridine-7-carboxylic acid (annexed formula), which readily undergoes further change. Constitutionally the new compound (for

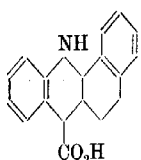

which the name tetraphan is proposed) is allied somewhat closely to 2-phenyl-4-cinchoninic acid (atophan), from which, however, it differs entirely in its physiological action, having a characteristic effect on the spinal marrow somewhat resembling that of strychnine. The physiological properties

of a number of its derivatives have been examined. Substitution in the benzenoid nuclei of the isatin and tetrahydronaphthalene complexes does not affect the qualitative nature of the action. The presence of the basic nitrogen atom and of the carboxyl group appears essential. A new ring produced by the insertion of more than one carbon atom into the atophan complex must be present, which must not be eccentrically united. The group  $-\text{CH}_2\text{CH}_2-$  need not be so fully hydrogenated.

Since tetrahydroatophan shows close physiological resemblance to tetraphan, it is to be expected that the action of the latter would be considerably enhanced by transforming it into its tetrahydro-derivative; the reverse is, however, found to be the case.

5:6-Dihydro- $\alpha$ -naphthacridine-7-carboxylic acid, slender, pale yellow needles, m. p.  $252^{\circ}$  (decomp.), is prepared smoothly by heating a mixture of isatin and 1-ketotetrahydronaphthalene with aqueous-alcoholic potassium hydroxide solution. It reacts incompletely with mineral acids, yielding salts which are hydrolysed by water. The sodium, lead, basic copper, and silver salts are described; the ethyl ester, long, coarse needles, m. p.  $80^{\circ}$ , is prepared from the latter. The acid is decomposed when heated somewhat above its melting point into 5:6-dihydro- $\alpha$ -naphthacridine, b. p.  $237-238^{\circ}/10$  mm., m. p.  $60^{\circ}$ ; the corresponding hydrochloride, long needles, m. p.  $226^{\circ}$ , picrate, m. p.  $206^{\circ}$ , and methiodide, a reddish-yellow, crystalline powder, decomp.  $191^{\circ}$ , are described. The base is readily dehydrogenated by lead oxide at  $300-320^{\circ}$  with production of  $\alpha$ -naphthacridine, m. p.  $108^{\circ}$ . It is oxidised by chromic acid in glacial acetic acid solution to 5:6-diketo- $\alpha$ -naphthacridine, an orange-coloured powder, m. p.  $242^{\circ}$  (a salt with chromic acid is described).

5:6-Dihydro- $\alpha$ -naphthacridine-7-carboxylic acid is converted by bromine and glacial acetic acid at 120–130° into  $\alpha$ -naphthacridine-7-carboxylic acid, a yellow powder, m. p. 261°; the cobalt, copper, mercuric, and silver salts are described. The methyl ester has m. p. 83°. When heated above its melting point, the acid is converted into  $\alpha$ -naphthacridine, m. p. 108°.

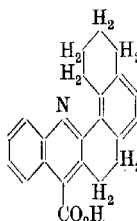

5:6-Dihydro- $\alpha$ -naphthacridine-7-carboxylic acid is reduced by sodium and ethyl or amyl alcohol to 5:6:6a:7:12:12a-hexahydro- $\alpha$ -naphthacridine-7-carboxylic acid (tetrahydrotetrophan) (annexed formula), m. p. 190° (decomp.) after softening at 180°; the corresponding nitroso-compound, m. p. 149°, and acetyl derivative, m. p. 247° after softening at 244°, are described.

5:6-Dihydro-11-methyl- $\alpha$ -naphthacridine-7-carboxylic acid, colourless crystals, m. p. 188° (decomp.), is prepared from 1-ketotetrahydronaphthalene and *o*-methylisatin; its metallic salts closely resemble those of the parent acid. 5:6-Dihydro-11-methyl- $\alpha$ -naphthacridine has m. p. 93–94°, b. p. 248–253°/16 mm.; it yields a picrate, m. p. 141°, and a hydrochloride, long, pale yellow needles, m. p. 173°, but could not be caused to react with methyl iodide. 11-Methyl- $\alpha$ -naphthacridine, m. p. 107°, gives a picrate, m. p. 155°, and a hydrochloride, m. p. 136°, but does not react with methyl iodide.

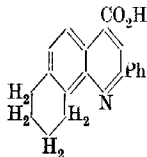

5:6-Dihydro-9-methyl- $\alpha$ -naphthacridine-7-carboxylic acid has m. p. 293° (decomp.); the sodium salt dissolves very sparingly in water.

9-Chloro-5:6-dihydro- $\alpha$ -naphthacridine-7-carboxylic acid, m. p. 283° (decomp.), is converted when heated above its melting point into 9-chloro-5:6-dihydro- $\alpha$ -naphthacridine, m. p. 102°, b. p. 257–262°/14 mm. The hydrochloride of the latter has m. p. 240°. The base loses the chlorine atom when it is treated with lead oxide.

9-Bromo-5:6-dihydro- $\alpha$ -naphthacridine-7-carboxylic acid has m. p. 265°; the silver salt and the methyl ester, yellow leaflets, m. p. 128°, are described. 9-Bromo-5:6-dihydro- $\alpha$ -naphthacridine crystallises in pale yellow needles, m. p. 168° (hydrochloride, m. p. 211–212°).

5:6-Dihydro-1:2-tetramethylene- $\alpha$ -naphthacridine-7-carboxylic acid (annexed formula) is prepared from isatin and  $\alpha$ -keto-octahydrophenanthrene; it has m. p. 210° (decomp.) after darkening at 180°.

2-Acenaphthylquinoline-4-carboxylic acid, prepared from 4-acetylacenaphthene and isatin, has m. p. 234° after previous softening.

Tetramethylenetophan (annexed formula), prepared from *ar*- $\alpha$ -aminotetrahydronaphthylamine, pyruvic acid, and benzaldehyde, forms yellow crystals, m. p. 260° after softening at 255°; its physiological action resembles that of atophan.

H. W.

**The Relationship between Fluorescence and Chemical Constitution in the Case of Derivatives of Benzoxazole. II.**

F. HENRICH [with H. SUNTHEIMER and C. STEINMANN] (*Ber.*, 1922, **55**, [B], 3911—3921).—In a previous communication (*A.*, 1921, i, 886), it has been shown that the development of fluorescence in alkaline solutions of hydroxybenzoxazole derivatives,

$\text{HO}\cdot\text{C}_6\text{H}_3\text{<}\overset{\text{N}}{\text{O}}\text{>C}\cdot\text{R}(\mu)$ , is observed only when R in position  $\mu$  is

an aromatic nucleus directly attached by one of its carbon atoms to the  $\mu$  carbon atom and when the hydroxyl group is in the para-position to the nitrogen atom. This regularity is now shown to be true of certain derivatives of 2:4-dihydroxytoluene.

2:4-Dihydroxytoluene, m. p. 105—107°, is prepared from 2:4-diaminotoluene through the compounds 2-amino-4-acetamidotoluene, 4-acetamido-2-hydroxytoluene, and 4-amino-2-hydroxytoluene; the necessary conditions for each change are described fully in the original. It is converted by amyl nitrite and potassium hydroxide in absolute alcoholic solution into 5-nitroso-2:4-dihydroxytoluene, decomp. 175—180° according to the rate of heating after darkening and softening at 146°; the potassium salt and the benzoyl derivative, m. p. 146—153°, are described.

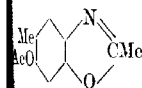

2:4-Dihydroxytoluene is converted by fuming nitric acid in the presence of ether into a mixture of 3-nitro-2:4-dihydroxytoluene, bright red needles, m. p. 111°, and 5-nitro-2:4-dihydroxytoluene, orange-yellow needles, m. p. 118—119°, which can be separated from one another by taking advantage of the volatility of the former with steam, with which the latter does not volatilise.

5-Amino-2:4-dihydroxytoluene hydrochloride, long, colourless needles, is prepared by the reduction of the corresponding nitroso- or nitro-compound with stannous chloride and concentrated hydrochloric acid. The free amine is obtained by the addition of sodium hydroxide to an aqueous solution of the hydrochloride; it dissolves to a dark blue solution in an excess of the reagent, and readily absorbs oxygen, without, however, becoming converted into dyes of the type of litmus. The hydrochloride is transformed by acetic anhydride into 6-acetoxy-2-methyl-5-methylbenzoxazole (anhydrous formula), colourless needles, m. p. 94°, which is converted

by alcoholic potassium hydroxide solution into 6-hydroxy-2:5-dimethylbenzoxazole, colourless crystals, m. p. 221°; the latter substance does not fluoresce in aqueous alkaline solution.

6-Benzoyl-2-phenyl-5-methylbenzoxazole, colourless crystals, m. p. 164—165° after softening at 163°, is prepared from 5-amino-2:4-dihydroxytoluene hydrochloride and benzoyl chloride and is hydrolysed by alcoholic potassium hydroxide solution to 6-hydroxy-2-phenyl-5-methylbenzoxazole, colourless crystals, m. p. 242° after softening at 236°, which has a green fluorescence in aqueous sodium hydroxide solution.

3-Nitro-2:4-dihydroxytoluene is reduced by stannous chloride and concentrated hydrochloric acid to 3-amino-2:4-dihydroxytoluene hydrochloride, colourless needles, which is converted by

successive treatment with benzoyl chloride and alcoholic potassium hydroxide solution into 4-hydroxy-2-phenyl-5-methylbenzoxazole, colourless crystals which do not exhibit fluorescence in alkaline solution. H. W.

**The Relative Stability of Cyclic Bases. VIII. The Phenmorpholine and Homotetrahydroquinoline Rings.** JULIUS VON BRAUN and JON SEEMANN (*Ber.*, 1922, 55, [B], 3818—3825).—It is shown that the stability of the morpholine ring is increased to an unexpected extent by its association with an aromatic ring, so that it is at least as stable towards cyanogen bromide as 1 : 2 : 3 : 4-tetrahydroquinoline and even more stable towards sodium amalgam. Homo-1 : 2 : 3 : 4-tetrahydroquinoline does not suffer fission under the action of cyanogen bromide.

The nine rings (pyrrolidine, piperidine, morpholine, dihydroindole, dihydroisoindole, 1 : 2 : 3 : 4-tetrahydroquinoline, 1 : 2 : 3 : 4-tetrahydroisoquinoline, phenmorpholine, and homo-1 : 2 : 3 : 4-tetrahydroquinoline) exhibit uniformity in their behaviour towards cyanogen bromide, sodium amalgam, and the Hofmann degradation if the dihydroindole and the phenmorpholine systems are not considered. The peculiarity of the latter rings appears to be caused by the presence in them of the group  $-\text{Ar}-\text{N}-\text{CH}_2-\text{CH}_2-$ .

N- $\beta$ -Hydroxyethyl-o-anisidine is conveniently prepared in 75–80% yield by heating o-anisidine with a considerable excess of ethylene chlorohydrin on a water-bath; the *picrate*, m. p. 140°, and the *hydrochloride*, m. p. 134°, are described. The base is converted by successive treatment with concentrated hydrochloric acid at 160–180° and with dilute aqueous alkali into phenmorpholine,  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{O}-\text{CH}_2 \\ | \\ \text{NH}\cdot\text{CH}_2 \end{smallmatrix}$ , b. p. 127–128°/12 mm. The latter is

transformed quantitatively by methyl iodide and sodium hydroxide into 1-methylphenmorpholinium methiodide, which is decomposed when distilled under diminished pressure into 1-methylphenmorpholine, b. p. 124°/12.5 mm. (*picrate*, m. p. 144°).

1-Methylphenmorpholine reacts slowly with cyanogen bromide at the temperature of boiling water, giving unchanged material; 4-methylphenmorpholine *methobromide*, m. p. 213°, and 4-cyano-phenmorpholine,  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{O}-\text{CH}_2 \\ | \\ \text{N}(\text{CN})\cdot\text{CH}_2 \end{smallmatrix}$ , a liquid, b. p. 115–118°/1 mm.;

the latter could not be obtained in a perfectly homogeneous condition, and is characterised by converting it into the guanidine derivative,  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{O}-\text{CH}_2 \\ | \\ \text{N}[\text{C}(\text{NH})\cdot\text{NHPh}]\cdot\text{CH}_2 \end{smallmatrix}$ , small, colourless needles,

m. p. 152°, the non-crystalline *hydrochloride* and *chloroplatinate*, m. p. 144°, of which are described. 4-Methylphenmorpholine methochloride is converted by sodium amalgam almost entirely into 4-methylphenmorpholine which is characterised by its conversion into the *diphenylmethane* derivative,  $\text{C}_{10}\text{H}_{22}\text{O}_2\text{N}_2$ , a very viscous liquid, b. p. about 260°/2 mm. (decomposition occurs before completion of the distillation) (*dimethiodide*, m. p. 157°).

The difficulty of methylating homo-1:2:3:4-tetrahydroquinoline,  $C_6H_4 \begin{smallmatrix} CH_2-CH_2 \\ NH-CH_2 \end{smallmatrix} > CH_2$ , has been indicated previously (von Braun and Bartsch, A., 1913, i, 197); it has now been found possible to isolate the products of the action in a homogeneous form. The quaternary iodide,  $C_{12}H_{18}NI$ , has m. p.  $155^\circ$ . 1-Methylhomo-1:2:3:4-tetrahydroquinoline has b. p.  $108-110^\circ/10$  mm., and gives a picrate, m. p.  $139^\circ$ , a non-crystalline hydrochloride, and a chloroplatinate, m. p.  $186^\circ$ ; it combines very slowly with methyl iodide. It is obtained as the sole basic product when the corresponding quaternary hydroxide is distilled in a vacuum. It is converted by cyanogen bromide into 1-methylhomo-1:2:3:4-tetrahydroquinoline methobromide (identified as the corresponding chloroplatinate, m. p.  $197^\circ$ ) and 1-cyanohomo-1:2:3:4-tetrahydroquinoline,  $C_6H_4 \begin{smallmatrix} [CH_2]_4 \\ N(CN) \end{smallmatrix} >$ , b. p.  $178-182^\circ/13$  mm., which could not be obtained completely free from bromine and is identified by transformation into the guanidine derivative,

**Condensation of Benzidine with Formaldehyde.** HEISA-  
SURO KONDO and SUEZO ISHIDA (*J. Pharm. Soc. Japan*, 1922, 79—985; cf. H. Schiff, A., 1892, 1223).—By adding 30 c.c. of 35% formaldehyde solution to benzidine (10 g.) dissolved in absolute alcohol (200 c.c.), a greyish-white, light, amorphous condensation product, dimethanolbenzidine,  $C_{12}H_8(NH-CH_2OH)_2$ , is precipitated; it has m. p.  $271-272^\circ$  after sintering at  $260^\circ$ , and is sparingly soluble in alcohol or water, but readily soluble in hydrochloric acid. It is not identical with dimethylenebenzidine, m. p.  $140-141^\circ$ , obtained by Schiff by the same method. When dissolved in dilute hydrochloric acid, the odour of formaldehyde is perceptible and from the solution methanolbenzidine hydrochloride,

colourless needles, of high melting point, was isolated by adding concentrated hydrochloric acid. When kept for a long time the solution in hydrochloric acid gave a reddish-violet product identical with the compound,  $C_{15}H_{12}N_2$ , obtained by Schiff. K. K.

**The Behaviour of certain Dibenzamidoethylene Derivatives Prepared from Iminazoles towards Acid Anhydrides. A.**

WINDAUS and W. LANGENBECK (*Ber.*, 1922, 55, [B], 3706—3709; cf. Windaus, Dörries, and Jensen, A., 1922, i, 61).—Dibenzamidoethylene derivatives are converted by the anhydrides of fatty acids into glyoxalines which contain the alkyl group of the fatty acid in position 2.

$\alpha^3$ -Dibenzamido- $\Delta^2$ -propylene is converted by acetic anhydride at  $180^\circ$  into 2:4(2:5)-dimethylglyoxaline, identified as the picrate, m. p.  $142^\circ$ . The action of propionic anhydride under similar conditions leads to the formation of 4(5)-methyl-2-ethylglyoxaline, hygroscopic crystals, m. p.  $45^\circ$  (oxalate, colourless leaflets, m. p.

145°; *picrate*, yellow prisms, m. p. 131°; *hydrochloride*, hygroscopic leaflets, m. p. 132°; *nitrate*, m. p. 129°).

4(5)-Ethylglyoxaline (cf. Kolshorn, A., 1904, i, 675) is converted by benzoyl chloride and sodium hydroxide into  $\alpha\beta$ -*dibenzamido*- $\Delta^a$ -*butylene*,  $\text{NHBz}\cdot\text{CH}\cdot\text{C}(\text{Et})\cdot\text{NHBz}$ , needles, m. p. 146°, which is transformed by acetic anhydride at 140° into 2-methyl-4(5)-ethylglyoxaline (*picrate*, yellow needles, m. p. 90–91°; *oxalate*, m. p. 141°).

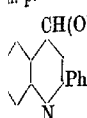

The glyoxaline obtained by Windaus and Ullrich (A., 1914, i, 662) by the action of ammonia on rhamnose is identified as 4(5)-methyl-5(4)-ethylglyoxaline. H. W.

**Preparation of Triarylmethane Dyestuffs.** BRITISH DYE STUFFS CORPORATION, LTD., JAMES BADDILEY, and ERNEST HARRY RODD (Brit. Pat. 189295).—New dyes of the triarylmethane series are obtained by condensing a 4 : 4'-dialkyldiamino-3 : 3'-dimethylbenzophenone with a suitable secondary or tertiary amine by warming with phosphoryl chloride with the addition of a neutral diluent if desired. These new basic products dye cotton mordanted with tannin-antimony valuable shades of bright reddish- to bluish-violet. Those containing phenyl, benzyl, or naphthyl residues substituted in the amino-groups can be sulphonated by warming with 20% fuming sulphuric acid, giving new acid dyes which dye wool level shades of violet. The ketones required for the synthesis may be obtained by boiling the corresponding thio-ketones with concentrated hydrochloric acid, and the latter are produced by the condensation of monoalkyl-*o*-toluidines with formaldehyde and converting the resulting diphenylmethane derivatives into thio-ketones by the process of Brit. Pat. 20615/14. 4 : 4'-*Diethyldiamino*-3 : 3'-*dimethylbenzophenone*, m. p. 165°, when condensed with ethyl-*o*-toluidine, gives the triphenylmethane dye in the form of a bronze-coloured paste which dyes mordanted cotton a reddish-violet. Bluer shades are obtained by condensing the ketone with benzylethylaniline or dibenzylaniline. G. F. M.

**Preparation of Aminopyridines.** CHEMISCHE FABRIK AUF ACTIEN (VOERM. E. SCHERING) (D.R.-P. 358397; from *Chem. Zentr.*, 1922, iv, 950).—Ammonia is allowed to act on pyridine or its homologues in the presence of alkali metals. For example, anhydrous pyridine at 80° is added to a suspension of finely divided sodium in toluene and anhydrous ammonia is passed in. After the sodium is used up the temperature is raised to 130° and so maintained until no more ammonia is absorbed. From the products of the reaction, by extracting with ether, distilling off the ether and fractionation of the residue, 2-*aminopyridine*, b. p. 103–110°/20 mm., 4 : 4'-*dipyridyl*, b. p. 173–180°/20 mm., and 4-*aminopyridine* are obtained. 6-*Amino*-2-*methylpyridine*, a yellow oil, b. p. 120–130°/20 mm., is similarly prepared from 2-methylpyridine ( $\alpha$ -picoline). G. W. R.

**Preparation of Amino-alcohols of the Quinoline Series.** SOCIETY FOR CHEMICAL INDUSTRY IN BASLE (Swiss Pats. 92001, 92607, 92608, and 92609; from *Chem. Zentr.*, 1922, iv, 950–951).—2-Phenyl-4-quinolyl methyl ketone is halogenated on the

methyl group and the halogen derivative allowed to react with primary or secondary amines. The *N*-alkyl-2-phenylquinolyl 4-aminomethyl ketone thus formed is reduced to the amino-alcohol. *Phenyl-4-quinolyl methyl ketone*, yellow crystals, m. p. 75°, is prepared by condensation of ethyl 2-phenylquinoline-4-carboxylate with ethyl acetate and elimination of carbon dioxide from the intermediate *ethyl 2-phenylquinoline-4-acetate*, m. p. 52–54°, or from *cyano-2-phenylquinoline* by Grignard's reaction. By the action of bromine on the ketone, *2-phenyl-4-quinolyl bromomethyl ketone hydrobromide* is obtained; it forms yellow crystals, m. p. about 25° (decomp.). The free *bromomethyl ketone* forms light yellow crystals, m. p. 91°. With dimethylamine it gives *2-phenyl-4-quinolyl 4-dimethylaminomethyl ketone*, which forms a *hydrochloride*, light yellow crystals, m. p. 208° (decomp.), and a *hydrobromide*, m. p. about 206°. Reduction of this compound gives  $\beta$ -dimethyl-

$\text{CH(OH)CH}_2\text{NMe}_2$  formula, a white, plastic mass. The *dihydrochloride* forms crystals, m. p. 175° (decomp.). *2-Phenyl-4-quinolyl diethylaminomethyl ketone* is similarly prepared; the *hydrobromide* forms yellow, felted needles, m. p. about 188° (decomp.). *2-Phenyl-4-quinolyl piperidinomethyl ketone* gives a *hydrochloride*, m. p. 235°, and a *hydrobromide*, m. p. about 241° (decomp.). *2-Phenyl-4-quinolyl dimethylaminomethyl ketone* forms yellow crystals, m. p. 123–125°. These ketones may be reduced to the corresponding amino-alcohols. *N*-Dimethylamino- $\alpha$ -2-phenyl-4-quinolyethanol gives a *dihydrochloride* which forms crystals, m. p. about 185°, with darkening.  $\beta$ -Piperidino- $\alpha$ -2-phenyl-4-quinolyethanol gives a *dihydrochloride*, m. p. about 99° (decomp.).  $\beta$ -Anilino- $\alpha$ -2-phenylquinolyethanol,

has m. p. 146°.

G. W. R.

**Preparation of a Primary Amino-alcohol of the Quinoline Series.** SOCIETY FOR CHEMICAL INDUSTRY IN BASLE (Swiss Pat. 2301; from *Chem. Zentr.*, 1922, iv, 951; cf. preceding abstract).—*2-Phenyl-4-quinolyl methyl ketone* is changed into its oximinomethyl ketone and this is submitted to reduction. *2-Phenyl-4-quinolyl oximinomethyl ketone* forms yellow crystals, m. p. 182° (decomp.). By reduction,  $\beta$ -amino- $\alpha$ -2-phenyl-4-quinolyethanol,

is obtained. It forms a *dihydrochloride*, colourless crystals, m. p. about 190° after softening at about 145°.

G. W. R.

**Reduction of 4:4'-Dipyridyl.** OTTO DIMROTH and FRITZ FRISTER (*Ber.*, 1922, 55, [B], 3693–3697).—The formation of 1:1'-diacetyldihydro-4:4'-dipyridyl by the action of acetic anhydride on the dark violet solution obtained by the reduction of 4:4'-dipyridyl with nascent hydrogen, has been described previously (Dimroth and Frister, *A.*, 1922, i, 678). It is now shown that the violet solution contains a semiquinonoid compound

of molar proportions of 4:4'-dipyridyl and 1:1'-dihydro-4:4'-dipyridyl, which has been isolated as the dihydrochloride, for which the name dipyridyl-violet chloride is proposed. The dye differs from other semiquinonoid substances in that the reduced half is quinonoid and the oxidised half has the aromatic constitution. 4:4'-Dipyridyl is obtained conveniently and in 90—95% yield by the action of oxygen on a suspension of 1:1'-diacetyl-tetrahydro-4:4'-dipyridyl in glacial acetic acid and subsequent addition of sodium hydroxide to the solution. Titration of an aqueous solution of the substance with chromous chloride solution in the absence of air shows that the dye is produced by the action of one equivalent of hydrogen on a molecule of dipyridyl and that further reduction is not caused by chromous chloride. The dye is isolated as a dark green, crystalline powder,  $C_{20}H_{20}N_4Cl_2$ , by the action of chromous chloride on a solution of dipyridyl in the presence of calcium chloride; the precipitated product is washed successively with water and alcohol in the absence of air, towards which it is unusually sensitive.

H. W.

**Syntheses in the Indole Group. II. The Influence of the Solvent on the Grignard Reaction.** RIKO MAJIMA and MUNIO KOTAKE (*Ber.*, 1922, **55**, [B], 3865—3872).—The unexpected differences observed in the production of indole-3-aldehyde from magnesium indolyl iodide and formic ester according as the reaction is effected in the presence of aliphatic or arylaliphatic ethers (Majima and Kotake, this vol., i, 156) has led the authors to examine possible further cases of this kind. Better yields of the products of the action of magnesium indolyl iodide on carbon dioxide, acetone, or benzaldehyde are obtained in the presence of anisole than in that of ethyl ether, whereas the reverse is the case when ethyl chloroformate, acetyl chloride, or chloroacetyl chloride is used.

Indole-3-carboxylic acid, m. p. 218—220°, is obtained by the action of carbon dioxide on magnesium indolyl iodide in anisole or ethyl ether. The reaction has been examined previously by Oddo (*A.*, 1911, i, 486), who has thus isolated indole-1-carboxylic acid, m. p. 108°; the cause of the discrepancy has not been elucidated. Magnesium indolyl iodide and acetone give di-3-indolyl-dimethylmethane, m. p. 163—165° (cf. Scholtz, *A.*, 1913, i, 520). Di-3-indolylphenylmethane,  $CHPh(CH<\overset{C_6H_5}{CH}>NH)_2$ , m. p. 149—152° (+0.5C<sub>6</sub>H<sub>6</sub>), m. p. 120—121°, is prepared from magnesium indolyl iodide and benzaldehyde; it is oxidised by ferric chloride in alcoholic solution to the red dye,

m. p. about 245—248°. Ethyl chloroformate and magnesium indolyl iodide give ethyl indole-3-carboxylate, colourless crystals, m. p. 118—119°; Oddo's observation (*loc. cit.*) that ethyl indole-2-carboxylate, m. p. 107°, is produced could not be confirmed. Acetyl chloride and magnesium indolyl iodide yield 3-indolyl

methyl ketone,  $\text{NH} \begin{smallmatrix} \text{C}_6\text{H}_5 \\ \text{CH} \end{smallmatrix} \text{C} \cdot \text{COMe}$ , m. p. 188—189° (oxime, m. p. 143—146°), identical with the products described by Oddo (*loc. cit.*). 3-Indolyl chloromethyl ketone forms small, rhombic crystals, m. p. 212—214°. H. W.

**Isomeric Relationships in the Pyrazole Series.** K. von AUWERS and H. BROCHE (*Ber.*, 1922, 55, [B], 3880—3911).—An examination has been made of the possibility of the existence of isomerides of the types  $\text{RN} \begin{smallmatrix} \text{CH} \cdot \text{CH} \\ \text{N} = \text{CH} \end{smallmatrix}$  and  $\text{RN} \begin{smallmatrix} \text{N} - \text{CH} \\ \text{CH} \cdot \text{CH} \end{smallmatrix}$ , in the pyrazole series analogous to those observed with the closely related indazoles,  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \\ \text{NR} \end{smallmatrix} \text{N}$  and  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CH} \\ \text{N} \end{smallmatrix} \text{NR}$ . The alkyl and

phenyl derivatives of 3-methyl- and 3:5-dimethyl-pyrazole have been investigated, but evidence of existence of isomerides of the expected type has not been obtained. The observations which have been made throw doubt on the identity of 3- and 5-derivatives of pyrazole as assumed by Knorr and other investigators.

3-Methylpyrazole is converted by an equivalent amount of methyl iodide in ethereal solution at 120° into 1:3-dimethylpyrazole (*picrate*, m. p. 172.5°; cf. Jowett and Potter, T., 1903, 83, 467), a portion of the base remaining, however, unchanged. The same substances are obtained by boiling 3-methylpyrazole with methyl iodide and sodium methoxide in methyl alcoholic solution. 1:3-Dimethylpyrazole, b. p. 141—142°, is readily isolated in the homogeneous condition by the dry distillation of its methiodide, m. p. 255—256°. In a similar manner, the ethylation of 3-methylpyrazole with ethyl bromide at 100° or in the presence of alkali gives 3-methyl-1-ethylpyrazole, a colourless liquid, b. p. 132°/atmospheric pressure (*picrate*, slender yellow needles, m. p. 141°); the formation of quaternary salts in this case is much less pronounced than when methyl iodide is used. The products of the benzylation of 3-methylpyrazole are readily separated by taking advantage of the insolubility of the benzylated compounds in water in which the original material and the pyrazolium salt are soluble; experiments in the presence or absence of alkali yielded 1-benzyl-3-methylpyrazole, a colourless liquid with an odour of hyacinths, b. p. 140—141°/14 mm. (*picrate*, slender, yellow needles, m. p. 112.5—113.5°). In contrast to the indazoles, 3-methylpyrazole, when alkylated by different methods, gives only one definite substitution product. The proof that this is a 1:3- (and not a 1:5-) derivative is deduced in the following manner. The benzoic ester of hydroxymethyleneacetone,  $\text{CH}_3\text{CO} \cdot \text{CH} \cdot \text{CH} \cdot \text{OBz}$ , colourless crystals, m. p. 91—92°, prepared by the action of benzoyl chloride on a suspension of the sodium compound of hydroxymethyleneacetone in pyridine and anhydrous ether) is condensed with methylhydrazine and benzylhydrazine, whereby dimethyl- and benzylmethyl-pyrazoles are obtained identical with the products described above; unfortunately, it was not found possible to isolate the intermediately formed benzoates, but the mode of formation

leaves practically no doubt that 1:3-derivatives are formed. Under similar conditions, phenylhydrazine gives 1-phenyl-3-methylpyrazole, m. p. 37°. The condensation of hydroxymethyleneacetone with methylhydrazine leads to the production of 1:3-dimethylpyrazole without any isomeric substance, and differs therefore from the action with phenylhydrazine, which yields a mixture of 1:3- and 1:5-compounds.

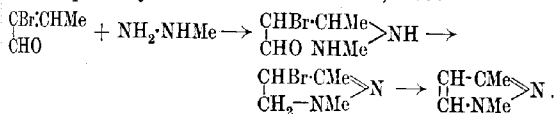

The observations have been extended to 3:5-dimethylpyrazole,  $\text{NH} \begin{smallmatrix} \text{CH} \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \text{CH} \\ \text{CH} \end{smallmatrix} \text{Me}$ , the symmetrical structure of which excludes the formation of structurally isomeric 3- and 5-derivatives; any case of isomerism must therefore be due to difference in a ring structure, since the production of 4-derivatives is excluded. It is converted by methyl iodide in the presence of alkali into 1:3:5-trimethylpyrazole, the picrate of which has m. p. 144–145°, whereas Knorr gives 131–133°. Similarly, 3:5-dimethylpyrazole and benzyl chloride at 170° give exclusively 1-benzyl-3:5-dimethylpyrazole, a colourless liquid, b. p. 144–146/10 mm. (picrate, lustrous, greenish-yellow needles, m. p. 126.5–127.5°). The latter compound is also produced by the action of acetylacetone on benzylhydrazine, although in this case the primary production of a three-membered ring might be expected. Finally, 1-phenyl-3:5-dimethylpyrazole has been prepared by the action of phenylhydrazine on acetylacetone and methyl  $\alpha$ -bromopropenyl ketone,  $\text{CHMe}:\text{CBr}:\text{COMe}$ , respectively; the compound obtained in either case gives a picrate, m. p. 101°, and there is no evidence of the production of an isomeric compound.

From the foregoing it appears therefore that cases of isomerism due to the different structure of the ring are not found in the cases of alkylated and arylated pyrazoles. It is, however, still more remarkable that the number of position isomeric alkylpyrazoles is smaller than would be expected from theoretical considerations since 1:3-derivatives are frequently formed exclusively when mixtures of them with 1:5-compounds or when the latter alone would be normally expected. In the hope that the reactions in the pyrazole series would resemble those in the indazole group, an examination of the effect of heat on pyrazolium salts has been made. 1-Phenyl-3-methylpyrazole methiodide, m. p. 144°, and 1-phenyl-5-methylpyrazole methiodide, m. p. 282°, lose methyl iodide when subjected to dry distillation and re-form 1-phenyl-3-methylpyrazole and 1-phenyl-5-methylpyrazole, respectively. Contrary to expectation, however, pure 1:3-dimethylpyrazole and 3-methyl-1-ethylpyrazole are obtained from 1-benzyl-3-methylpyrazole methiodide, m. p. 153–154°, and 1-benzyl-3-methylpyrazole ethiodide, colourless prisms, m. p. 149.5–150.5°. The formation of 1:3- instead of 1:5-compounds discloses a surprising atomic

migration in accordance with the scheme  $\begin{smallmatrix} \text{CH} & \text{CH} \\ | & | \\ \text{CH} \cdot \text{N}(\text{C}_6\text{H}_5) & \text{N} \end{smallmatrix} \begin{smallmatrix} \text{Me} \\ \text{Me}(\text{Et}) \end{smallmatrix} \xrightarrow{+ \text{C}_2\text{H}_5\text{I}} \begin{smallmatrix} \text{CH} & \text{CH} \\ | & | \\ \text{CH} & \text{CH} \end{smallmatrix} \begin{smallmatrix} \text{Me} \\ \text{Me}(\text{Et}) \end{smallmatrix} \begin{smallmatrix} \text{N} \\ \text{N} \end{smallmatrix} \begin{smallmatrix} \text{Me} \\ \text{Me}(\text{Et}) \end{smallmatrix}$ . The im-

portance of the observation has caused special attention to be directed to the constitution of the pyrazolium salts. The possibility that, contrary to rule, the addition of alkyl iodide occurs at the nitrogen atom which is already attached to an alkyl group is excluded by the observation that 1-benzyl-3-methylpyrazole methiodide differs from 1:3-dimethylpyrazole benzyl iodide, colourless leaflets, m. p. 167° (corresponding *picrate*, flat, yellow needles, m. p. 126°). The further possibility that the difference in the two iodides is due to the different spatial arrangement of the substituents around the same nitrogen atom and not to structural differences is improbable, and is more definitely excluded by the apparent impossibility of effecting their mutual interconversion. The wandering of alkyl groups during the fission of certain pyrazolium salts must therefore be regarded as established. Nevertheless, it does not follow that 1:5-dialkylpyrazoles are incapable of existence, since the high temperature involved in the fission can greatly facilitate the transformation of the primary products of the change into the 1:3-isomerides.

The synthesis of 1:5-dialkylpyrazoles has therefore been attempted under conditions which are less likely to involve transformation. The action of phenylhydrazine on  $\alpha$ -bromocrotonaldehyde leads to the formation of 1-phenyl-5-methylpyrazone (cf. Vignier, A., 1913, i, 444), but under precisely similar conditions, methylhydrazine gives 1:5-dimethylpyrazole in good yield. A possible explanation of the difference in the reaction lies in the assumption that the alkylhydrazine, unlike the aryl compound, becomes primarily added at the double bond, thus:

This hypothesis is shown to be improbable in the following manner.  $\beta$ -Keto-*n*-butyl alcohol condenses with methylhydrazine sulphate in aqueous solution in the presence of acetic acid and sodium

acetate to yield 1:3-dimethylpyrazoline,  $\begin{array}{l} \text{CH}_2\cdot\text{CH}_2 \\ \text{CMe=N} \end{array} \text{>NMe}$ , a colour-

less liquid, b. p. 127–129° (*picrate*, yellow needles, m. p. 131.5–132.5°) (1-phenyl-3-methylpyrazoline, m. p. 71–72°, is prepared similarly from phenylhydrazine). If crotonaldehyde, which may be assumed to react in the same manner as its bromo-derivative, is similarly condensed with methylhydrazine, it must yield 1:3-dimethylpyrazoline if the hydrazine is added initially at the double bond and 1:5-dimethylpyrazoline if the initial reaction occurs at the aldehyde group. It is found that the compound which is produced is not identical with that derived from  $\beta$ -keto-*n*-butyl alcohol, and hence must be regarded as 1:5-dimethylpyrazoline,  $\begin{array}{l} \text{CH}_2\cdot\text{CHMe} \\ \text{CH=N} \end{array} \text{>NMe}$ ; it is a colourless, very hygroscopic liquid, b. p. 124–125°, which gives a *picrate*, thin, golden-yellow leaflets,

m. p. 113–114°. It must therefore be considered that the production of 1:3-dimethylpyrazole from methylhydrazine and bromocrotonaldehyde instead of the expected 1:5-derivative is actually due to atomic wandering.

Attempts to convert 1:3- and 1:5-dimethylpyrazolines into the corresponding pyrazoles by cautious oxidation with bromine led to remarkable results. The 1:3-compound is transformed smoothly into 1:3-dimethylpyrazole; the 1:5-derivative is largely resinified but is partly converted into 1:3-dimethylpyrazole.

It therefore appears that, under usual conditions, 1:5-dimethylpyrazole (and presumably other 1:5-dialkylpyrazoles) are incapable of existence, whereas 1-phenyl-3-methylpyrazole and 1-phenyl-5-methylpyrazole are stable substances.

Knorr's conception that the pyrazole molecule is symmetrically constituted owing to the oscillation of the double bonds and of the hydrogen atom united to the nitrogen:

$$\begin{array}{c} \text{CH} \cdot \text{NH} \\ \text{CH} \cdot \text{CH} \end{array} \gg \text{N} \rightleftharpoons$$

$\begin{array}{c} \text{CH} = \text{N} \\ \text{CH} \cdot \text{CH} \end{array} \gg \text{NH}$ , can scarcely be extended to the alkyl derivatives

of pyrazole, since a continuous oscillation of an alkyl group between two nitrogen atoms is contrary to all experience of tautomerism and the firmness of attachment of alkyl groups. The authors do not regard the production of 1:3-dialkylpyrazoles in place of the expected 1:5-derivatives as due to the identity of the two series of compounds in consequence of "mobile" double bonds and oscillatory atomic displacements; it is caused by the great instability of the 1:5-derivatives which immediately after formation become

isomerised in accordance with the scheme:

$$\begin{array}{c} \text{CH} = \text{N} \\ \text{CH} \cdot \text{CR} \end{array} \gg \text{NR} \rightarrow$$

$\begin{array}{c} \text{CH} \cdot \text{NR} \\ \text{CH} \cdot \text{CR} \end{array} \gg \text{N}$ .

H. W.

**The Polymorphism of Antipyrine, Vanillin, and the Erythritols.** PAUL GAUBERT (*Compt. rend.*, 1922, 175, 1414–1417).—In general, a substance which can be superfused, or, better, can pass into the amorphous state, will occur in several crystalline forms depending on the temperature. This appearance may be favoured by the presence of some impurity or sometimes by the more or less prolonged heating of the substance at a temperature above its melting point. In this manner, it is shown that antipyrine melted on a glass plate may occur in three crystalline modifications, vanillin may give four crystalline modifications, and the erythritols two crystalline forms. The conditions for obtaining these modifications and the forms obtained are detailed.

W. G.

**Preparation of a Derivative of Barbituric Acid Soluble in Water.** HERMANN STAUDINGER (Swiss Pat. 91561; from *Chem. Zentr.*, 1922, iv, 840).—Diallylbarbituric acid or ethylallylbarbituric acid is treated with ozone and the ozonide is changed into the corresponding carboxylic acid. Diallylbarbituric acid gives a crystalline ozonide which is decomposed by heating over a water-bath with

formation of a *dicarboxylic acid* (I), colourless crystals, m. p. 280° (decomp.). Ethylallylbarbituric acid gives similarly a *monocarboxylic acid* (II) which forms colourless crystals, m. p. 280—281°:

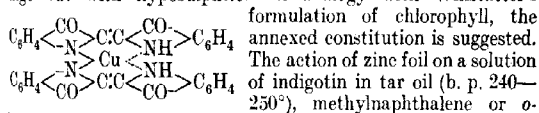

The compounds have therapeutic uses and serve as intermediates for the preparation of other barbituric acid derivatives.

G. W. R.

**Preparation of a Compound of 5-isoPropyl-5-allylbarbituric Acid.** F. HOFFMANN LA ROCHE & Co. (Brit. Pat. 188251).—5-isoPropyl-5-allylbarbituric acid when fused in approximately molecular proportions with 4-dimethylamino-1-phenyl-2:3-dimethyl-5-pyrazolone form as double compound which is apparently homogeneous, and melts sharply at 92—93°. It is yellow in colour and dissolves in hydrocarbons to a deep yellow solution. Water and other solvents containing hydroxyl give only slightly yellow solutions, indicating that in these solvents the compound is resolved into its colourless components to a considerable extent. The compound is valuable therapeutically, as it combines the soporific action of the barbituric acid with the analgesic action of the pyrazolone, and can therefore partly replace the opiates.

G. F. M.

**Complex Metallic Compounds of Indigotin.** I. K. KUNZ *Ber.*, 1922, 55, [B], 3688—3691).—During the course of experiments on the production of 1:1-diphenylindigotin (Friedländer and Kunz, A., 1922, i, 765), it was observed that boiling solutions of indigotin in *o*-nitrochlorobenzene are rapidly decolorised by cuprous chloride and sodium acetate or copper powder. A similar change is now shown to occur in other solvents of high boiling point. It leads to the formation of the compound,  $\text{C}_{32}\text{H}_{18}\text{O}_4\text{N}_4\text{Cu}$ , which is rapidly decomposed by mineral acids and gives a normal indigo vat with hyposulphite. In analogy with Willstätter's

formulation of chlorophyll, the annexed constitution is suggested. The action of zinc foil on a solution of indigotin in tar oil (b. p. 240—250°), methylnaphthalene or *o*-nitrochlorobenzene leads to the formation of a zinc compound,  $\frac{1}{2}\text{C}_{32}\text{H}_{18}\text{O}_4\text{N}_4\text{Zn}$ , black, lustrous prisms, which, unlike the copper compound, is rapidly hydrolysed by warm water with production of indigotin. A crystalline *nickel* derivative has also been prepared by the use of nickel sulphate and sodium acetate, but it has not yet been found possible to prepare a magnesium compound.

H. W.

**Benzbisthiazoles.** II. STEPHEN RATHBONE HOLDEN EDGE *T.*, 1923, 123, 153—156).

**Syntheses in the Indole Group. I. A New Synthesis of  $\tau$ -Tryptophan.** RIKO MAJIMA and MUNIO KOTAKE (*Ber.*, 1922,

55, [B], 3859—3865).—Indole-3-aldehyde,  $C_6H_4 \begin{smallmatrix} C(CHO) \\ \diagup \quad \diagdown \\ NH \end{smallmatrix} > CH_3$ ,

m. p. 193—195°, is conveniently prepared in 40% yield by the successive action of indole and formic ester on a solution of magnesium ethyl iodide in anisole which is cooled in a mixture of ice and salt; in ethereal solution only traces of the aldehyde are formed (cf. Alessandri and Florence, A., 1915, i, 452). Phenetole may replace anisole, and ethoxymethylethaniline may take the place of formic ester, but the yields are thereby somewhat reduced; amyl ether is as unsuitable as ethyl ether. The aldehyde is heated with hydantoin, anhydrous sodium acetate, and acetic anhydride at 106—108°, and the product is treated with aqueous sodium hydroxide solution, whereby 3-indolyldenehydantoin,

m. p. about 320°, decomp. 325°, is formed, the yield being 46.6% of that theoretically possible. 1-Acetylindole-3-aldehyde is obtained as a by-product of the action; it therefore appears probable that it is this derivative which actually undergoes condensation and that acetyl-3-indolyldenehydantoin is hydrolysed by the treatment with sodium hydroxide; the inefficiency of acetic acid and sodium acetate as condensing agents thus receives an explanation. 3-Indolyldenehydantoin is reduced by sodium amalgam in alkaline solution to  $\omega$ -hydantylscatole,

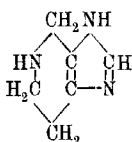

colourless needles, m. p. 220—221°. The latter is hydrolysed by aqueous barium hydroxide solution at 108° to  $\tau$ -tryptophan,

285° after becoming discoloured at 250°. As by-product, a substance,  $C_{12}H_{13}O_3N_3$ , leaflets, m. p. 207° (decomp.), is isolated.

**Preparation of a Condensation Product from  $\beta$ -Iminazolyethylamine [4- $\beta$ -Aminoethylglyoxaline].** SOCIETY FOR CHEMICAL INDUSTRY IN BASLE (Swiss Pat. 92297; from *Chem. Zentr.*, 1922, iv, 890).—When formaldehyde or, preferably, methylal is added slowly to a suspension of

line and has m. p. 249°.

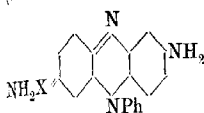

4- $\beta$ -aminoethylglyoxaline in fuming hydrochloric acid at 100° and the mixture heated for several hours in a reflux apparatus,  $\beta$ -imidazolydisopiperidine [tetrahydro-1:3:6-benzotriazole] (annexed formula) is formed. The hydrochloride is crystalline and has m. p. 249°.

G. W. R.

**Determination of the Constitution of Colouring Matters from their Absorption Spectra. IV.** F. KEHRMANN and M. SANDOZ (*Helv. Chim. Acta*, 1922, 5, 895—905; cf. A., 1921, i, 276).—In continuation of previous work, the absorption spectra of

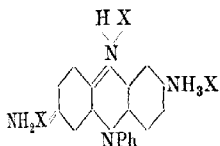

salts of diamino-derivatives of methyl- and phenyl-phenazine have been examined. The introduction of a second symmetrical amino-group into the monoaminomethylphenazine previously described (*loc. cit.*), lightens the colour of the mono-acid salt from cherry-red to orange-red. The absorption maxima are at  $\lambda$  530 and  $\lambda$  483. Introduction of a phenyl group into each amino-group deepens the shade to bluish-violet, and there is now only one absorption maximum, at  $\lambda$  572. The corresponding ditolyl derivative has an absorption maximum at  $\lambda$  580.

The monoacid salts of the diaminophenylphenazines chosen for examination were the perchlorates, on account of their great stability. The mono-acid salt of 2:7-diaminophenylphenazine (annexed formula) is blue, and to it may be ascribed the same

para-quinonoid structure as to *aposafranine*, which is violet-red. The di-acid salt is red, corresponding very closely with *aposafranine*, from which it is inferred that the second amino-group has been neutralised but that no change in the

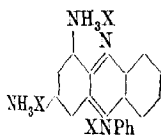

disposition of the double bonds has occurred. When the diaminophenylphenazonium perchlorate is dissolved in concentrated sulphuric acid, the colour of the solution is green. The colour is due

to the tri-acid salt (annexed formula) and is similar to that of the di-acid salt of *aposafranine*. Again there is no change of structure, and it is interesting to note the colour-deepening effect of the fixation of an equivalent of acid by a doubly-linked atom forming part of the chromogen. Finally,

in fuming sulphuric acid the colour is reddish-brown, resembling the di-acid salt of phenylphenazine. This salt must have an ortho-quinonoid structure.

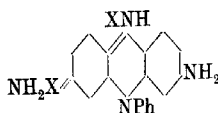

The perchlorate of 1:3-diaminophenylphenazine is green in water, yellowish-green in alcohol, approaching a yellow of the second order. Although the amino-group in position 1 has a considerable colour-deepening effect, the structure is still probably paraquinonoid. The di-acid salt of this compound resembles

*aposafranine*, as in the case of the 2:7-isomeride, but the tri-acid salt, obtained by direct solution in concentrated sulphuric acid, is not green, but yellow, resembling the mono-acid salt of phenylphenazine. The structure of this salt must therefore be orthoquinonoid (annexed formula). When the perchlorate is dissolved in fuming sulphuric acid, the reddish-brown colour of the tetra-acid salt is obtained.

The perchlorate of the third isomeride, *phenosafranine*, is red with an orange fluorescence in solution. Here again, as with methylphenazine, the second symmetrical amino-group brightens the shade whilst the colour intensity is increased. The di-acid

salt is blue, indicating that the second acid equivalent is combined with chromogenic nitrogen (annexed formula). The tri-acid salt

is green, resembling, as expected, the di-acid salt of *aposafranine*. The tetra-acid salt is the normal reddish-brown. It is concluded that all the observed facts can be explained if it is granted that two states, ortho- and para-quinonoid, are possible in this series. It is further shown briefly that acetylation of an amino-group in this series has a similar effect on its auxochromic properties to neutralisation of the group with acid.

E. H. R.

**The Solubility of the Salts of Uric Acid.** GEORG BARKAN (*Z. Biol.*, 1922, **76**, 257—266).—The solubility of freshly precipitated amorphous sodium urate ( $C_5H_3O_3N_4Na \cdot H_2O$ ) at  $18^\circ$  is 2.03 g. or  $9.8 \times 10^{-3}$  gram-molecules per litre. On keeping, or more particularly on stirring in contact with its solution, the solubility decreases, and approaches that of the crystalline form.

W. O. K.

**Oxidation of Benzeneazoresorcinol.** DINO BIGIARI and GIULIO GIANNINI (*Atti R. Accad. Lincei*, 1922, [v], **31**, ii, 109—116).—Of the two possible diacetyl derivatives,

and ( $\beta$ )  $C_6H_5 \cdot N \cdot NO \cdot C_6H_3(OAc)_2$ , obtainable by the oxidation of the diacetyl compound of benzeneazoresorcinol by means of hydrogen peroxide, only the latter is actually obtained, the  $\alpha$ -form probably undergoing further oxidation.

in red granules, m. p.  $144^\circ$ , giving a chestnut-yellow powder. The *dibenzoyl* derivative forms pale yellow needles, m. p.  $113^\circ$ , and the *diacetyl* derivative, long, pale yellow, silky needles, m. p.  $102^\circ$ .

4-Benzeneazoxy-2:6-dibromoresorcinol,  $C_6H_5 \cdot N \cdot NO \cdot C_6H_3Br_2(OH)_2$ , crystallises in transparent, greenish-yellow cubes, m. p.  $153^\circ$ , and yields aniline when reduced by means of zinc and acetic acid.

forms long, red needles, m. p.  $229^\circ$  (decomp.), and gives 2:4-dibromoaniline when reduced by means of tin and hydrochloric acid.

is a red compound, m. p.  $220^\circ$ .

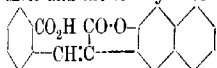

When treated with alcoholic potassium hydroxide, the diacetyl derivative of  $\beta$ -benzeneazoxyresorcinol yields a dark red compound, m. p. about  $190^\circ$ , which has not yet been characterised.

T. H. P.

**Oxidation of Benzeneazonnaphthols.** I. DINO BIGIARI and RENATO CERCHIAI (*Atti R. Accad. Lincei*, 1922, [v], **31**, ii, 27—30).—Owing to the divergent behaviour towards alkali shown by the three isomeric benzeneazonnaphthols, a phenylhydrazonic constitution is attributed to 1-benzeneazo-2-naphthol, whilst 4-benzeneazo-1-naphthol and 2-benzeneazo-1-naphthol are considered to possess the ordinary hydroxylic formulæ (Goldschmidt and Brubacher, A., 1891, 1209; Willstätter and Parnas, A., 1907, i, 425, 1056). Marked differences are found also in the behaviour of these compounds towards 30% hydrogen peroxide solution and acetic acid.

Thus, under these conditions, 1-benzeneazo-2-naphthol and also its acetyl-derivative undergo slow oxidation in the cold to carboxycinnamic acid,  $\text{CO}_2\text{H}\cdot\text{C}_6\text{H}_4\cdot\text{CH}:\text{CH}\cdot\text{CO}_2\text{H}$ , m. p.  $200^\circ$ , whilst in the hot they yield the isomeric dihydroisocoumarincarboxylic acid,  $\text{C}_6\text{H}_4\begin{smallmatrix} \text{CO-O} \\ \diagup \end{smallmatrix} \text{CH}_2\begin{smallmatrix} \diagdown \\ \text{CH}\cdot\text{CO}_2\text{H} \end{smallmatrix}$ , m. p.  $153^\circ$ , which is also obtained when carboxycinnamic acid is fused for a few moments.

Similar oxidation of  $\beta$ -naphthol yields the products obtained by Ehrlich by the action of permanganate (A., 1889, 1001), namely: (1) Carboxycinnamic acid, for which, however, this author gave m. p.  $183^\circ$  instead of  $200^\circ$ ; (2) an acid,  $\text{C}_{20}\text{H}_{12}\text{O}_4$ , m. p.  $281^\circ$ , which, although regarded by Ehrlich as dibasic, gives only mono-silver and monoethyl derivatives, and has probably the structure

. This acid reduces permanganate, but not so rapidly as does carboxycinnamic acid.

T. H. P.

**Reduction of Ethyl Diazobenzylideneglucuronate.** P. A. LEVENE (*J. Biol. Chem.*, 1922, **54**, 809—813).—When reduced with aluminium amalgam in isopropyl-alcoholic solution, ethyl diazobenzylideneglucuronate yields a mixture of ethyl benzylidenedeoxyglucuronate and ethyl benzylidene chitosamate. The former product is identical with that previously obtained (A., 1922, i, 1028) by reduction of ethyl benzylidene- $\alpha$ -3-anhydromannonate; the latter was not isolated, but was identified by hydrolysis into chitosamic acid. The reduction apparently takes place asymmetrically, for no trace of an epimeride of chitosamic acid can be detected. That the deoxy-compound is not produced through the intermediate formation of an unsaturated compound is shown by the fact that the amide of benzylidene- $\alpha$ -3-anhydromannonic acid is unchanged when submitted to similar treatment.

E. S.

**The Formation of Aromatic Thiocyanates by the Diazo-reaction.** A. KORCZYNSKI [with J. KNIATOWNA and F. KAMINSKI] (*Bull. Soc. chim.*, 1922, [iv], **31**, 1179—1185).—In the transformation of *o*-nitrodiazobenzene thiocyanate into *o*-nitrophenyl thiocyanate under the catalytic influence of a metallic thiocyanate, the yield obtained depends on the metal of which a salt is used and on the temperature, being greater, in the majority of cases

studied, at 15–20° than at 60–70°. The most effective catalysts of the substances used are the thiocyanates of iron and tungsten.

H. J. E.

**The Tryptophan Content of some Proteins.** CLARENCE E. MAY and EMBREE R. ROSE (*J. Biol. Chem.*, 1922, **54**, 213–216).—The colour which tryptophan yields with Ehrlich's reagent has been utilised for the estimation. The protein (0.05 to 1 g.) is added to a mixture of concentrated hydrochloric acid (50 c.c.), water (50 c.c.), and a 5% solution of *p*-dimethylaminobenzaldehyde in 10% sulphuric acid (1 c.c.). It is then incubated at 35° for twenty-four hours, left at the ordinary temperature for at least twenty-four hours, and the colour then compared with a casein standard. It is assumed that casein yields 1.5% of tryptophan. Application of the method to a number of proteins yielded the following values: lactalbumin 2.4, gliadin 1.05, glutenin 1.80, edestin 1.5, glycinin 1.65, ovovitellin 1.74, egg-albumin 1.11, phaseolin 0.80, maize gluten 1.08, legumin (vetch) 1.05%. No colour developed in the case of zein and gelatin.

E. S.

**The Isoelectric Point of Globin.** SHUNGO OSATO (*Biochem. Z.*, 1922, **132**, 485–487).—The isoelectric point of globin from blood-corpuscles is found by the precipitation method to be at  $P_H$  8.1.

W. O. K.

**I. The Preparation of Nucleic Acid from the Nucleoprotein of Tubercle Bacilli (Tuberculinic Acid). II. The Pyrimidines contained in Tuberculinic Acid, the Nucleic Acid of Tubercle Bacilli.** TREAT B. JOHNSON and ELMER B. BROWN (*J. Biol. Chem.*, 1922, **54**, 721–730, 731–737).—I. A method is described for the preparation of tuberculinic acid from tubercle bacilli (cf. also Ruppel, A., 1899, ii, 237; Levene, A., 1901, i, 299). The protein which remains after removal of this nucleic acid has been analysed for nitrogen distribution with the following results: amide-N 11.83, humin-N 4.11, cystine-N 1.26, arginine-N 10.63, histidine-N 11.48, lysine-N 3.69, monoamino-N 47.39, non-amino-N 9.34%. Tryptophan was also present.

II. Cytosine and thymine have been isolated from the products of hydrolysis of tuberculinic acid; the presence of uracil could not be detected.

E. S.

**The Results and Aims of General Enzyme Chemistry.** H. VON EULER (*Ber.*, 1922, **55**, [B], 3583–3600).—A lecture delivered at the centenary of the *Versammlung Deutscher Naturforscher und Aerzte*.

H. W.

**The Isolation of Enzymes.** RICHARD WILLSTÄTTER (*Ber.*, 1922, **55**, [B], 3601–3623).—A lecture delivered at the centenary of the *Versammlung Deutscher Naturforscher und Aerzte*.

H. W.

**Saccharase.** E. CANALS (*Bull. Soc. chim.*, 1922, [iv], **31**, 1333–1341; cf. A., 1922, i, 1075).—The author traces a relationship between the magnesium and phosphate content of saccharases of various origins, and their respective diastatic powers, which

seems to some extent to support the opinion of Salkowski that invertase is the magnesium salt of a nitrogenous phosphated acid. A direct relationship cannot be traced, however, between the total magnesium and phosphoric acid content and the diastatic power, since, if the preparation is purified by dialysis, the diastatic power is enhanced whilst there is a loss of about 40% of Mg and 8% of  $P_2O_5$ , and all the magnesium and phosphoric acid of the saccharase is therefore not essential for the hydrolysing activity. Purification by precipitation with alcohol results in a similar loss in magnesium and an even greater loss in phosphoric acid, and in this case the diastatic power is greatly diminished, owing probably to a profound modification of the colloidal system of the enzyme by this treatment. Alcoholic precipitation is therefore not suitable for the purification of saccharase. It is observed that the magnesium of the saccharase dialyses less easily, and is less readily separated by alcoholic precipitation than the phosphate, and it would therefore seem to enter to a greater extent into the constitution of the micelle.

G. F. M.

**The Influence of Neutral Alkali-metal Salts on Diastatic Ferment.** V. AMANDUS HAHN and HUGO MEYER (*Z. Biol.*, 1922, 76, 227—246).—Purified diastase from commercial pancreatin "Rhenania" is influenced as regards its activity by the presence of neutral salts of the alkali metals similarly to saliva diastase, and to unpurified pancreatin. The optimum  $P_H$  depends on the buffer solution used, being 7.2 with a phosphate mixture and 5.6 with an acetate mixture, resembling saliva which has corresponding optimum at  $P_H$  6.6 and  $P_H$  5.6. The influence of neutral salts is much more marked with acetate buffer mixtures than with phosphate buffer mixtures. In both cases the effect is to increase the optimum  $P_H$ .

W. O. K.

**Arseno-metallic Compounds. II. Isomeric Silver Salvarsans.** A. BINZ and W. H. LUDWIG (*Ber.*, 1922, 55, [B], 3826—3831).—The silver complex of silver salvarsan has been considered by Ehrlich and Karrer (*A.*, 1916, i, 95) to be co-ordinatively attached to the arsenic atom and by Binz, Bauer, and Hallstein (*A.*, 1920, i, 401) as united by the residual affinity of the nitrogen atom. The isolation of two isomeric silver salvarsans apparently justifies both formulæ. At present, the allotment of the structure to the isomeride is somewhat arbitrary and is due to the fact that one form is lighter in colour than the other and resembles to this extent the complex compounds containing silver and nitrogen, but not arsenic.

*Silver salvarsan I*,  $NH_2 \cdot C_6H_3(OH) \cdot As \cdot As \cdot C_6H_3(OH) \cdot NH_2 \dots AgOH$ , is obtained by adding sodium carbonate solution to salvarsan and silver nitrate dissolved in water; it is insoluble in sodium carbonate and stable towards reduction with hypophosphorous acid. It dissolves in sodium hydroxide solution with the dark brown colour of technical silver salvarsan, and from the solution carbon dioxide precipitates the *isomeride*,

a dark brown substance which dissolves in sodium carbonate solution and is reduced by hypophosphorous acid. Silver salvarsan I is rapidly converted by hydrochloric acid into the compound  $\text{NH}_2\cdot\text{C}_6\text{H}_3(\text{OH})\cdot\text{As}\cdot\text{As}\cdot\text{C}_6\text{H}_3(\text{OH})\cdot\text{NH}_2\cdots\text{AgCl}$ , a pale yellow powder. The dark brown isomeride II appears to be unaffected by similar treatment after several hours, but gradually becomes converted into the chloride just described, the formation of which from the chloride,  $\text{NH}_2\cdot\text{C}_6\text{H}_3(\text{OH})\cdot\text{As}\cdot\text{As}(\cdots\text{AgCl})\cdot\text{C}_6\text{H}_3(\text{OH})\cdot\text{NH}_2$ , takes place very slowly in comparison with the change in the reverse direction in alkaline solution. The same change occurs when solutions of technical silver salvarsan are treated with hydrochloric acid, the brown colour in this case persisting for a considerable time and gradually giving place to a pale yellow precipitate. H. W.

### Physiological Chemistry.

#### Respiratory Exchange in Fresh-water Fish. IV. Further Comparison of Gold-fish and Trout. JOHN ADDYMAN GARDNER

and GEORGE KING (*Biochem. J.*, 1922, **16**, 729—735).—The oxygen tension at the asphyxial point at various temperatures in the case of the gold-fish has been determined. This fish can stand much lower oxygen tensions for any temperature than the trout. The difference is more marked at low temperatures. Trout kept at a low temperature corresponding with a state of hibernation showed a higher glycogen content than control fish kept at higher temperatures, which is consonant with the respiratory coefficients obtained for these fish. Glycogen estimation in the case of the gold-fish yielded results which were in conformity with the low level of their metabolism. S. S. Z.

#### Respiratory Exchange in Fresh-water Fish. V. Eels.

JOHN ADDYMAN GARDNER and GEORGE KING (*Biochem. J.*, 1922, **16**, 736—738).—Eels live at a much lower plane of metabolism than trout. At medium temperatures trout use about four times as much oxygen as eels, and at low temperatures 10—12 times as much. S. S. Z.

**Influence of the Introduction of Water on Blood Concentration Induced by Deprivation of Water.** FRANK P. UNDERHILL and ROBERT KAPSINOW (*J. Biol. Chem.*, 1922, **54**, 459—464).—The experiments were performed on dogs. Deprivation of water for short intervals produced an increased blood concentration which rapidly returned to approximately the normal on administration of water. E. S.

**Gas and Electrolyte Equilibria in the Blood. III. The Alkali-binding and Buffer Values of Oxyhæmoglobin and Reduced Hæmoglobin.** DONALD D. VAN SLYKE, A. BAIRD HASTINGS, MICHAEL HEIDELBERGER, and JAMES M. NEILL (*J. Biol. Chem.*, 1922, **54**, 481—506).—The technique previously developed

(A., 1922, i, 1207) has been used to determine the amount of alkali bound both by recrystallised horse oxyhæmoglobin (Heidelberger, A., 1922, i, 962) and by reduced hæmoglobin when under physiological conditions of concentration, carbon dioxide tension, and  $P_{H_2}$  value. At  $P_{H_2}$  7.4 one gram-molecule of oxyhæmoglobin binds  $2.15 \pm 0.10$  equivalents of alkali (sodium) whilst the corresponding figure for reduced hæmoglobin is  $1.47 \pm 0.08$ . The change of one mol. of reduced hæmoglobin to oxyhæmoglobin thus enables it to combine with an additional  $0.68 \pm 0.10$  equivalent of alkali. At intermediate points the increase in base bound is directly proportional to the increase in oxygen content, thus agreeing with Henderson's theory (A., 1921, i, 473) and with the assumption originally made by Christiansen, Douglas, and Haldane (A., 1914, i, 1012). The molecular buffer values (cf. A., 1922, i, 893) of oxyhæmoglobin and reduced hæmoglobin are practically constant over the physiological range of  $P_{H_2}$ , that for the former being  $\beta_{H_2} = 2.64$  and for the latter  $\beta_{H_2} = 2.45$ . The authors conclude from these values that the alkali taken up by hæmoglobin is shared between at least five univalent acid groups. The total amount of base bound by hæmoglobin at  $P_{H_2}$  values varying from 7.2 to 7.5 is given by the equation:  $B = 2.64[HbO_2](P_{H_2} - 6.585) + 2.45[Hb](P_{H_2} - 6.80)$ . E. S.

**Gas and Electrolyte Equilibria in the Blood. IV. The Effect of Oxygenation and Reduction on the Bicarbonate Content and Buffer Value of Blood.** DONALD D. VAN SLYKE, A. BAIRD HASTINGS, and JAMES M. NEILL (*J. Biol. Chem.*, 1922, 54, 507-526).—The experiments recorded in the previous paper have been extended to oxygenated and reduced horse blood (oxalated or defibrinated). Since carbonic acid and hæmoglobin are the only acids present in blood, the assumption has been made, in interpreting the results, that changes in the amount of base present as bicarbonate are accompanied by equal and opposite changes in the amount combined with hæmoglobin. The results show that each specimen of blood, when at the same degree of oxygenation, has a constant buffer value over the  $P_{H_2}$  range 7.2 to 7.5, the average values of different specimens being 25.3 for oxygenated blood and 24.4 for reduced blood (buffer values are here expressed as millimols. of base per unit change in  $P_{H_2}$ ; cf. A., 1922, i, 893). The difference between these two values is due to the loss of buffer value which occurs when oxyhæmoglobin is reduced (cf. preceding abstract), a loss which is partly compensated for by an increase in bicarbonate content. Thus, of the total buffer value, hæmoglobin was responsible for 76.0% and bicarbonate for 6.9% in oxygenated blood, the figures for reduced blood being 73.3% and 9.0%, respectively. Each additional molecule of oxygen taken up by hæmoglobin at  $P_{H_2}$  7.3 caused decreases in the bicarbonate content varying from 0.50 to 0.59 in different specimens. On the above assumption, a mol. of hæmoglobin when changed from the reduced to the oxygenated state therefore combines with an additional 0.50-0.59 equivalent of alkali. This value differs

from that obtained with solutions of crystallised hæmoglobin and is hence probably influenced by some unknown variable factor in blood. As for solutions of hæmoglobin, the amount of additional base combined with hæmoglobin in blood on oxygenation was directly proportional to the amount of oxygen combined. Over the range  $P_H$  7.2 to 7.5 a rise of  $P_H$  0.1 caused an increase of approximately 0.02 equivalent in the amount of base transferred from bicarbonate to hæmoglobin by one molecule of oxygen. E. S.

**Evaluation of Buffers of the Blood.** EDWARD A. DOISY, A. P. BRIGGS, EMILY P. EATON, and WILLIAM H. CHAMBERS (*J. Biol. Chem.*, 1922, 54, 305—329).—The authors have investigated the extent to which the various known buffer systems of the blood participate in binding carbon dioxide during the change of blood from the arterial to the venous state. In the results obtained from three specimens of human blood, from 87—95% of the carbon dioxide has been accounted for. Of the total amount taken up, 75—80% was due to the hæmoglobin, less than 1% to the inorganic phosphates, and less than 5% to the buffers contained in the separated serum. E. S.

**Measurement of the Alkalinity of the Blood.** CH. O. GULLAUMIN (*J. Pharm. Chim.*, 1923, [vii], 27, 5—23).—For the measurement of the  $P_H$  of the blood and the alkaline reserve, the methods described by Cullen (*J. Biol. Chem.*, 1922, 52, 508) with very slight modifications give accurate results with inexpensive apparatus. H. K.

**Relations Existing between Arterial and Venous Blood of the Dog with Special Reference to the Plasma Chlorides.** EDWARD A. DOISY and J. W. BECKMANN (*J. Biol. Chem.*, 1922, 54, 683—691).—Analyses were made of arterial and venous blood drawn simultaneously from dogs. The results show that the migration of hydrochloric acid from plasma to corpuscles, which is to a large extent responsible for the buffer action of blood in vitro (cf. A., 1922, i, 963), occurs also in vivo as blood passes from the arterial to the venous state. Evidence was also obtained, although the results were less consistent, that the blood respiratory coefficient has a normal value, that the additional carbon dioxide contained in venous blood is approximately equally distributed between plasma and corpuscles, and that the corpuscles occupy a larger volume in venous than in arterial blood. E. S.

**Non-protein Organic Constituents in the Blood of Marine Fish.** W. DENIS (*J. Biol. Chem.*, 1922, 54, 693—700).—Analyses previously made (A., 1914, i, 106) have been repeated using recent methods. The following are the average results, expressed in mg. per 100 c.c. of blood, for different species of elasmobranch and teleost fishes: Elasmobranch blood—non-protein nitrogen, 1000; urea nitrogen 800; amino-nitrogen 28; creatinine 6; creatine 25; uric acid 1.1. Teleost blood—non-protein nitrogen 65; urea nitrogen 9; amino-nitrogen 28; creatinine 1.0; creatine 6; uric acid 4. The blood of invertebrates was found frequently to contain

20 amino-nitrogen although considerable amounts were present  
in the muscle. E. S.

**The Neutrality of Blood.** J. MELLANBY and C. C. WOOD (*Proc. Physiol. Soc.*, 1922, lii-lii; *J. Physiol.*, 1922, 56; from *Physiol. Abstr.*, 1922, 7, 490).—Corpuscles, partly freed from carbon dioxide and suspended in 0.85% sodium chloride solution, have a slightly acid reaction. When exposed to alveolar air, these corpuscles absorb carbon dioxide and the reaction tends to neutrality. On the other hand, serum from the same blood is alkaline in reaction and on exposure to alveolar air becomes more acidic. This apparently paradoxical effect of carbon dioxide explains the approximate neutrality of the blood under varying tensions of carbon dioxide, and perhaps also the divergence which exists between the calculated reaction of the blood, based on the ratio of the free and combined carbon dioxide contained in it and that actually observed by direct experiment. W. O. K.

**Combined Uric Acid in Ox Blood.** ALICE ROHDE DAVIS, ELEANOR B. NEWTON, and STANLEY R. BENEDICT (*J. Biol. Chem.*, 1922, 54, 595—599).—The uric acid compound present in the corpuscles of ox blood (cf. A., 1915, i, 612) has been isolated. It forms square plates which do not melt under 300°, and when hydrolysed with sulphuric acid yields equimolecular quantities of uric acid and *d*-ribose. It is apparently a monobasic acid; its sodium salt has  $[\alpha]_D^{20} + 20.42^\circ$ . E. S.

**Distribution of the Combined Uric Acid in the Corpuscles of Ox Blood.** ELEANOR B. NEWTON and ALICE ROHDE DAVIS (*J. Biol. Chem.*, 1922, 54, 601—602).—The combined uric acid (cf. preceding abstract) is present entirely in the erythrocytes. E. S.

**Combined Uric Acid in Human, Horse, Sheep, Pig, Dog, and Chicken Blood.** ELEANOR B. NEWTON and ALICE ROHDE DAVIS (*J. Biol. Chem.*, 1922, 54, 603—605).—The combined uric acid compound (cf. preceding abstracts) seems to be present in the blood of all the above species but in much smaller amounts than in ox blood. E. S.

**Influence of Subcutaneous Injections of Indole and Scatole on the Nitrogenous Metabolism of the Rabbit.** FRANK P. UNDERHILL and ROBERT KAPINOW (*J. Biol. Chem.*, 1922, 54, 717—720).—Using doses of 30 mg. per kg., no influence was observed. Indole, but not scatole, apparently increased the excretion of ethereal sulphates. E. S.

**Inorganic Metabolism. I. Inter-relations between Calcium and Magnesium Metabolism.** L. JEAN BOGERT and ELIZABETH J. MCKITTRICK (*J. Biol. Chem.*, 1922, 54, 363—374).—The addition of magnesium citrate in amounts of 6 g. per day to the diet of four subjects caused an increased excretion of magnesium both in the urine and faeces. There was also an increase in each case in the total calcium excreted, and, in three out of the four

cases, in both urinary and faecal calcium. The similar addition of calcium lactate caused increase in both urinary and faecal calcium. There was probably also an increased excretion of magnesium.

E. S.

**Inorganic Metabolism. II. Effects of Acid-forming and Base-forming Diets on Calcium Metabolism.** L. JEAN BOGERT and ELIZABETH E. KIRKPATRICK (*J. Biol. Chem.*, 1922, **54**, 375—386).—Although certain irregularities occurred, the results, in the main, indicate that acid-forming diets divert calcium from the faeces to the urine and also cause an increased total excretion. Base-forming diets, on the other hand, divert calcium from the urine to the faeces and produce a diminution in the total excretion.

E. S.

**Inorganic Metabolism. III. Influence of Yeast and Butter Fat upon Calcium Assimilation.** L. JEAN BOGERT and RUTH K. TRAIL (*J. Biol. Chem.*, 1922, **54**, 387—397).—In the case of four women, the addition of either yeast or butter fat to a diet which was otherwise vitamin-free produced an increased retention of calcium. The amount of calcium excreted in the faeces was diminished.

E. S.

**Antiketogenesis. IV. The Ketogenic-Antiketogenic Balance in Man and its Significance in Diabetes.** PHILIP A. SHAFFER (*J. Biol. Chem.*, 1922, **54**, 399—441).—Further work on the ketolytic reaction in vitro (cf. A., 1921, i, 754) has shown that, under proper conditions, one molecule of dextrose accomplishes the disappearance of two molecules of acetoacetic acid when the latter is in excess. On this basis, the values previously assigned (A., 1922, i, 83) to the antiketogenic factors must be doubled. This conclusion is supported by the results obtained by Wilder and Winter (A., 1922, i, 893), but when applied to cases taken from the literature it leads to a calculated excretion of acetone substances which is considerably smaller than that actually found. The protein ketogenic factor has therefore been arbitrarily increased by 50%. With this modification, moderate agreement between the calculated and actual values has been obtained. In cases of severe ketosis (where the acetoacetic acid is in excess), each molecule of dextrose appears, without doubt, to be equivalent ketolytic substance for two molecules of keto-acid. At the threshold of ketosis, however, the dextrose molecule may have a lower value owing to oxidation taking place without its coming into contact with the keto-acid. The author discusses the bearing of these results on the dietetic problem of diabetes.

E. S.

**Colorimetric Researches on Tryptophan. VII. The Tryptophan Requirements of Growing Rats (a Contribution to the Question of Cyclopoiesis).** OTTO FÜRTH and FRIEZ LIEBEN (*Biochem. Z.*, 1922, **132**, 325—341).—Only a small fraction (3—8%) of the tryptophan consumed by rats is retained in the

body, the rest being destroyed. The minimal tryptophan requirement for rats per kg. of body weight is greater than for man.

W. O. K.

**Physical Chemistry of Foodstuffs. Investigation of Acid-taste.** THEODOR PAUL (*Z. Elektrochem.*, 1922, 28, 435—446).—By the employment of the methods of psychophysics, and the introduction of a new terminology, the measurement of acid-taste has been placed on a quantitative basis. Molecular acidity is defined as the number of mols. of hydrochloric acid, dissolved in a fixed volume of water, which tastes as acid as one mol. of the acid substance dissolved in the same volume of water. The molecular acidity is determined, not only by the hydrogen-ion concentration, but also by the capacity of the solute to yield its reserve of hydrogen-ions to the tongue, and, to some extent, by the nature of the anion and the vapour pressure of the acid. The acids investigated have been arranged in a series of increasing molecular acidities, thus: carbonic acid, potassium hydrogen tartrate, acetic acid, lactic acid,  $\alpha$ -acetoxypropionic acid, hydrochloric acid, and tartaric acid. In this series, carbonic acid possesses the weakest, and tartaric acid the strongest acid taste. This order is not in agreement with the dissociation constants of these acids. For example, the two acids,  $\alpha$ -acetoxypropionic and tartaric acids, although possessing very similar dissociation constants, show very different molecular acidities. The molecular acidity decreases slowly with increase in concentration. The curves obtained by plotting acid taste against concentration show several points of resemblance with the "sweetness" curves of "saccharin" and dulcin. The two properties, acid-taste and sweetness, behave in an analogous manner with increase in concentration, and this suggests that similar relationships may exist between these and the salt and bitter qualities of substances.

W. E. G.

**The Course of Oxidative Processes [in the Cell].** HEINRICH VIELAND (*Ber.*, 1922, 55, [B], 3639—3648).—A lecture delivered at the centenary of the *Versammlung Deutscher Naturforscher und Ärzte*.

H. W.

**Glutathione. II. A Thermostable Oxidation-Reduction System.** F. GOWLAND HOPKINS and M. DIXON (*J. Biol. Chem.*, 1922, 54, 527—563).—A continuation of the investigation of the recently discovered glutathione (A., 1921, i, 635) has shown that, in its functions in the cell, this dipeptide is mainly associated with insoluble, thermostable agents which act as hydrogen donors and form with it the thermostable reducing system of the tissues. Thus, tissue which has been extracted with water, treated repeatedly with boiling water or alternatively heated for three hours at 100°, dehydrated with alcohol, and finally dried in a vacuum, all the operations being performed anaerobically, when ground and suspended in a phosphate buffer mixture ( $P_H$  7—8) containing oxidised glutathione is able rapidly to reduce methylene-blue, that portion of its reducing power which depends on the presence of the di-

peptide being practically unaffected by this treatment. The thermostable agents are, however, sensitive to oxidation (for example, by hydrogen peroxide) and are even slowly destroyed by molecular oxygen. The latter effect is enormously accelerated by the presence of glutathione. When suspensions of muscular tissue, prepared as above, are aerated in the presence of the dipeptide oxygen is absorbed to the extent of 400 c.mm. for every gram of dry material used. At the same time carbon dioxide is given off, the "respiratory quotient" of the process being about unity at first and falling off considerably during the later stages. These results suggest that a thermostable mechanism for oxidations and reductions coexists with the specialised enzymic mechanism in living tissue.

E. S.

**Proportion of Sulphur in the Skin of Children Aged Less than One Year.** E. LABORDE (*Bull. Soc. Chim. biol.*, 1922, 4, 584—586).—In the skin of three children approximately 0.2% of sulphur was found. In the healthy skin of another who had died from poisoning by sulphuric acid, there was 0.15%, whilst the burned areas of the skin contained 0.37%.

W. O. K.

**Chemistry of the Liver.** UBALDO SAMMARTINO (*Biochem. Z.*, 1922, 132, 343—351).—An analysis of the fats in horse liver shows the presence of kephalin, lecithin, myristic acid, butyric acid, and other fatty acids, and certain glycerol and cholesterol esters.

W. O. K.

**The Proteolytic Enzymes of the Spleen.** S. G. HEDIN (*J. Biol. Chem.*, 1922, 54, 177—202).—At least three enzymes, namely,  $\alpha$ -protease,  $\beta$ -protease, and crepsin, are present in the spleen of the ox (cf. A., 1904, ii, 58; Morse, A., 1917, i, 606; Dornby, A., 1918, i, 464). A partial separation of these has been effected by extracting the minced spleen successively with dilute acetic acid, casein, and 5% sodium chloride. The acetic acid extract contains all three enzymes; the casein extract contains mainly  $\beta$ -protease and erepsin; whilst a solution in sodium hydroxide of the globulin obtained from the sodium chloride extract contains mainly  $\alpha$ -protease. If the spleen is kept for any length of time in alkaline solution or at an acidity less than  $P_H$  5.2, the enzymes show a loss of activity which cannot be revived by acids.  $\alpha$ -Protease, which acts in alkaline solution, converts proteins into peptones more rapidly than peptones into amino-acids; its action is inhibited by serum-albumin (cf. also Bradley, A., 1922, i, 896).

E. S.

**The Catalytic Destruction of Carnosine in Vitro.** WINIFRED MARY CLIFFORD (*Biochem. J.*, 1922, 16, 792—799).—A catalyst is described which is capable of destroying carnosine in muscle extract. It is present in ox, rat, and cod muscle, but is absent in the muscle of invertebrates such as the oyster and the lobster. It is also present in the liver of the rat and of the ox. The kidney of the rat, ox, or sheep does not contain it. The curve of action of this catalyst is unlike any enzyme curve. The possible mechanism of

its action is discussed. It is also suggested that carnosine may be an intermediate product of metabolism. S. S. Z.

**Excretion of Acid and Ammonia.** ROGER S. HUBBARD and SAMUEL A. MUNFORD (*J. Biol. Chem.*, 1922, **54**, 465—479).—From a statistical analysis of the results of a series of analyses of human urine the authors conclude that the excretion of ammonia varies with the volume and the reaction of the urine but is not directly affected by the amount of acid excreted. The relation between the reaction of the urine and the excretion of ammonia is concerned rather with the concentration of the ammonia than with the actual amount excreted. The latter fact is interpreted as supporting the theory (Nash and Benedict, A., 1922, i, 191, 483) that the kidney is the seat of formation of ammonia. E. S.

**The Influence of Fat and Carbohydrate on the Nitrogen Distribution in the Urine.** EDWARD PROVAN CATHCART (*Biochem. J.*, 1922, **16**, 747—753).—The output of total nitrogen, urea, and ammonia rises on a fat diet and falls on the addition of carbohydrate. The output of uric acid is low on the fat diet and increases on the addition of carbohydrate whilst the output of total creatinine is but little affected by the change of diet. Small amounts of creatine are excreted on a carbohydrate-free diet. The output of undetermined nitrogen is greater on diets containing carbohydrate than those from which carbohydrate is absent. S. S. Z.

**Constancy of the Creatine-Creatinine Excretion in Children on a High Protein Diet.** VICTOR JOHN HARDING and OLIVER HENRY GAEBLER (*J. Biol. Chem.*, 1922, **54**, 579—587).—The same amount of total creatine (creatine+creatinine) is excreted by normal children of the same age when under the same environment. The amount excreted per kg. of body weight ("total creatine coefficient") is constant for children of all ages and is of the same magnitude as the creatinine coefficient of an adult man. E. S.

**Elimination of Cholesterol in Urine.** WILHELM GRUNKE (*Biochem. Z.*, 1922, **132**, 543—555).—Cholesterol occurs in normal urine only in traces. In one case of icterus out of nine, 10.1 mg. per day was found, and in one case of diabetes out of five, 12.9 mg.; in other cases there was no more than a normal amount. W. O. K.

**Comparative Toxicity of Ammonium Salts.** FRANK P. UNDERHILL and ROBERT KAPSINOW (*J. Biol. Chem.*, 1922, **54**, 451—457).—From experiments on rats it is concluded that, in general, the toxicity of ammonium salts is directly proportional to their content of ammonia. E. S.

**Pharmacological Analogues of  $\alpha$ -2-Aminotetrahydronaphthalene.** JULIUS VON BRAUN, HEINRICH GRUBER, and GEORG KIRSCHBAUM (*Ber.*, 1922, **55**, [B], 3664—3674).—See this vol., i, 107.

## Chemistry of Vegetable Physiology and Agriculture

**Some Microbiological Consequences of the Oxidising Properties of Thorium-X.** P. LEMAY and L. JALOUSTRE (*Compt. rend.*, 1922, 175, 1053—1054; cf. A., 1922, ii, 13, 186).—In order to ascertain whether radioactive elements function as oxidation catalysts with regard to the activities of micro-organisms, cultures of anaërobic and aërobic organisms were submitted to the action of thorium-X. In the case of the anaërobic species (*Bacillus butyricus*) the radioactive material exercised an inhibiting effect on development, the number of bacteria being about one-twentieth and the gas evolved about one-third of that in the control experiment, whilst the action of the catalyst on the aërobic species (*B. lacticus*) appeared to be of a favourable nature. H. J. E.

**Influence of the Culture Conditions on the Liquefaction of Gelatin and on the Production of Indole by Bacteria.** OTTO ARNBECK (*Biochem. Z.*, 1922, 132, 457—479).—The production of indole and the liquefaction of gelatin by bacteria are inhibited by nitrogen-free foodstuffs such as glucose. Free ammonia, on the other hand, assists the liquefaction. W. O. K.

**Ultra-violet Absorption Spectra of some Vitaminic Extracts.** HORACIO DAMIANOVICH (*Anal. Asoc. Quím. Argentina*, 1922, 10, 209—214).—Yeast extracts containing vitamin-B show characteristic absorption spectra in the ultra-violet with general absorption in the extreme portion of the spectrum, and a band between 2478 and 2660 Å. which appears to be due to a pyrimidine or purine group. The absorption spectra of the oils from white and yellow maize, respectively, were also studied and a difference observed corresponding with the presence of vitamin-A in yellow maize oil and its absence from white maize oil. It is uncertain whether there is a causal connexion between presence of pigment and presence of vitamin-A in the yellow maize oil. Photospectrographs of the liquids examined are appended. G. W. R.

**Synthesis of Water-soluble [Vitamin]-B by Yeast Grown in Solutions of Purified Nutrients.** MARGARET B. McDONALD (*J. Biol. Chem.*, 1922, 54, 243—248).—Using five different varieties of yeast, the author confirms the conclusion of Nelson, Fulmer, and Cessna (A., 1921, i, 386) that this organism is able to synthesise vitamin-B. E. S.

**Vitamin-D.** TREVOR BRABY HEATON (*Biochem. J.*, 1922, 16, 800—808).—The activating substance of minimal concentrations of yeast (called by Wildiers "bios" and by Funk vitamin-D) is not identical with vitamin-B. Organs of pigeons rendered polynuritic contain it in the same amount as those of normal pigeons. Its distribution differs from that of antineuric vitamin. Rats subsisting on a diet deficient in the water-soluble vitamin incur also the deficiency of this activating substance. S. S. Z.

**Influence of Amines on Fermentation.** JULIUS ORIENT (*Biochem. Z.*, 1922, 132, 352—361).—The various amines used show in general a retarding effect on fermentation by yeast when applied in a concentration of 4·8%. This effect, however, changes into one of acceleration if the concentration of the amine be either higher or lower, except in the cases of methylamine and betaine which inhibit the fermentation even in low concentrations.

W. O. K.

**Fermentation of Sugar in Presence of Sodium Sulphite following Neuberg and Reinfurth. Equivalence between Aldehyde and Glycerol.** HEINRICH GEHLE (*Biochem. Z.*, 1922, 132, 566—588).—In the fermentation of sucrose by yeast in the presence of sodium sulphite there is in general rather more than one equivalent of glycerol formed for one equivalent of acetaldehyde. This is particularly the case with small amounts of sulphite, and a short fermentation time. As increased proportions of sulphite are used, the rate of increase in the yields of glycerol and of acetaldehyde gradually decreases until the maximum yield obtained using 60% of sulphite calculated on the sugar. With increasing percentage of sulphite, the rate of evolution of carbon dioxide is decreased.

W. O. K.

**Equivalence in the Production of Acetaldehyde and Glycerol at the Second Form of Fermentation.** C. NEUBERG, J. HIRSCH, and E. REINFURTH (*Biochem. Z.*, 1922, 132, 589—596).—Gehle's results (preceding abstract) are vitiated by a systematic error in the estimation of the acetaldehyde. If this be estimated gravimetrically by the "dimedon" method (A., 1920, i, 914), precise equivalence between glycerol and acetaldehyde is found.

W. O. K.

**The Chemistry of Fermentative Phenomena.** CARL NEUBERG (*Ber.*, 1922, 55, [B], 3624—3658).—A lecture delivered at the centenary of the Versammlung Deutscher Naturforscher und Aerzte.

H. W.

**The Presence of Urease and Urea in Fungi.** A. GORIS and P. COSTY (*Compt. rend.*, 1922, 175, 998—999; cf. A., 1922, i, 1220).—The distribution of urease in the pileus, stipe, and hymenium of twelve species of fungi was investigated. In all cases the hymenium contains the greatest proportion of the ferment. A brief account of the method of extraction and estimation of the urease is given.

H. J. E.

**The Action of the Nitrogen of Hexamethylenetetramine on Plant Growth.** E. BLANCH, W. GEHMANN, and F. GIESECKE (*J. Landw.*, 1922, 70, 221—251).—Pot experiments are described, which show that hexamethylenetetramine is as effective a fertiliser as ammonium sulphate. The soil bacteria decompose the substance into ammonia, which is nitrified in the usual way. The presence of hexamethylenetetramine in liquid farmyard manure, preserved by the addition of formaldehyde, brings no unfavourable consequences.

A. G. P.

**The Effect of the Kations of Salts on the Destruction and Synthesis of Starch in Plants.** W. S. ILJIN (*Biochem. Z.*, 1922, 132, 494—510).—The rate of disappearance of starch from plant cells immersed in a solution of a salt is influenced by the kation of the salt. Univalent kations and also barium and glucinum effect the solution of the starch and at the same time cause an increase of the osmotic pressure in the cell, whilst magnesium, calcium, and strontium are inactive. If, on the other hand, the cells be immersed in a solution of maltose the synthesis of starch is inhibited by the presence of barium, caesium, lithium, sodium, calcium, potassium, rubidium, magnesium, and strontium in order of decreasing activity.

W. O. K.

**Synthesis and Hydrolysis of Starch under the Influence of Anions in Plants.** W. S. ILJIN (*Biochem. Z.*, 1922, 132, 511—525; cf. preceding abstract).—Similar results are obtained with anions, the organic anions being particularly active in raising the osmotic pressure and influencing the synthesis and hydrolysis of starch.

W. O. K.

**Physiological Protection in Plants against the Harmful Action of Salts.** W. S. ILJIN (*Biochem. Z.*, 1922, 132, 526—542; cf. preceding abstracts).—The salt effects described in the preceding two abstracts would be harmful to plants, but it appears that certain ions act antagonistically to each other. Calcium, for instance, may inhibit the effect of sodium. In this way, the existence of halophytes may be understood.

W. O. K.

**Pigments of the Mendelian Colour Types in Maize: iso-Quercitrin from Brown-husked Maize.** CHARLES E. SANDO and H. H. BARTLETT (*J. Biol. Chem.*, 1922, 54, 629—645).—iso-Quercitrin has been isolated from the husks of a brown-husked maize. It forms primrose-yellow, needle-like plates, m. p. 220—222.5°, and is probably identical with the ragweed glucoside obtained by Heyl (A., 1919, i, 615). Aqueous solutions of iso-quercitrin give an olive-green coloration with ferric chloride, a yellow precipitate with lead acetate, and a rose-red colour on reduction with magnesium and hydrochloric acid. The yellow colour of the substance is intensified by sodium carbonate and dilute ammonia. The spectral transmission curves of both iso-quercitrin and quercetin have been determined.

E. S.

**Biological Adsorption from Solutions of Metallic Salts.** FRIEDRICH PICHLER and ARTUR WÖBER (*Biochem. Z.*, 1922, 132, 420—438).—An investigation of the adsorption particularly of copper and also of mercury and cerium from solutions of their salts, by the spores of maize rust (?) (*Maisbrandsporen*). In general there is a connexion between the degree of adsorption and the toxicity of the ion.

W. O. K.

## Organic Chemistry.

**New System for the Linear Representation of the Structure of all Organic Compounds.** T. SHERLOCK WHEELER (*Chem. News*, 1923, 126, 33—35, 49—50, 66—67).—A system designed to enable the structure of all organic compounds to be represented linearly by a simple arrangement of letters and figures, from which, with the aid of a few rules, the graphical formula could be deduced easily. The original must be consulted, as the paper does not end itself to abstraction.

**The Solubility of Methane in Water and Organic Solvents under Pressure.** F. FISCHER and C. ZERBE (*Brennstoff-Chem.*, 1922, iv, 17—19).—The solubility of mine gases of the composition methane 79.4%, carbon dioxide 0.7%, oxygen 2.8%, and nitrogen 17.1% in a large number of solvents under a pressure of about 10 atm., and also the composition of the gases evolved from the solvent were determined. The latter in most cases differed little from that of the original mixture, so that the figures obtained may be taken as approximately true for pure methane. The figure for the solubility in water (0.09 c.c. per g. for 1 atm.) is, however, so high owing to the higher solubility of carbon dioxide. The highest figure obtained is 1.34 for light petroleum (b. p. below 65°) others include: for ethyl alcohol 0.60, for chloroform 0.32, for niline 0.16. If the product of these solubility figures and the surface tension of the solvent are calculated, a series of figures which approximate to a constant is obtained as previously shown by Christoff for carbon monoxide. Water, nitrobenzene, aniline, and chloroform are exceptions. Both surface tension and solubility, however, decrease with a rise in temperature, and it is questionable whether a fair comparison is obtained at a uniform temperature (20°) between liquids of widely differing b. p. C. I.

**The Constituents of the Fraction of a Borneo Petroleum which Distills between 37° and 81°.** G. CHAVANNE (*Bull. Soc. Chim. Belg.*, 1922, 31, 331—364).—An examination of the petrol showed that all the possible isomerides of hexane are present, as are all the hydrocarbons derived from cyclopentane and cyclohexane the boiling points of which are included in the fraction investigated. With the exception of ethylcyclobutane, all the cyclic compounds present are derived from five- or six-membered rings. Of the hexanes present, normal hexane is the most abundant, followed by isohexane and  $\gamma$ -methylpentane, whilst  $\beta\beta$ -dimethylbutane and  $\beta\gamma$ -dimethylbutane are present in much smaller proportion. The saturated cyclic hydrocarbons present in quantity are cyclohexane and methylcyclopentane. A number of physical constants are given which differ slightly, if at all, from those in the literature, and the author states that the critical

temperature of solution in aniline (cf. Chavanne and Simon, A., 1919, ii, 267, 432, 433) and the density are important factors in the experimental study of complex mixtures of hydrocarbons (cf. Chavanne and Simon, A., 1919, i, 380). H. J. E.

**The Mechanism of Thermal Decomposition of the Pentanes**  
G. CALINGAERT (*J. Amer. Chem. Soc.*, 1923, 45, 130—135).—

When pentane vapour is passed through a tube at 600°, it is decomposed, giving hydrogen and a mixture of hydrocarbons. Under the experimental conditions, about 30% of the pentane is decomposed and 44% of the product consists of unsaturated hydrocarbons. The product contains hydrogen 5%, methane 12%, ethane 26%, propane 10%, pentane 4%, ethylene 10%, propylene 24%, butylene 3%, and 6% of a  $C_4H_6$  hydrocarbon. These results correspond with a rupture of the pentane molecule at the central carbon atom, giving an ethyl and a propyl group, one of which is then saturated at the expense of the other, which becomes unsaturated, the change going mainly in the direction of forming ethane and propylene. Under similar conditions, isopentane is also decomposed and an analysis of the products shows that in this case the molecule breaks on one side or the other of the tertiary carbon atom. This results in a methyl and an isobutyl group which give methane and  $\Delta^1$ - or  $\Delta^2$ -butylene. A second reaction gives an ethyl and an isopropyl group and ethane results, but never propane. There is also another reaction which occurs to a small extent and results in the formation of amylene, and, finally, a part of the amylene and butylene give, by a secondary reaction, butadiene and pentadiene. W. G.

**Constitution of Squalene.** RIKO MAJIMA and BENNOSUKÉ KUBOTA (*Japan. J. Chem.*, 1922, i, 19—33).—An English translation of the paper previously published in Japanese (this vol., i, 1). K. K.

**Preparation of Methyl Bromide.** ARTUR BYGDÉN (*J. pr. Chem.*, 1922, [ii], 104, 285—288).—Steinkopf and Schwen (A., 1921, i, 841) have obtained a 77% yield of methyl bromide, calculated on the bromine taken, if the reagents are employed in the ratio of 1 atom Br+0.5 atom P+2.5 mol. MeOH. It is now shown (cf. A., 1911, i, 43; also Holt, T., 1916, 109, 1) that a 97.3% yield may be obtained by using the following molecular proportions:  $1KBr:3H_2SO_4:2MeOH$ , the acid being diluted with one-third its weight of water previously to the addition of the other reagents. The most economical preparation, considering the cost of all the materials, is, however, effected by the use of  $1KBr:3H_2SO_4:1.25MeOH$ , the yield being then 95.9%. W. S. N.

**The Spontaneous Decomposition of Unsaturated Aliphatic Iodochlorides.** LLOYD B. HOWELL (*J. Amer. Chem. Soc.*, 1923, 45, 182—187; cf. Noyes, A., 1920, i, 469).—When  $\beta$ -chloroethylenic iodochloride decomposes spontaneously the products are iodine

monochloride, trichloroiodoethane,  $\alpha\beta\beta$ -tetrachloroethane, and  $\alpha$ -iodochloroiodoethane, and of these the first two are formed in much larger amounts than the last two. Under similar conditions,  $\beta$ -dichloro- $\beta$ -iodoethylene iodochloride gives no saturated compound except hexachloroethane. The principal products in this case are iodine monochloride and dichlorodi-iodoethylene, together with some  $\alpha$ -chloro- $\alpha\beta\beta$ -tri-iodoethylene and some trichloroiodoethylene. The changes consist in several rearrangements involving the splitting off of chlorine and iodine monochloride from the iodochloride group, the addition of one molecule of iodine monochloride or of chlorine to the unsaturated residues, and the replacement of iodine by chlorine or vice versa. If the carbon atoms of the double union in an unsaturated aliphatic  $\alpha$ -iodochloride hold hydrogen atoms, the products of its decomposition are saturated halogen derivatives, but if they hold only halogen atoms, the decomposition leads to unsaturated products. Compounds described are:  $\alpha\beta\beta$ -trichloro- $\alpha$ -iodoethane, b. p.  $101-102^\circ/31-32$  mm.,  $d_4^{25}$  2.266,  $n_D^{25}$  1.5834; (1)  $\alpha\alpha$ -dichloro- $\beta$ -iodoethane, b. p.  $146-148^\circ/28$  mm.,  $d_4^{25}$  2.861;  $\alpha\beta$ -dichloro- $\alpha\beta$ -di-iodoethylene, b. p.  $243.4^\circ$ , m. p.  $2.5-3.0^\circ$ ,  $d_4^{25}$  2.934; and  $\alpha$ -chloro- $\alpha\beta\beta$ -tri-iodoethylene.

W. G.

**Synthesis by Means of Magnesium Allyl Halides.** SAMUEL JOFFEY (*Rec. trav. chim.*, 1922, 41, 652-654).—A repetition of Jaworsky's preparation of allyldimethylcarbinol (A., 1909, i, 151) showed that dimethylallylcarbinyl allyl ether,  $C_3H_5 \cdot CMe_2 \cdot O \cdot C_3H_5$ , is obtained as a by-product, the yield being about 20%, calculated on the basis of the allyl chloride used. It is a pale yellow, mobile oil, b. p.  $190-193^\circ$ ,  $d_4^{25}$  0.8765,  $d_4^{20}$  0.8754,  $n_D^{25}$  1.4750. Dimethylallylcarbinol has m. p.  $-73^\circ$ ,  $d_4^{25}$  0.83553,  $d_4^{20}$  0.83452,  $n_D^{25}$  1.430. The acetate, obtained in 40% yield by modifying Houben's method (A., 1906, i, 520), has m. p.  $-94.5^\circ$ , b. p.  $46-48^\circ/21$  mm., or  $136-138^\circ$ /atmospheric pressure (decomp.),  $d_4^{25}$  0.88797,  $d_4^{20}$  0.88720,  $n_D^{25}$  1.4230. Neither of these substances reacted with solutions of perbenzoic acid.

H. J. E.

**The Oxidation of Propylene Glycol with Potassium Permanganate.** WILLIAM LLOYD EVANS (*J. Amer. Chem. Soc.*, 1923, 45, 171-176; cf. A., 1912, i, 743).—A study of the oxidation of propylene glycol by potassium permanganate at  $50^\circ$  and  $75^\circ$  in the presence of various concentrations of alkali. In neutral solutions, the products are acetic acid and carbon dioxide, but above certain minimum concentrations of alkali, oxalic acid is also an oxidation product. Rise in temperature causes an increase in the production of carbon dioxide and a decrease in the acetic acid. Lactic and pyruvic acids are probably two of the intermediate products, the lactic acid arising either from the oxidation of lactaldehyde or from the rearrangement of pyruvaldehyde in the presence of alkalis. The acetic acid is probably obtained either from the oxidation of acetaldehyde, present as a dissociation product, or from the oxidation of pyruvic acid. The oxalic acid is probably formed ( $\alpha$ ) by the oxidation of glycollic acid obtained

h 2

by the oxidation of vinyl alcohol, or (b) by the oxidation of glyoxylic acid, formed from pyruvic acid. Carbon dioxide may arise from the oxidation of formaldehyde, pyruvic acid, or glyoxylic acid. The alkali functions (a) by neutralising the acids formed, (b) by increasing the enolisation of acetaldehyde and pyruvic acid, (c) by causing the rearrangement of pyruvaldehyde to lactic acid. As the concentration of the alkali increases, the dissociation of the three-carbon atom compounds into two other compounds is suppressed in that direction, owing to the increased activity of the alcohol groups in propylene glycol, due to the lower point of dissociation of the alkyl oxides formed in comparison with that of the alcohol itself.

W. G.

**The Formation of Geometrical Isomerides by the Reduction of Acetylene Derivatives.** JUL. SALKIND (*Ber.*, 1923, 56, [B], 187—192).—It has been shown previously (A., 1907, i, 22) that  $\beta$ -dihydroxy- $\beta$ -dimethyl- $\Delta^7$ -hexinene,  $\text{OH}\cdot\text{CM}_2\cdot\text{C}:\text{C}\cdot\text{CM}_2\cdot\text{OH}$ , smoothly adds two atomic proportions of hydrogen in the presence of colloidal palladium and passes thereby into  $\beta$ -dihydroxy- $\beta$ -dimethyl- $\Delta^7$ -hexene,  $\text{OH}\cdot\text{CM}_2\cdot\text{CH}:\text{CH}\cdot\text{CM}_2\cdot\text{OH}$ , slender needles, m. p.  $76\cdot5$ — $77^\circ$  ( $\alpha$ -form). It has now been found possible to isolate the isomeric  $\beta$ -form, monoclinic prisms, m. p.  $69$ — $69\cdot5^\circ$ , the relationship of which to the  $\alpha$ -variety is established by the observation that either compound is smoothly hydrogenated in the presence of spongy platinum to tetramethylbutanediol. The  $\alpha$ - and  $\beta$ -forms are soluble to the extent of 0.55 and 5.14 parts in 100 parts of light petroleum ( $d$  0.64—0.66) at  $16^\circ$ . Either variety is transformed by bromine in the presence of carbon tetrachloride, carbon disulphide, or anhydrous ether into a mixture of the solid dibromide,  $\text{C}_8\text{H}_{16}\text{O}_2\text{Br}_2$ , long, thin prisms, m. p.  $98\cdot5$ — $99^\circ$ , and a liquid dibromide which could not be completely purified (the relative proportions of the solid and liquid products differ according to the isomeride used).

The author has endeavoured to elucidate the configuration of the glycols by a study of their conversion into the  $\gamma$ -oxide,  $\text{CH}\cdot\text{CM}_2\cdot\text{CH}\cdot\text{CM}_2\cdot\text{O}$  (a liquid, b. p.  $102$ — $102\cdot5^\circ/755$  mm.,  $d_4^{20}$  0.8226,  $n_D^{20}$  1.4093,  $n_D^{25}$  1.40926), which should be obtainable solely from the maleinoid form. Under the action of boiling sulphuric acid (15%), of potassium hydrogen sulphate at  $160^\circ$ , or of a trace of iodine, the oxide is, however, produced in good yield from either glycol, so that interconversion appears to take place under these conditions. Since, however, it is found that the  $\alpha$ -isomeride loses water much more readily than the  $\beta$ -form when heated under similar conditions with a little iodine, it is considered to be maleinoid in structure, whereas the fumaroid configuration is assigned to the  $\beta$ -form.

The relative proportion of the  $\alpha$ - and  $\beta$ -glycols obtained by hydrogenation of the acetylenic compound appears to depend on the rapidity of the action; the production of the  $\alpha$ -variety is favoured by the rapidity of the change.

H. W.

**The Cyclic Condensation Products of Acetone with 1:3-Diols.** J. BÖESEKEN [with G. SCHAEFER and P. HERMANS] (*Rec. trav. chim.*, 1922, **41**, 722—723; cf. Böeseken and van Loon, A., 1920, i, 837; Mannich and Brose, A., 1922, i, 1118).—Two condensation products of erythritol with acetone were prepared. *Acetone-erythritol* [erythritol isopropylidene ether] has m. p. 135° and is only slightly soluble in benzene. *Diacetone-erythritol* [erythritol diisopropylidene diether], m. p. 116°, is soluble in benzene. The solubility difference affords a means of separating the substances from each other. H. J. E.

**A New Preparation of Monochloroacetic Acid.** L. J. SIMON and G. CHAVANNE (*Compt. rend.*, 1923, **176**, 309—311).—Monochloroacetic acid may readily be prepared with a yield of 90% by heating trichloroethylene with 90—93% sulphuric acid at 160—180°. The concentration of the acid and the temperature are regulated so as to give the best yield and the greatest reaction velocity. Part of the chloroacetic acid passes over with the hydrochloric acid and unchanged trichloroethylene and a certain amount remains dissolved in the sulphuric acid. The latter may be recovered by distillation under reduced pressure or by diluting the acid and extracting it with ether. Its presence dissolved in the sulphuric acid does not prevent the further use of the acid as a hydrating agent after the addition of the necessary amount of water to replace that used in the first hydration. W. G.

**Hydroxystearic Acid and some of its Derivatives.** L. GUY RADCLIFFE and W. GIBSON (*J. Soc. Dyers and Col.*, 1923, **39**, 4—10).— $\alpha$ -Hydroxystearic acid prepared by the action of sulphuric acid on oleic acid (*ibid.*, 1920, **36**, 65) and purified by repeated crystallisation from alcohol, melted sharply at 85°. The acid was further characterised by the preparation of the following derivatives: *Methyl hydroxystearate*, small, white flakes, m. p. 46°; *ethyl hydroxystearate*, white flakes, m. p. 48.5°; *acetoxystearic acid*, a white powder, m. p. 31—32°; and *ethyl benzoxystearate*, a yellow oil. As an attempt to introduce the  $-\text{NO}_2$  group into the stearic acid molecule,  $\alpha$ -bromostearic acid was prepared by Volhard's method. It is a white substance, m. p. 58°, and gives with silver nitrate, in alcoholic solution, a product free from nitrogen which seemed to be a mixture of  $\alpha$ -hydroxy- and  $\alpha$ -ethoxy-stearic acids. By the direct action of fuming nitric acid in acetic acid solution on the original  $\alpha$ -hydroxystearic acid, three substances were obtained, a greenish-yellow, crystalline compound, m. p. 83—83.5°, a yellow oil, and a white solid, m. p. 100—120°. Only the first of these was further investigated. It was free from nitrogen, and had a molecular formula approximating to  $\text{C}_{18}\text{H}_{34}\text{O}_4$ . No confirmation of this could, however, be obtained by a molecular-weight determination. Titration with alcoholic potassium hydroxide in the cold and the analysis of the silver salt gave values of 291—293, but on warming with the alkali a further half molecule was neutralised, suggesting a lactonic structure. Still no confirmation

of this was forthcoming, neither was it in accord with the number of oxygen atoms found by the combustion. G. F. M.

**$\alpha\beta$ -Dihydroxynonoic Acid.** WALTER KROHS (*Ber. Deut. pharm. Ges.*, 1922, 32, 336—338; cf. Thoms and Deckert, A., 1921, i, 219; Reinger, A., 1922, i, 623).— $\alpha\beta$ -Dihydroxynonoic acid,  $\text{CH}_3\text{Me}[\text{CH}_2]_4\text{CH}(\text{OH})\text{CH}(\text{OH})\text{CO}_2\text{H}$ , was obtained by the action of 2% potassium permanganate on the corresponding nonenoic acid (Harding and Weizmann, T., 1910, 97, 299) and has m. p.  $123^\circ$  (sinters at  $119^\circ$ ). Dehydrating agents, such as 60% sulphuric acid, do not convert it into an unsaturated substance, and with 60% sulphuric acid and 40% acetic acid a *monoacetyl* compound is formed. It is considered that the stability of the hydroxyl group to dehydrating agents is due to the proximity of the carboxyl group. The acid was resolved into its optical antipodes by means of cinchonine. The *l*-acid has  $[\alpha]_D^{20} -17.44^\circ$ ; the *dextro*-acid was not obtained quite pure. On further oxidation the acid easily decomposes, but a well characterised *dinitrate*,

$\text{CH}_3\text{Me}[\text{CH}_2]_4\text{CH}(\text{O}\cdot\text{NO}_2)\text{CH}(\text{O}\cdot\text{NO}_2)\text{CO}_2\text{H}$ , and  $\alpha\beta$ -diketononoic acid,  $\text{CH}_3\text{Me}[\text{CH}_2]_4\text{CO}\cdot\text{CO}\cdot\text{CO}_2\text{H}$ , were obtained. The latter has m. p.  $95-96^\circ$ , and its *dihydrazone*, and *disemicarbazide*, m. p.  $160^\circ$ , were prepared. P. M.

**Crystalline Structure and Properties of Tartaric Acid.** W. T. ASTBURY (*Proc. Roy. Soc.*, 1923, [A], 102, 506—528).—By X-ray analysis, employing a Coolidge bulb with molybdenum anticathode, the unit cell in the crystal structure of active tartaric acid has been shown to be monoclinic, to contain two molecules, and to have the following dimensions:  $a = 7.693 \text{ \AA}$ ,  $b = 6.037 \text{ \AA}$ , and  $c = 6.195 \text{ \AA}$ . Molecules at the corners of the cell point in one direction, whilst those lying along the central line of the cell parallel to the  $a$  axis point in a diametrically opposite direction. Intensity measurements of the reflections from various planes in the crystal enable the manner in which the unit cell is incorporated in the crystal structure to be ascertained, and hence the structure itself to be determined. This shows only one plane of perfect cleavage, viz., the plane about which lie the junctions of the hydroxyl groups, i.e., the plane (100). The junctions in the  $\text{—OH—}$  linkings are of a different type from the junctions between the hydrogens of the hydroxyl groups. In the main, the ascertained crystal structure is in accordance with known chemical and physical facts. The theory of stereoisomerism of Le Bel and van't Hoff is in its essentials confirmed, and the link between crystallographic enantiomorphs and the chemical stereoisomerides revealed. The rotatory properties of the acid are discussed with reference to the symmetry of the crystal and the spiral arrangement within the molecule, and it is shown that the assumption by Lowry of the existence of dynamic isomerides within the structure to explain these properties is unnecessary, the crystal structure itself affording a simple explanation of all the facts. Thus the fundamental crystal cell is constructed of molecules exhibiting

two spiral arrangements, one associated with the four carbon atoms forming the nucleus of each molecule, and one, oppositely directed, associated with the four hydroxyl groups. In these spiral formations are located the two opposing rotatory systems adequate to explain the anomalous rotatory properties of the acid and some of its derivatives. Most probably the dextro-rotatory property of ordinary tartaric acid is associated with the carbon nucleus of the molecule. It is shown to be impossible by the diffraction of X-rays to discriminate between the dextro- and levo-forms of an optically active substance. J. S. G. T.

**Some Complex Organic Compounds of Bismuth.** E. MOLES and R. PORTILLO (*Anal. Fis. Quím.*, 1922, 20, 571—576).—Preliminary data are given on the preparation and properties of bismuthotartaric acid, bismutholactic acid, and bismuthocitric acid. G. W. R.

**A Synthesis of Derivatives of Muconic Acid.** ERICH BENARY and RUDOLF SCHINKOPF (*Ber.*, 1923, 56, [B], 354—362).—The synthesis depends on the action of  $\alpha\beta$ -dichloroethyl ether,  $\text{CH}_3\text{CH}(\text{CHCl})\text{OEt}$ , on ethyl sodiomalonate.

$\alpha\beta$ -Dichloroethyl ether is added gradually to a suspension of ethyl sodiomalonate in boiling ether; after removal of a fraction containing chloroacetaldehyde, chloroacetal, unchanged dichloroethyl ether, and malonic ester, ethyl  $\Delta^4$ -butene- $\alpha\alpha\delta\delta$ -tetracarboxylate,  $\text{C}(\text{CO}_2\text{Et})_2\cdot\text{CH}\cdot\text{CH}_2\cdot\text{CH}(\text{CO}_2\text{Et})_2$ , is isolated as a colourless, viscous liquid, b. p. 223—225°/13 mm. (some decomp.). It is reduced by zinc dust and boiling glacial acetic acid to ethyl butane- $\alpha\alpha\delta\delta$ -tetracarboxylate (cf. Perkin, T., 1894, 65, 579). It is converted by cold saturated alcoholic ammonia at the atmospheric temperature into the corresponding triamide,  $\text{C}_{10}\text{H}_{15}\text{O}_5\text{N}_3$ , small needles, m. p. 230° (decomp.), and by concentrated aqueous ammonia into the tetra-amide,  $\text{C}_8\text{H}_{12}\text{O}_4\text{N}_4$ , small, colourless needles, m. p. 257° (decomp.) after incipient change at 238°. Hydrolysis of the ester with alcoholic potassium hydroxide solution and subsequent addition of lead acetate leads to the production of the salt,  $\text{C}_{10}\text{H}_{10}\text{O}_{16}\text{Pb}_3$ , which seems to be derived from a tribasic acid; the latter is an amorphous, brittle, colourless mass. The unsaturated ester is converted by bromine in the presence of chloroform in ethyl  $\alpha\beta\delta$ -tribromobutane- $\alpha\alpha\delta\delta$ -tetracarboxylate,

hexagonal pyramids, m. p. 61—63°, which, when distilled under diminished pressure or warmed with pyridine, passes into ethyl  $\Delta^4$ -butadiene- $\alpha\alpha\delta\delta$ -tetracarboxylate,  $\text{C}(\text{CO}_2\text{Et})_2\cdot\text{CH}\cdot\text{CH}\cdot\text{C}(\text{CO}_2\text{Et})_2$ , colourless, matted needles, m. p. 56—57°. The latter substance is reduced by zinc dust and glacial acetic acid to ethyl butane- $\alpha\alpha\delta\delta$ -tetracarboxylate. The ester is converted by fuming hydrochloric acid into a mixture of  $\beta\gamma$ -diethoxy-n-butane- $\alpha\alpha\delta\delta$ -tetracarboxylic acid, colourless needles, m. p. 132°, which evolve carbon dioxide at about 140°, and  $\beta\gamma$ -diethoxy-n-butane- $\alpha\delta$ -dicarboxylic acid, crystalline scales, m. p. 19·5°, b. p. 149°/13 mm. The latter

acid is converted by bromine in the presence of chloroform into *α,δ*-dibromo- $\beta$ - $\gamma$ -di( $\alpha$ ' $\beta$ '-dibromoethoxy)adipic acid,  
 $\text{CO}_2\text{H}\cdot\text{CHBr}\cdot\text{CH}(\text{O}\cdot\text{CHBr}\cdot\text{CH}_2\text{Br})\cdot\text{CH}(\text{O}\cdot\text{CHBr}\cdot\text{CH}_2\text{Br})\cdot\text{CHBr}\cdot\text{CO}_2\text{H}$ ,  
 small, colourless needles, m. p. 77–78°.

The condensation of an excess of  $\alpha\beta$ -dichloroethyl ether with an ethereal suspension of ethyl sodiomalonate at a low temperature leads to the production of *ethyl β-chloro-α-ethoxyethylmalonate*,  
 $\text{CH}_3\text{Cl}\cdot\text{CH}(\text{OEt})\cdot\text{CH}(\text{CO}_2\text{Et})_2$ , a colourless, mobile liquid, b. p. 149–152°/13 mm. H. W.

**Selective Hydrogenation.** THOMAS PERCY HILDITCH and CHARLES WATSON MOORE (*J. Soc. Chem. Ind.*, 1923, 42, 15–17).—Conclusive proof of the preferential saturation of one or more double bonds in the catalytic hydrogenation of compounds containing several unsaturated linkings is furnished by a study of the hydrogenation of a number of natural oils and of the esters prepared from their fatty acids. Samples were withdrawn at intervals corresponding with a drop of 10–20 in the iodine value, and the proportion of saturated and unsaturated fatty acids and of oleic to linoleic acid was calculated from the iodine values obtained. It was found that the amount of saturated derivatives present did not increase until the amount of linoleic derivatives had fallen to 10%, or even less, of the mixture. It is clear, therefore, that linolein and linolenin are almost completely hydrogenated to olein before the unsaturated centre in olein is affected. In the case of the free acids, the strong attraction between the free carboxyl group and the metal dwarfs to some extent the relative activities of the different unsaturated systems. G. F. M.

**Perilla Oil.** K. H. BAUER (*Chem. Umschau*, 1923, 30, 9–11; cf. A., 1922, i, 983).—The unsaturated acids obtained by debrominating the bromides soluble in a mixture of ether and glacial acetic acid were oxidised by Hazura's method with alkaline permanganate. The resulting mixture of hydroxy-acids was extracted successively with light petroleum, ether, and water. The light petroleum extract was a viscid, yellow oil, which slowly deposited a crystalline mass and was similar to the corresponding extract of the oxidation products of the total fatty acids from perilla oil. The crystalline deposit consisted of palmitic acid, and was due to the imperfect separation of saturated and unsaturated acids given by the lead salt-benzene method. The ethereal extract consisted of a white, crystalline mass of dihydroxystearic acid, m. p. 131°, and comprised 5.7% of the debrominated acids originally oxidised. Glycerides of oleic acid are therefore present in perilla oil. The aqueous extract comprised only 1.5% of the original acids oxidised, and its nature was not determined. Very small quantities of linusic and isolinusic acids were isolated from the insoluble residue. It appears from this that the linolenic acid from perilla oil gives the same hexabromostearic acid as that from linseed oil, but on oxidation of the former with alkaline permanganate, in addition to linusic and isolinusic acids, an isomeric hexahydroxystearic acid is obtained, which is not obtained from the linolenic acid from linseed oil.

The linolenic acid obtained by the debromination of hexabromo-stearic acid is, however, different from that originally brominated, and only yields 14% of its weight of insoluble bromides. It therefore appears that conclusions as to the presence or absence of isomeric linolenic acids cannot be based only on the behaviour on bromination.

H. C. R.

**The Equilibrium between Formaldehyde and Amino-acids in Aqueous Solution.** JULIUS SVEHLA (*Ber.*, 1923, 56, [B], 331—337).—The reaction between amino-acids and formaldehyde in dilute aqueous solution has been examined, and the corresponding equilibrium constants are calculated in accordance with the equation:  $C_{\text{Alk}} \times C_{\text{acid}} / C_{\text{Alk-acid}} = K$ . The following values are observed: glycine, 1.73; alanine, 14.1; valine, 28.9; leucine, 38.8; aspartic acid, 25.7; glutamic acid, 30.7. Leucylglycine appears to react with two molecular proportions of formaldehyde in dilute aqueous solution.

In the cases of the simpler amino-acids, the measurements are effected by determining the freezing points of solutions of the acid and formaldehyde singly and when mixed. With the more complex acids, the results are deduced from determinations of their solubility in pure water and in formaldehyde solutions of certain concentrations at 25°.

H. W.

**Action of Aldehydes on Mixtures of Sulphites and Hydrogen Sulphites.** J. ESTALELLA (*Anal. Fis. Quim.*, 1922, 20, 437—441).—When formaldehyde is added to a solution containing potassium sulphite and potassium hydrogen sulphite, the following reactions take place successively: (1)  $\text{H}\cdot\text{CHO} + \text{KHSO}_3 = \text{OH}\cdot\text{CH}_2\cdot\text{SO}_3\text{K}$  and (2)  $\text{H}\cdot\text{CHO} + \text{K}_2\text{SO}_3 + \text{H}_2\text{O} = \text{OH}\cdot\text{CH}_2\cdot\text{SO}_3\text{K} + \text{KOH}$ . The gradual liberation of potassium hydroxide is demonstrated by the reddening of added phenolphthalein. A similar reaction is given by a solution of potassium sulphite alone in the presence of carbon dioxide, but the red colour with phenolphthalein is then non-persistent. It is suggested that the presence of carbon dioxide in the distillate may interfere with the estimation of volatile acid in wines.

G. W. R.

**Density and the Refractive Index of Mixtures of Acetaldehyde and Water or Ethyl Alcohol.** E. VAN AUBEL (*Bull. Acad. roy. Belg.*, 1921, 160—162).—Mainly a question of priority. Attention is also directed to some values for the coefficient of thermal expansion of certain mixtures of acetaldehyde and water.

E. E. T.

**Syntheses by Means of Mixed Organo-zinc Derivatives: Propylglyoxal.** E. E. BLAISE (*Compt. rend.*, 1922, 175, 1216—1218).—The action of oxalyl chloride on  $\alpha$ -hydroxyisobutyric acid yields oxalylbisoxoisobutyric acid. The dichloride of this acid on treatment with zinc propyl iodide forms a mixture of the bisoxalacetaloxyisobutyrate of dibutyl and of propylglyoxal. Alcoholysis of the mixture leaves the former substance unchanged, and decomposes the latter into ethyl hydroxyisobutyrate and the

h\*

acetal of propylglyoxal. The action of methyl alcohol on the mixture of acetals yields the *dimethylacetal* of *propylglyoxal*,  $C_5H_8CO\cdot CH(OMe)_2$ . This is a mobile, colourless liquid, b. p. 65–66°/14 mm., which forms a *disemicarbazone* crystallising from acetic acid with one molecule of the solvent, m. p. above 250°, and a *osazone*, yellow needles, m. p. 105°. On boiling with 3% sulphuric acid, hydrolysis takes place with liberation of *propylglyoxal*, a yellowish-green liquid, b. p. 36°/16 mm.; the vapour is of the same colour as the liquid. On being kept in a sealed tube, it becomes viscous and of paler colour; in air it is rapidly oxidised. It has a powerful reducing action and rapidly restores the colour of Schiff's reagent. H. J. E.

**The Nomenclature of Steric Series.** A. WOHL and K. FREUDENBERG (*Ber.*, 1923, 56, [B], 309–313).—In two almost simultaneous communications (Wohl, A., 1922, i, 626; Freudenberg, A., 1922, i, 623) systems of nomenclature of steric series have been proposed which differ from one another in certain details; in order to avoid confusion, the following system is advocated.

The direction of the rotation of a compound is indicated by prefixing the sign + or – to the name, thus (+)-glucose, or (+)-tartaric acid. This is the only possible system in the case of many substances, such as tannins and alkaloids, which cannot at present be brought into line with the stereochemical structure of the sugars. It is, however, open to the objection that it is not distinctive in cases in which the sign of rotation varies with the concentration (malic acid), or in which inversion occurs when the acid is converted into its salt (*e.g.*, glyceric acid).

The genetic relationship to glyceraldehyde is adopted as the determining factor in the nomenclature of hydroxy-acids and sugars. The *d*-form of the aldehyde is written as shown in the annexed formulae I and II. All compounds containing one asymmetric carbon atom which are genetically related to glyceraldehyde and in which the hydroxyl group is to the right of or below the asymmetric carbon atom belong to the *d*-series.

In the cases of compounds with several carbon atoms, each of the latter is indicated in the same manner; the system is distinctive for the sugars themselves and their unsymmetrical derivatives. If the carbonyl group is written at the top of or to the right of the formula, the position of the steric model is established, and also the configurative formula. The order of the single carbon atoms is from below to above or from left to right, because this sequence corresponds with the relation of the sugars to glyceraldehyde; (+)-glucose is thus designated *ddld*. [This necessitates an inversion of Fischer's symbols in the cases of gulose, idose, xylose, and threose, as proposed previously by Rosanoff (A., 1906, ii, 320).]

The mode of formulating symmetrical derivatives of the sugars according to this system is somewhat indefinite. Thus, saccharic

acid is lettered *dddd* if regarded as derived from glucose and *U* if considered as formed from gulonic. In such cases, it is recommended that the relationship to the more important sugar should be expressed, or, as this is arbitrary, that merely the sign of rotation should be given, (+)-saccharic acid. H. W.

**Optical Rotatory Power of Sugars in Hydrochloric Acid.** ISZLÓ ZECHMEISTER (*Z. physikal. Chem.*, 1922, 103, 316—336).—The optical rotation and its change with time has been determined at 0° and 10° in concentrated hydrochloric acid (40.6%) solutions at various concentrations of the following sugars: dextrose, alactose, mannose, arabinose, xylose, rhamnose, and lævulose. The results show that aldo-hexoses and aldo-pentoses in cold concentrated hydrochloric acid solution undergo a measurable reversible change which is evidenced by a large increase of the specific rotation to a constant end-value. The position of the end-value is determined by the concentration of the hydrochloric acid, and in highly concentrated acid exceeds the value of  $[\alpha]_D$  for the  $\alpha$ -form of the sugar in water solution. In the case of dextrose, in 46.7% hydrochloric acid the value of  $[\alpha]_D^{12}$  is +202°. Lævulose shows a somewhat irregular behaviour. Possibilities for the explanation of this phenomenon are considered. J. F. S.

**The Biochemical Synthesis of an  $\alpha$ -D-Mannoside Starting from Manna.** H. HÉRISSEY (*Compt. rend.*, 1922, 175, 1110—1112; cf. A., 1921, i, 628).—The action of dried and powdered cerise seeds [as a source of  $\alpha$ -D-mannosidase] on manna in presence of methyl alcohol results in the formation of  $\alpha$ -methyl-D-mannoside. The manna was not present in pure condition, but as carob seed (*Ceratonia siliqua*), which contains a considerable amount of the carbohydrate. The author suggests that in such a reaction the sugar may have at the moment of formation a different structure from that which it possesses in the crystalline form, and indicates the possibility of preparing glucosides directly from starch by a suitable choice of enzymes. H. J. E.

**The Constitution of the Disaccharides. VII. Sucrose.** WALTER NORMAN HAWORTH and WILFRED HERBERT LINNELL (*T.*, 1923, 123, 294—301).

**The Constitution of the Disaccharides. VIII. Sucrose.** WALTER NORMAN HAWORTH and JAMES GIBB MITCHELL (*T.*, 1923, 123, 301—310).

**Pentosans. III. Purity of Xylan from Straw Cellulose.** EMIL HEUSER and MARIA BRADEN (*J. pr. Chem.*, 1922, [ii], 104, 250—264).—It is shown that the lignin content of crude xylan, even if it contains methylxylan, may be estimated by Zeisel's method, but the method is a rough one only, since it depends on knowledge of the methoxyl content of lignin, in the isolation of which loss of methoxyl occurs (cf. Heuser and Wenzel, A., 1921, ii, 715). A sample of xylan prepared by the modified method of Salkowski (cf. A., 1903, i, 206) is in this way shown not to contain

lignin; the absence of methyl pentosan is demonstrated by the method of Tollens and Ellet (A., 1905, ii, 210).

By a modification of Schulze's process (*Z. physiol. Chem.*, 1892, 16, 403) xylan is prepared from bleached straw cellulose, in 19% yield, containing 93.8% of pure xylan and 0.94% of ash. Precipitation of xylan by calcium chloride solution from a nearly neutralised alkaline solution, and further purification by dialysis, gives a product containing 12.2% of ash, corresponding with a yield of 22% of ash-free xylan. Further purification by solution in sodium hydroxide solution and reprecipitation with acid reduces the ash content to 0.6%, but the yield is then only 15%. These results compare unfavourably with those obtained by the more expensive Salkowski method.

W. S. N.

**Pentosans. IV. Hydrolysis of Xylan by Dilute Acids.** EMIL HEUSER and LUDWIG BRUNNER (*J. pr. Chem.*, 1922, [ii], 104, 264—281).—It is shown that when xylan is hydrolysed by means of hot hydrochloric acid solution (5% or 12%) or by hot dilute sulphuric acid (12%), the xylose produced is partly converted into humin-like substances before the parallel conversion into furfuraldehyde commences; if, however, the hydrolysis is continued, the formation of furfuraldehyde is mainly accountable for the loss of xylose. The course of the hydrolysis is followed by a method already described (Heuser and Kürschner, A., 1922, i, 113).

W. S. N.

**Acetyl Derivatives of Xylan.** EMIL HEUSER and PAUL SCHLOSSER (*Ber.*, 1923, 56, [B], 392—395).—The presence of two free hydroxyl groups in xylan, established previously by the production of a dimethyl derivative (Heuser and Ruppel, A., 1922, i, 810) is confirmed by the isolation of a diacetate.

The treatment of xylan with boiling acetic anhydride or with acetyl chloride at the atmospheric temperature does not yield a completely acetylated product, since the acetates are to some extent hydrolysed by the acetic or hydrochloric acid produced simultaneously. This action can be limited by the addition of pyridine, and under these conditions the diacetate, a colourless powder, is obtained in 90% yield. Unlike cellulose, therefore, xylan may be acetylated in the absence of a catalyst, but the experimental conditions can be made less drastic if such an agent is present. The most suitable substance for this purpose is concentrated nitric acid; sulphuric acid is objectionable on account of its tendency to yield charred products. Dry, powdered xylan reacts with difficulty, but can be brought into a more suitable condition by allowing it to swell in water and removing the latter by treating the product successively with acetic acid and acetic anhydride.

H. W.

**Cellulose Chemistry. II. The Action of Dry Hydrogen Bromide on Carbohydrates and Polysaccharides.** HAROLD HIBBERT and HAROLD S. HILL (*J. Amer. Chem. Soc.*, 1923, 45, 176—182; cf. *J. Ind. Eng. Chem.*, 1921, 13, 256, 334).—The authors have repeated the work of Fenton and Gostling (T., 1898,

73, 554; 1899, 75, 423; 1901, 79, 361; 1909, 95, 1334) on the action of dry hydrogen bromide on carbohydrates and polysaccharides. Contrary to the results of these workers, a yield of 12% of  $\omega$ -bromomethylfurfuraldehyde was obtained from pure dextrose, from  $\alpha$ -methylglucoside the yield was 15%, and from cellobiose 27%. In one case, from a dry cotton cellulose, a 56% yield was obtained. The formation of  $\omega$ -bromomethylfurfuraldehyde under these conditions is not, therefore, alone characteristic of ketoses and ketose derivatives, but also takes place with aldoses and related compounds. Its formation from cellulose is thus no criterion as to the presence of ketone groupings in this product (cf. Cross and Bevan, "Cellulose," 1918). W. G.

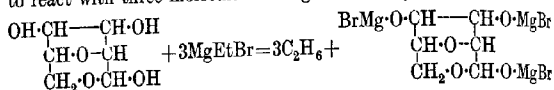

**Chemical Decomposition of Cellulose by Oxidation under Pressure.** FRANZ FISCHER, HANS SCHRADER, and WILHELM TREIBS (*Ges. Abh. Kennt. Kohle*, 1921, 5, 211—220; from *Chem. Zentr.*, 1922, iii, 1185).—By oxidation of cellulose in sodium carbonate solution under pressure at 200°, 42% of the material used is obtained as acids. Of these, about 11% consists of oxalic acid, and more than 50% of acetic acid. About 25% (9% of the original cellulose) consists of non-volatile acids extractable with ether: these include fumaric acid and succinic acid. Small amounts of formaldehyde are also obtained. On heating cellulose under pressure, both hydrolysis and oxidation take place. Sugars may be formed which undergo oxidation. G. W. R.

[Effect of] **Heating under Pressure of Alkaline Solutions obtained from the Oxidation under Pressure of Cellulose and Lignin.** FRANZ FISCHER, HANS SCHRADER, and WILHELM TREIBS (*Ges. Abh. Kennt. Kohle*, 1921, 5, 311—318; from *Chem. Zentr.*, 1922, iii, 1186).—By heating the solution of sodium salts, obtained by heating 100 g. of dry cellulose at 200° in the presence of sodium carbonate solution, at 400° under pressure, the following were obtained: gases, 6.5 litres; oils, 1.5 g.; tarry substances, 2.7 g.; volatile acids (acetic and formic acids), 0.28 equivalent; ether acids, 1.2 g. (0.014 equivalent). Similarly treated, 100 g. of lignin gave: gases, 3.4 litres; oil, 1.6 g.; volatile acids, 0.17 equivalent (including benzoic acid, 0.7 g.); humic acids, 2.0 g.; sphthalic acid, 1.8 g.; acids extractable by ether, 1.1 g. G. W. R.

[Effect of] **Heating Cellulose and Lignin under Pressure in the Presence of Water and Aqueous Alkalis.** FRANZ FISCHER and HANS SCHRADER (*Ges. Abh. Kennt. Kohle*, 1921, 5, 332—359; from *Chem. Zentr.*, 1922, iii, 1184—1185).—Cellulose is increasingly decomposed with rising temperature when heated under pressure in the presence of water, giving compounds, including acids, soluble in water, and gaseous products, principally carbon dioxide, and some hydrogen; comparatively little solid residue remains. Decomposition takes place slowly at 200°, but more completely at 300°. Lignin also gives carbon dioxide, but the principal product is black carbonaceous material. Sulphite liquors, heated at 300°,

give insoluble substances which are precipitated as a black powder. Probably association to larger molecules takes place. Cellulose in the presence of alkalis is more resistant than lignin when heated under pressure at 200°. At 300°, strong decomposition takes place with evolution of carbon dioxide and formation of small amounts of an oil of powerful odour together with formic acid, acetic acid, and other decomposition products. Lignin, heated under pressure with aqueous alkalis, goes completely into solution at 200°, with formation of humic substances. On heating the dark brown solution at 300°, the humic acids associate and separate as dark brown or black masses. Wood, peat, bituminous coal, and anthracite heated under pressure with potassium hydroxide solution behave according to their composition. G. W. R.

**Magnesyl Derivative of Cellulose.** D. COSTA (*Gazzetta*, 1922, 52, ii, 362—365).—On the basis of Green's formula for cellulose, the latter, in virtue of its three hydroxyl groups, might be expected to react with three molecules of magnesium ethyl bromide:

The author finds that, at a temperature not exceeding 35°, an ethereal solution of magnesium ethyl bromide acts on cellulose, yielding ethane and a greenish-grey compound which shows the fibrous structure of the original cellulose and has the composition of a *magnesium cellulose bromide*,  $\text{C}_6\text{H}_7\text{O}_5\cdot\text{MgBr}\cdot\text{Et}_2\text{O}$ . This compound reacts with avidity with water, giving cellulose and magnesium bromohydroxide. It was not found possible to introduce more than the one bromomagnesium residue into the cellulose molecule. T. H. P.

[**Cellulose Copper Compounds.**] WILHELM TRAUBE (*Ber.*, 1923, 56, [B], 268—274).—Hess and Messmer's conception (*A.*, 1921, i, 401; 1922, i, 988) of the constitution of the compounds formed by the solution of cellulose in copper oxide-amine solutions is identical in its essential features with that previously put forward by Traube (*A.*, 1922, i, 115, 718). In the author's opinion, the electrolytic observations of Hess and Messmer (*loc. cit.*) do not justify the conclusions which they have based on them and an alternative interpretation of the results is given. H. W.

**Physico-chemical Studies of Cellulose Nitrates in Organic Media.** I and II. J. NEWTON KUGELMASS (*Rec. trav. chim.*, 1922, 41, 751—754, 755—763).—A study of the physical properties of solutions of cellulose nitrate (nitrogen content 11.9%) in ether and in alcohol prepared at a low temperature. Estimation of the nitrogen content of the solute in each case (11.20% and 14.02% respectively) showed that the ethereal solution apparently contains cellulose dinitrate, whilst the constituent soluble in alcohol is the trinitrate. The viscosity of the ethereal solution compared with that of the pure solvent is greater at temperatures

below  $-20^{\circ}$  but identical above this point, the maximum difference observed being in the neighbourhood of  $-90^{\circ}$ . Other properties of the ethereal solution are similar to those of aqueous solutions of colloids.

H. J. E.

**Constitution of Pine Lignin. III.** PETER KLASON (*Ber.*, 1923, 56, [B], 300—308; cf. *A.*, 1920, i, 822; 1922, i, 324).—The preparation of  $\beta$ -lignosulphonic acid and of its  $\beta$ -naphthylamine and calcium salts is described. New analyses lead to the formula  $C_{19}H_{18}O_6$  for  $\beta$ -lignin in place of  $C_{19}H_{18}O_5$  proposed previously (*A.*, 1920, i, 822). The calcium salt is converted by molten potassium hydroxide into protocatechuic acid.

$\alpha$ -Lignin is regarded as formed by the condensation of two molecules of coniferyl aldehyde in such a manner that two hydrogen atoms have undergone change in position and the annexed formula is assigned to it:

In this formula, the skeletons of guaiacol, pyrocatechol, *m*- and *p*-cresols, and methyl-, ethyl-, and *n*-propyl-cresols are present, and all these substances are present in pine tar. The formation of methyl alcohol, allyl alcohol, and 2-methylfuran is also explained.

Attempts are described to effect the synthesis of coniferyl aldehyde by the condensation of vanillin with acetaldehyde in dilute aqueous solution in the presence of sodium hydroxide. In place of the desired compound, however, its dimeric form is obtained, which, in virtue of the aldehyde group, can react with one molecular proportion of sulphite, but is distinguished from acraldehyde-lignin by its inability to combine with a second molecular proportion of sulphite as a consequence of the presence of the double bond.  $\alpha$ -Lignin, however, after very mild treatment with calcium hydroxide, loses the ability to become converted into  $\alpha$ -lignosulphonic acid. It is considered that the synthetic dimeric coniferyl alcohol is identical with hemi- $\alpha$ -lignin.

Further attempts to prepare coniferyl aldehyde by the regulated oxidation of coniferin did not lead to the desired result, the dimeric form being again obtained.

A condensation product,  $C_{30}H_{27}O_5N$ , from vanillin and  $\beta$ -naphthylamine is incidentally described.

H. W.

**Chemical Decomposition of Lignin by Oxidation under Pressure.** FRANZ FISCHER, HANS SCHRADER, and WILHELM TREIBS (*Ges. Abh. Kennt. Kohle*, 1921, 5, 221—229; from *Chem. Zentr.*, 1922, iii, 1185).—Lignin, prepared by treatment of wood with concentrated hydrochloric acid (Willstätter and Zechmeister), contains 60.6% of carbon, 4.5% of hydrogen, 12.6% of water, and 3.3% of ash. When shaken with 2.5*N*-sodium carbonate solution in the presence of air at  $200^{\circ}$ , a dark coloured solution is obtained, 44% of the lignin remaining undissolved, a total of 0.101 equivalent of acid being obtained of which 0.0185 is volatile in steam. Carbon

dioxide, equivalent to 8.4% carbon, 0.60% of a neutral oil, 9.6% of humic acids, and 4.2% of ether-soluble non-volatile acids are also obtained. By oxidation for forty hours, 0.55 equivalent of acids (including 0.18 equivalent volatile in steam, and 0.16 equivalent of oxalic acid), 18.9% of non-volatile acids (by extraction with ether), 0.31% of mellitic acid, and 4.2% of water soluble calcium salts were formed.

G. W. R.

[Effect of] Oxidation and Heating under Pressure of Humic Substances from Sucrose. FRANZ FISCHER, HANS SCHRADER, and WILHELM TREIBS (*Ges. Abh. Kennt. Kohle*, 1921, 5, 230—234; from *Chem. Zentr.*, 1922, iii, 1186).—Humic substances obtained by the method of Conrad and Guthzeit were submitted to oxidation under pressure at 200° for eight and three-quarter hours. 2.2 Equivalents of acid were thus formed: the solution obtained was clear and reddish-brown. After acidifying, 0.27 equivalent of volatile acid (acetic acid) was obtained by steam distillation. The residue, by extraction with ether, yielded a comparatively small amount of a viscid oil. After evaporation to dryness, the residue was heated with water at 400° for three hours. The gases formed included carbon dioxide and the vapour of a substance, most probably furan. The solid products were light coloured and slightly tarry. By steam distillation an oil of basic odour was obtained. The volatile acids included the lower fatty acids and benzoic acid. *iso*Phthalic acid and terephthalic acid were also obtained.

G. W. R.

Thermal Decomposition of Tetramethylammonium Fluoride. F. GONZÁLEZ NÚÑEZ (*Anal. Fis. Quim.*, 1922, 20, 539—549).—Tetramethylammonium fluoride is obtained in 89% yield by exact neutralisation of the hydroxide with hydrofluoric acid. When decomposed by heating in the presence of water catalysed by metals (silver, platinum, or copper) the products are nitrous oxide, methyl fluoride, trimethylamine, and methane.

G. W. R.

Mercuric Compounds with Hexamethylenetetramine. R. DOURIS and G. BEYTOUT (*Compt. rend.*, 1923, 176, 107—109).—When mercuric sulphate is dissolved in water to which is added drop by drop just sufficient sulphuric acid to prevent the formation of the basic sulphate and the solution is added to an equimolecular solution of hexamethylenetetramine the double *mercuric hexamethylenetetramine sulphate*,  $C_6H_{12}N_4SO_4Hg.H_2O$ , m. p. 177° (decomp.), is obtained. The double *cyanide* decomposing at 216° and the double *acetate* decomposing at 120° are similarly prepared. In these salts the corrosive action of the ordinary mercuric salt is considerably diminished and the therapeutic action increased.

W. G.

Hexamethylaminetetramine-betaine. F. BOEDECKER and J. SEPP (*Ber. Deut. pharm. Ges.*, 1922, 32, 339—344).—The reaction between hexamethylenetetramine and chloroacetic acid is so violent that profound decomposition ensues. The hydrochloride of the

betaine is formed in good yield, however, when these substances react in chloroform solution. The well-characterised compounds of hexamethylenetetramine-betaine with metallic halides are obtained in good yield by the action of hexamethylenetetramine on aqueous solutions of salts of chloroacetic acid. The hydrochloride of hexamethylenetetramine-betaine,  $C_6H_{12}N_4Cl \cdot CH_2 \cdot CO_2H$ , obtained as indicated above in chloroform solution, forms large crystals which by treatment with moist silver oxide give the hydrated form of hexamethylenetetramine-betaine,  $OH \cdot C_6H_{12}N_4 \cdot CH_2 \cdot CO_2H$ , lustrous plates, easily soluble in water with neutral reaction and slightly sweet taste. By the action of hexamethylenetetramine on aqueous sodium chloroacetate, the sodium salt,  $C_6H_{12}N_4Cl \cdot CH_2 \cdot CO_2Na \cdot H_2O$ , was obtained. Addition of aqueous cadmium chloride to its aqueous solution causes the double salt,  $(C_6H_{12}N_4Cl \cdot CH_2 \cdot CO_2)_2Cd \cdot CdCl_2 \cdot 4H_2O$ , to crystallise. This on treatment with hydrochloric acid gives the acid cadmium salt,  $C_6H_{12}N_4Cl \cdot CH_2 \cdot CO_2H \cdot CdCl_2 \cdot H_2O$ . By the action of zinc chloride and mercuric chloride respectively on the solution of the sodium salt, double salts,  $C_6H_{12}N_4Cl \cdot CH_2 \cdot CO_2Na \cdot ZnCl_2 \cdot H_2O$  and  $(C_6H_{12}N_4Cl \cdot CMe \cdot CO_2)_2Hg \cdot HgCl_2$ , were obtained. P. M.

**The Chlorination of Esters of Amino-acids.** WILHELM TRAUBE and HEINRICH GÖCKEL (*Ber.*, 1923, 56, [B], 384–391).—Ethylurethane can be smoothly converted by chlorine or hypochlorous acid in aqueous solution into *N*-chloroethylurethane,  $NHCl \cdot CO_2Et$ . Under similar conditions, the conversion of the esters of amino-acids into the corresponding monochlorinated derivatives does not appear to be possible, the dichloro-compounds being almost invariably produced.

Ethylurethane dissolved in water is converted by gaseous chlorine at the atmospheric temperature into *N*-chloroethylurethane, b. p. 101–102°/30 mm., the yield being 80% of that theoretically possible. It solidifies at 0°. The potassium salt,  $C_3H_5O_2NClK \cdot 2H_2O$ , lustrous prisms which explode at 300°, the hygroscopic sodium salt, and the silver salt, a colourless powder, are described. *N*-Chloro-*N*-methylurethane,  $NMeCl \cdot CO_2Et$ , a colourless liquid, b. p. 57°/30 mm., is prepared by the chlorination of *N*-methylurethane or by the action of methyl sulphate and potassium hydroxide on chloroethylurethane. The latter is transformed by potassium hydroxide and benzoyl chloride into *N*-chloro-*N*-benzoylurethane, a pale yellow liquid which was not prepared in the homogeneous condition; its formation is established by the reduction of the product of the reaction to *N*-benzoylurethane, m. p. 110°. The action of ethyl chloroformate on chloroethylurethane in aqueous alkaline solution leads to the production of a mixture of *N*-dichloroethylurethane, b. p. 73°/20 mm., and ethyl imino-dicarboxylate, m. p. 50°; the primarily formed ethyl chloroimino-dicarboxylate appears to react with a portion of the chloroethylurethane liberated by hydrolysis of the potassium salt in accordance with the scheme:  $NCl(CO_2Et)_2 + Cl \cdot NH \cdot CO_2Et \rightarrow NH(CO_2Et)_2 + NCl_2 \cdot CO_2Et$ .

The action of chlorine on an aqueous solution of ethyl amino-

acetate leads to the formation of *ethyl dichloroaminoacetate*,  $\text{NCl}_2\text{CH}_2\text{CO}_2\text{Et}$ , a yellow liquid. *Ethyl dibromoaminoacetate* is prepared from ethyl aminoacetate and sodium hypobromite; both dihalogenated compounds are unstable. *Ethyl  $\alpha$ -dichloroamino-propionate*,  $\text{NCl}_2\text{CHMeCO}_2\text{Et}$ , is an extremely unstable, pale yellow liquid. H. W.

**Synthesis of  $\gamma$ -Amino- $\beta$ -hydroxybutyric Acid.** MASAJI TOMITA (*Z. physiol. Chem.*, 1923, 124, 253—258).— $\gamma$ -Phthalimido- $\beta$ -hydroxybutyronitrile, m. p. 132°, is prepared by the action of potassium cyanide on  $\alpha$ -chloro- $\gamma$ -phthalimido- $\beta$ -hydroxypropane. When hydrolysed with concentrated sulphuric acid at water-bath temperature, it yields  $\gamma$ -amino- $\beta$ -hydroxybutyric acid, m. p. 214°, which gives a marked biuret reaction, and forms a crystalline copper salt. When heated just above its melting point, it loses water to form 4-hydroxy-2-pyrrolidone, m. p. 118°, and on exhaustive methylation the betaine is formed, isolated as its chloroaurate,  $\text{C}_4\text{H}_{11}\text{O}_3\text{N}_2\text{HAuCl}_4$ , citron-yellow needles, m. p. 180—182°. It has been suggested that carnitine may be the betaine of  $\gamma$ -amino- $\beta$ -hydroxybutyric acid, but carnitine chloroaurate melts about 30° lower than that of the betaine described above. There remains, however, the possibility that carnitine may be the optically active form. W. O. K.

**A Polymeride of Hydrocyanic Acid.** CH. BEDEL (*Compt. rend.*, 1923, 176, 168—171).—When azulmin, resulting from the polymerisation of hydrocyanic acid, is extracted with ether, a yellowish-brown, crystalline substance is obtained. If this material is crystallised from aqueous solution after decolorising it with animal charcoal and the resulting mother-liquors are concentrated in the presence of charcoal, a colourless, crystalline substance is obtained. It has m. p. 179° (decomp.), and molecular-weight determinations show it to be a tetrameride of hydrogen cyanide. When decomposed by dilute mineral acids, it gives for each molecule one molecule of hydrogen cyanide. When decomposed by barium hydroxide, it gives glycine, ammonia, and a small amount of barium carbonate, but principally barium oxalate. With alcoholic potassium hydroxide and chloroform, it gives the odour of carbonylamine. From its behaviour the author considers it to be a hydrocyanide of aminopropanedinitrile (cf. Wippermann *Ber.*, 1874, 7, 767). W. G.

**The Nitriles of Fluoro- and Difluoro-acetic Acids.** FRED SWARTS (*Bull. Soc. chim. Belg.*, 1922, 31, 364—365).—These substances were prepared by distillation of the corresponding amide with phosphoric oxide. *Fluoroacetonitrile* is a colourless liquid of penetrating odour, b. p. 81.8—82°,  $d_4^{20}$  1.0730. It is slightly soluble in water and reacts rapidly with potassium hydroxide. *Difluoroacetonitrile*, b. p. 22.8—23.4°, is a colourless, mobile liquid  $d_4^{20}$  1.1130, very sparingly soluble in water and reacting vigorously with potassium hydroxide. A specimen kept for several years did not undergo polymerisation. H. J. E.

**The Action of Organomagnesium Compounds on Nitriles.**  
***n*-Butyronitrile.** FRANTZ BAERTS (*Bull. Soc. chim. Belg.*, 1922, 31, 421—426).—The results obtained with *n*-butyronitrile are exactly parallel to those previously obtained by the author with propionitrile (A., 1922, i, 817). The chief product of *n*-butyronitrile and magnesium ethyl bromide was ethyl propyl ketone (about 40%). Diethylpropylcarbinol was also formed together with termolecular cyanopropane,  $(\text{PrCN})_3$ , and a substance not previously isolated which proved to be  $\alpha$ -butyrylbutyronitrile, a liquid, b. p.  $216^\circ$ , semicarbazone, m. p.  $88$ — $90^\circ$ . P. M.

**Constitution of Allyl Cyanide.** P. BRUYLANTS (*Bull. Acad. roy. Belg.*, 1920, 479—486).—Pyridine and  $\gamma$ -chlorobutyronitrile when heated together give allyl cyanide, b. p.  $114$ — $116^\circ/757$  mm.,  $d_4^{20}$  0.8318,  $n_D^{20}$  1.41438. The product is not accompanied by the nitrile of cyclopropanecarboxylic acid, which, however, is formed by the action of dry potassium hydroxide on the above chloro-compound, whilst the latter with sodium ethoxide affords a mixture of the cyclic nitrile and  $\gamma$ -ethoxybutyronitrile.

By the removal of the elements of water from  $\alpha$ -hydroxybutyronitrile, a product (b. p.  $115$ — $116^\circ/763$  mm.,  $n_D^{20}$  1.41692) is obtained, which, from its convertibility into two known dibromo-amides is thought to be a mixture of crotononitrile and isocrotononitrile. Potassium cyanide and allyl bromide interact to give the same mixture. E. E. T.

**Prussian Blue and Turnbull's Blue.** V. ERICH MÜLLER [with HANS LAUTERBACH] (*J. pr. Chem.*, 1922, [ii], 104, 241—258).—The insoluble Prussian blue, precipitated by adding potassium ferrocyanide solution to ferric chloride solution in the proportion non-ionisable iron : ionisable iron = 0.75, consists of ferric ferrocyanide, which is converted by further addition of potassium ferrocyanide into potassium ferric ferrocyanide. Equimolecular proportions of potassium ferrocyanide and ferric chloride do not, however, give pure potassium ferric ferrocyanide, because the reaction  $\text{Fe}_4^{III}[\text{Fe}^{II}(\text{CN})_6]_{13}^{IV} + \text{K}_4\text{Fe}^{II}(\text{CN})_6 \rightleftharpoons 4\text{KFe}^{III}[\text{Fe}^{II}(\text{CN})_6]^{IV}$  is reversible, and the further change  $\text{KFe}^{III}[\text{Fe}^{II}(\text{CN})_6]^{IV} + \text{K}_4\text{Fe}^{II}(\text{CN})_6 = \text{K}_5\text{Fe}^{III}(\text{CN})_6 + \text{K}_3\text{Fe}^{II}[\text{Fe}^{II}(\text{CN})_6]^{IV}$  occurs, so that the main product,  $\text{KFe}^{III}[\text{Fe}^{II}(\text{CN})_6]^{IV}$ , contains traces of potassium ferrous ferrocyanide and ferric ferrocyanide in solid solution. The insoluble Turnbull's blue, formed by adding potassium ferri-cyanide to ferrous chloride solution in the proportion non-ionisable iron : ionisable iron = 0.75, is  $\text{KFe}^{II}\text{Fe}_3^{III}[\text{Fe}^{II}(\text{CN})_6]^{IV}$ , which with further amounts of potassium ferricyanide passes into potassium ferric ferrocyanide :

$\text{KFe}^{II}\text{Fe}_3^{III}[\text{Fe}^{II}(\text{CN})_6]^{IV} + \text{K}_3[\text{Fe}^{III}(\text{CN})_6]^{III} = 4\text{KFe}^{III}[\text{Fe}^{II}(\text{CN})_6]^{IV}$ . Again, the proportion non-ionisable iron : ionisable iron = 1.0 gives a solid solution, consisting mainly of  $\text{KFe}^{III}[\text{Fe}^{II}(\text{CN})_6]^{IV}$ , with traces of  $\text{KFe}^{II}\text{Fe}_3^{III}[\text{Fe}^{II}(\text{CN})_6]^{IV}$ , and also of  $\text{Fe}_4^{III}[\text{Fe}^{II}(\text{CN})_6]^{IV}$ , formed according to the equation  $\text{KFe}^{II}\text{Fe}_3^{III}[\text{Fe}^{II}(\text{CN})_6]^{IV} + \text{K}_3\text{Fe}^{III}(\text{CN})_6 = \text{Fe}_4^{III}[\text{Fe}^{II}(\text{CN})_6]^{IV} + \text{K}_4\text{Fe}^{II}(\text{CN})_6$ . The formation of

Prussian blue and of Turnbull's blue, when non-ionisable iron : ionisable iron = 1, may then be expressed respectively by :

and

Suppose for the formation of Turnbull's blue a ferricyanide solution is used containing 1 mol. KCl per mol.  $\text{FeCl}_2$ , so that there can be written  $\text{FeCl}_2 + \text{K}_3\text{Fe}^{\text{III}}(\text{CN})_6 + \text{KCl} = \text{KFe}^{\text{III}}[\text{Fe}^{\text{II}}(\text{CN})_6]^{\text{IV}} + 3\text{KCl}$ , then both reactions become fully identical if the primary change is :  $\text{FeCl}_2 + \text{K}_3\text{Fe}^{\text{III}}(\text{CN})_6 + \text{KCl} = \text{FeCl}_3 + \text{K}_4\text{Fe}^{\text{II}}(\text{CN})_6$ . Equimolecular solutions of (a)  $\text{FeCl}_3$  and  $\text{K}_4\text{Fe}^{\text{II}}(\text{CN})_6$ , (b)  $\text{FeCl}_2$  and  $\text{K}_3\text{Fe}^{\text{III}}(\text{CN})_6 + \text{KCl}$  therefore give the same end-product, the Prussian blue and Turnbull's blue formed under these conditions being identical.

These views, which agree with results already obtained analytically (cf. A., 1909, i, 142, 705, 706; 1911, i, 844; 1914, i, 504, 1058), have now been fully confirmed by following the various reactions potentiometrically; the potential of a platinum electrode immersed in one reagent is compared with that of a normal electrode ( $\text{Hg}, \text{Hg}_2\text{Cl}_2, \text{N} - \text{KCl}$ ) after each addition of the second reagent. The results are shown graphically, the volume of the added constituent being plotted against the compensating ohmic resistance. The formation of solid solutions is deduced from the gradual slope of the relevant curves, whilst the intersection at the point "non-ionisable iron : ionisable iron = 1" of all four curves, corresponding with the pairs of reagents (1)  $\text{FeCl}_3$  and  $\text{K}_4\text{Fe}^{\text{II}}(\text{CN})_6$ , (2)  $\text{FeCl}_2$  and  $\text{K}_3\text{Fe}^{\text{III}}(\text{CN})_6 + \text{KCl}$ , is considered proof of the identity of the Prussian blue and the Turnbull's blue formed under these conditions.

W. S. N.

**Derivatives of Semioxamizide. I. Ketonic Semioxamazones.** FORSYTH JAMES WILSON and ERIC CHARLES PICKERING (T., 1923, 123, 394—397).

**Oxidation of Cadets' Oil. Preparation of Cacodylic Acid.** HENRI GUINOT (*J. Pharm. Chim.*, 1923, [vii], 27, 55—64).—The mixture of cacodyl and cacodyl oxide obtained by the dry distillation of potassium acetate and arsenious oxide is oxidised quantitatively to cacodylic acid by aqueous hypochlorite solutions, and the same reaction may be utilised for its estimation, the excess of hypochlorite added being determined by the addition of potassium iodide and titration of the liberated iodine with thiosulphate. For the preparation of cacodylic acid, the oil is agitated with the requisite amount of sodium hypochlorite solution in presence of hydrochloric acid, the completion of the oxidation being indicated by the disappearance of the odour of cacodyl or by the use of potassium iodide-starch paper. The acid solution thus obtained is neutralised with sodium hydroxide, using Congo-red as indicator, and is then evaporated to a small bulk, and the sodium chloride which separates is removed. The syrup is finally evaporated to dryness, and extracted with 96% alcohol. The alcoholic extract on cooling deposits pure cacodylic acid in 70% yield, and another 20% may

be obtained from the mother-liquors. Alternatively, cacodylic acid may be obtained in 80% yield by direct oxidation by means of oxygen of a solution of the oil in dry acetone to which slightly more than the amount of water theoretically required by the following equations is gradually added as the absorption of oxygen proceeds:  $(\text{AsMe}_2)_2\text{O} + \text{H}_2\text{O} + \text{O}_2 = 2\text{AsMe}_2\text{O} \cdot \text{OH}$  and  $2(\text{AsMe}_2)_2 + 2\text{H}_2\text{O} + 3\text{O}_2 = 4\text{AsMe}_2\text{O} \cdot \text{OH}$ . The absorption of oxygen is very rapid and is with advantage moderated somewhat, otherwise a certain amount of arsenious acid will be formed. The cacodylic acid formed crystallises from the solution in an almost pure condition. The anodic oxidation of a solution of the oil in 20% sulphuric acid also gives a 70–80% yield of cacodylic acid, but this method does not present any practical advantage.

G. F. M.

**Permanence of the Grignard Reagent.** HENRY GILMAN and CHARLES H. MEYERS (*J. Ind. Eng. Chem.*, 1923, 15, 61).—Observations extending over more than six months showed that the numerous Grignard reagents examined underwent no appreciable deterioration or decomposition during this period, when kept in ethereal solution (in some cases highly concentrated) and adequately protected from the moisture, carbon dioxide, and oxygen of the atmosphere by storage in glass-stoppered containers.

G. F. M.

**The Optimum Condition for the Preparation of Magnesium Ethyl Iodide.** HENRY GILMAN and CHARLES H. MEYERS (*J. Amer. Chem. Soc.*, 1923, 45, 159–165).—Using the methods of analysis previously described (*ibid.*, 150) and a special reaction flask by means of which it was possible to withdraw aliquot portions for analysis, a study was made of the factors which influence the yield of magnesium ethyl iodide and, therefore, to some extent the yield of other Grignard reagents. The results indicate that there is a steady increase in the percentage of Grignard reagent formed when the rate of addition of ethyl iodide is progressively decreased, but that no advantage is gained by extending the time for the addition of 9.5 g. of ethyl iodide beyond forty-five minutes. Stirring during the addition of the ethyl iodide and for fifteen minutes after the addition is completed is desirable, and then it is not necessary to warm the mixture under a reflux condenser. Any large excess of magnesium does not affect the yield. When no precautions are taken to exclude the moisture and carbon dioxide of the air, the yield is lowered. Under a standard set of conditions the finer the grade of magnesium turnings used, the higher is the yield.

W. G.

**Reducing Action of Grignard Reagents.** B. A. BUYLLA and E. OLAY (*Anal. Fis. Quim.*, 1922, 20, 599–600).—Metallic alkylloxides react with Grignard reagents, giving hydrocarbons. For example, magnesium ethyl iodide and sodium methoxide in the presence of anhydrous xylene with ethyl ether or dimethyl-aniline as catalyst react as follows:  $\text{MgEtI} + \text{MeONa} = \text{C}_2\text{H}_4 +$

$\text{CH}_4 + \text{MgO} + \text{NaI}$ . Ethyl magnesium iodide and sodium amyl-oxide give ethylene and an unidentified liquid hydrocarbon.

G. W. R.

**The Preparation of Methylmercuric Acetate and the Isolation of Methylmercuric Hydroxide.** M. CANNON SNEED and J. LEWIS MAYNARD (*J. Amer. Chem. Soc.*, 1922, **44**, 2942—2947).—The substance described by Otto (*Annalen*, 1870, **154**, 199) as methylmercuric acetate, m. p. 142—143°, could not have been pure. The authors have obtained pure methylmercuric acetate by four different methods, namely, (1) the action of mercuric acetate on mercurydimethyl in methyl alcohol, (2) the neutralisation of methylmercuric hydroxide with glacial acetic acid, (3) the action of methylmercuric hydroxide on ethyl acetate, (4) the interaction of silver acetate and methylmercuric iodide. So prepared, it has, in all cases, m. p. 128°, and is very soluble in water, acetic acid, and ethyl alcohol. It is also one of the products of the thermal decomposition of mercurous acetate in an atmosphere of nitrogen.

*Methylmercuric hydroxide*, m. p. 95°, is readily obtained by the action of moist silver oxide on methylmercuric iodide in methyl alcohol. It is a very weak base, being alkaline to litmus but acid to phenolphthalein in aqueous solution. It is a strong vesicant even in dilute solutions.

W. G.

**Ethyl Ether- and Ethanol-mercuri-salts.** K. A. HOFMANN and KURT LESCHEWSKI (*Ber.*, 1923, **56**, [B], 123—129).—Hofmann and Sand have assigned the constitutions  $\text{X} \cdot \text{Hg} \cdot \text{C}_2\text{H}_5 \cdot \text{OH}$  and  $\text{X} \cdot \text{Hg} \cdot \text{C}_2\text{H}_5 \cdot \text{O} \cdot \text{C}_2\text{H}_5 \cdot \text{HgX}$  to the products obtained by the action of ethylene on mercury salts, whereas according to Manchot (*A.*, 1920, i, 519, 720) they are to be regarded as additive products,  $\text{C}_2\text{H}_5 \cdot \text{HgX} \cdot \text{OH}$ , analogous to the compound obtained from cuprous chloride and carbon monoxide. The readiness with which they evolve ethylene appears to support Manchot's conception, but, on the other hand, the same tendency is observed with undoubtedly atomic compounds, such as ethylene dibromide, which yields ethylene when treated with magnesium or organomagnesium compounds and magnesium ethyl bromide, which evolves the gas when treated with manganese chloride. The mercuri-salts are somewhat sharply differentiated from Manchot's compounds of cuprous chloride with ethylene or carbon monoxide by their much greater stability towards non-acidic reagents and heat. The strongest argument in favour of the conception of the existence of an alcoholic group in ethanolmercuri-compounds lies in the observation that they evolve alcohol and aldehyde when boiled with potassium hydroxide solution and leave a residue of metallic mercury and mercuride,  $\text{C}_2\text{H}_5\text{O}_2\text{Hg}_2$ . The change proceeds slowly when potassium hydroxide alone is used, but can be greatly accelerated by the addition of potassium iodide; under the latter conditions, 50% of the organic portion of ethanolmercuri-chloride is obtained as alcohol and aldehyde, the production of the latter being attributable to the oxidising action of mercury oxide in the

strongly alkaline medium. The action is very difficult to explain Manchot's mode of formulation is adopted, since the persistence of portions of the mercuri-compound until the conclusion of the change shows that hydratisation of ethylene does not occur previously to its evolution and an alkaline suspension of mercury oxide is found to be without appreciable action on pre-formed ethylene.

H. W.

**Primary Tar.** I. FRANZ SCHÜTZ (*Ber.*, 1923, 56, [B], 162—169).—An examination of the tar formed by the carbonisation of coal obtained from the neighbourhood of Dortmund in rotary furnaces at 500—600°. The coal yields about 23% of volatile products (about 7% tar, 6% aqueous distillate, and 10% gas) and about 77% of semi-coke. It is found that the most volatile portions of the neutral oils contain only very small quantities of paraffins and larger amounts of unsaturated hydrocarbons. They consist mainly of aromatic and hydroaromatic hydrocarbons. The presence of benzene, toluene, and xylene is established, and that of their higher homologues is shown to be probable. The presence of considerable amounts of hydroaromatic hydrocarbons may be regarded as extremely probable. The absence of naphthalene is confirmed. Ketones, particularly acetone, are present. Phenol occurs in considerable quantity, its amount being very much greater than in coke-oven tar. Traces of acetaldehyde and acetonitrile are observed. Toly! mercaptans are present in very small amount together with a sulphide, b. p. 150—160°, which appears to belong to the aliphatic series.

H. W.

**Preparation of Petroleum from Rosin.** SEIJI KWAI (*J. Chem. Ind. Japan*, 1922, 25, 1421—1424).—On distilling a mixture of rosin (acid value 162.1 and saponification value 178.3) and dried Japanese acid earth (ratio 1 : 0.5—1 : 2) at 160° to 350° under ordinary pressure, an oily distillate, *d* 0.88, was produced; the yield being about 60% of the rosin used. This had an odour and a marked fluorescence similar to that of natural petroleum and is approximately composed of naphthenes, about 50%, aromatic hydrocarbons 40%, and unsaturated hydrocarbons (probably terpenes) 10%.

K. K.

**Lely's Benzene Formula.** S. C. J. OLIVIER (*Chem. Weekblad*, 1923, 20, 27).—A criticism of the triangular formula (this vol., i, 99). The synchronous rotation of the hydrogen atoms or substituents attached to the secondary carbon atoms is a dangerous conception; applied to the four dissimilar atoms or groups attached to an asymmetric carbon atom, it would invalidate the possibility of optical isomerism. Further, the existence of meta- and ortho-substituted benzenes is only possible if the phase of the synchronous rotation is unalterable in molecular collisions, reactions, etc. The facts with regard to substitution generally are only explained by Lely's arguments which could equally easily be employed to lead to exactly opposite conclusions.

S. I. L.

**The Essentials of a Benzene Formula.** H. J. PRINS (*Chem Weekblad*, 1923, 20, 28; see preceding abstract).—Lely's formula fails entirely to explain the characteristic properties of the aromatics as contrasted with the aliphatic compounds; if benzene contained  $-\text{CH}_2-$  groups, all the mono-substituted benzenes should act as if the substituent were united to a carbon atom still united to hydrogen e.g., phenol like a secondary alcohol. Quinol would have the group  $\text{C} \begin{smallmatrix} \text{OH} \\ \text{OH} \end{smallmatrix}$  and ring formation as in phthalic anhydride should occur equally readily with para-substituted derivatives, as terephthalic acid.

S. I. L.

**The Structural Formula for Benzene.** H. A. J. SCHOUTISSEN (*Chem. Weekblad*, 1923, 20, 29; see preceding abstracts).—The four valencies of the primary carbon atoms in Lely's formula lie in one plane, and in an angle of  $130^\circ 32'$ , making with each other angles of  $35^\circ 16'$  and  $60^\circ$ . The valencies of the three secondary carbon atoms lie along the edges of a tetrahedron. Such a distribution in a stable system like benzene is unthinkable.

A space-model of benzene based on the Lewis-Langmuir theory is suggested, which has the necessary symmetry and valency-distribution. In one phase it coincides with that of Pauly (*A.*, 1919, i, 120), whilst by a rotation of each of the carbon atoms through  $90^\circ$  or  $270^\circ$  the configuration of Armstrong, Baeyer, and Claus is obtained.

S. I. L.

**Cymene as a By-product of the Hydrolysis of Wood.** EMIL HEUSER, L. ZEH, and B. ASCHAN (*Z. angew. Chem.*, 1923, 36, 37–38).—*p*-Cymene occurs in appreciable quantities amongst the volatile products of the hydrolysis of wood with dilute mineral acids under pressure, and originates probably from the action of the acid on the  $\alpha$ -pinene derived from the resins of the wood. It was isolated from the light oil which collects on the surface of the distillate. This was treated with sodium hydrogen sulphite to remove furfuraldehyde, and with 40% potassium hydroxide to remove volatile acids, and then fractionally distilled. The fraction boiling between  $174^\circ$  and  $179^\circ$  consisted largely of *p*-cymene which was identified by conversion into barium *p*-cymenesulphonate. The total content of *p*-cymene in the light oil was estimated at 4–5%.

G. F. M.

**1-Methyl-3-tert.-amylbenzene.** G. CHARRIER [with M. GALLOTTI and E. ZAPPELLI] (*Gazzetta*, 1922, 52, ii, 317–323).—By the action of *tert*-amyl chloride on toluene in presence of aluminium chloride, the author has obtained the compound prepared by Essner and Gossin (*A.*, 1885, 517) by treating toluene in presence of aluminium chloride with either active or inactive amyl chloride or amylene. The conclusion drawn by these authors that this compound is 1-methyl-3-*tert*-amylbenzene is confirmed, its description in Beilstein (edition III, ii, 36) as *m*-isoamyltoluene being inaccurate.

1-Methyl-3-*tert*-amylbenzene is a colourless, mobile, refractive liquid with an odour of pine resin,  $d_4^{20}$  0.8930,  $d_4^{25}$  0.8673,  $d_4^{30}$  0.8082.

When oxidised by either permanganate or dilute nitric acid, it yields isophthalic acid. The action of fuming nitric acid at  $-10^{\circ}$  gives two isomeric *mononitro*-derivatives, which are uncrystallisable, pale yellow liquids with a pungent odour of musk: (1) b. p.  $160-161^{\circ}/25$  mm.,  $d_4^{20}$  1.0675, and (2) b. p.  $165-169^{\circ}/23$  mm.,  $d_4^{20}$  1.0825; the nitro-groups probably occupy the 2-, 4-, or 6-positions.

The action of chlorine on the hydrocarbon in presence of iodine yields two *monochloro*-derivatives, probably the 4- and 6-compounds: (1) a mobile, highly refractive liquid with a delicate odour of aniseed, b. p.  $242-243^{\circ}/750.25$  mm.,  $d_4^{20}$  0.9769, and (2) a highly refractive liquid with a similar odour to the previous compound, b. p.  $247-248^{\circ}/750.25$  mm.,  $d_4^{20}$  1.0111; neither isomeride solidifies at  $-25^{\circ}$ .

The action of bromine on the hydrocarbon in the dark at  $0^{\circ}$  gives 4-(or 6) *bromo-1-methyl-3-tert.-amylbenzene*, which is a highly refractive liquid with a pleasing ethereal odour, b. p.  $262-264^{\circ}/752.38$  mm.,  $d_4^{20}$  1.2143, and remains liquid at  $-25^{\circ}$ . T. H. P.

**The Influence of some Substituents in the Benzene Ring on the Mobility of the Chlorine in the Side-chain in its Relation to the Problem of Substitution in the Benzene Ring. II.** S. C. J. OLIVIER (*Rec. trav. chim.*, 1922, 41, 646-651; cf. A., 1922, i, 646).—A development of the work described in the previous paper. The influence of the position of the substituent is less pronounced the greater the retarding influence of that substituent on mobility. A table is given showing the values of the reaction constants calculated from the rate of saponification of various compounds, that for benzyl chloride itself being taken as unity. From this it is seen that at a higher temperature the reaction velocities generally tend to become of identical value, the smaller increasing with temperature, the greater remaining approximately constant. The retarding influence of the negative substituents is thus less pronounced at a higher temperature. The list of substituents in their order of influence as previously given (*loc. cit.*) is now amplified by addition of bromine and is  $p\text{-Me} > o\text{-Me} > m\text{-Me} > \text{H} > p\text{-Cl} > p\text{-Br} > o\text{-Cl} > o\text{-Br} > m\text{-Cl} > m\text{-Br} > m\text{-NO}_2 > o\text{-NO}_2 > p\text{-NO}_2$ . H. J. E.

**Some Constants of Phenylchloroform [Tri-*o*-chlorotoluene].**

FRED. SWARTS (*Bull. Soc. chim. Belg.*, 1922, 31, 375-377).—A redetermination of some of the physical constants of tri-*o*-chlorotoluene gave the following values: m. p.  $-4.75^{\circ}$ ; b. p.  $110.7^{\circ}/23$  mm.;  $220.7^{\circ}/761$  mm.;  $d_4^{20}$  1.3775. The cryoscopic constant has the notably high value 93.1. Moist air in contact with the substance causes rapid and considerable lowering of the freezing point, previous values for which are  $-22.5^{\circ}$  (Haas, A., 1893, ii, 357),  $-17^{\circ}$  (Altschul, A., 1895, ii, 206), and  $-8.1^{\circ}$  (Timmermans, A., 1914, ii, 168). H. J. E.

**Aromatic Sulphinic Acids.** E. KNOEVENAGEL and A. RÖMER (*Ber.*, 1923, 56, [B], 215-217).—Sodium benzenesulphinate in the presence of ether is converted by one or less molecular proportion of phosphorus trichloride into *phenyl benzenethiosulphonate*,

$\text{Ph}\cdot\text{SO}_2\cdot\text{SPh}$ , m. p.  $45^\circ$ , which is reduced by an excess of the tri-chloride to diphenyl disulphide, m. p.  $60^\circ$ . Under similar conditions, thionyl chloride yields benzenesulphonyl chloride, phenyl benzenethiosulphonate, and some nitrogen sulphide. Sulphuryl chloride gives benzenesulphonyl chloride.

Salts of the type  $\text{CHR}\cdot\text{NHR}'\cdot\text{SO}_2\text{Ph}$  are obtained by the action of molar amounts of benzenesulphonic acid and anils in the presence of ether at the atmospheric temperature. These are decomposed by solution in alcohol and subsequent addition of ether in accordance with the equations:  $\text{CHR}\cdot\text{NHR}'\cdot\text{SO}_2\text{Ph} + \text{H}_2\text{O} = \text{R}\cdot\text{CHO} + \text{R}'\cdot\text{NH}_2 + \text{Ph}\cdot\text{SO}_2\text{H}$ ;  $3\text{Ph}\cdot\text{SO}_2\text{H} = \text{Ph}\cdot\text{SO}_3\text{H} + \text{Ph}\cdot\text{SO}_2\cdot\text{S}\cdot\text{Ph} + \text{H}_2\text{O}$ ;

$\text{Ph}\cdot\text{SO}_2\text{H} + \text{Ph}\cdot\text{NH}_2 = \text{Ph}\cdot\text{NH}_2 \begin{smallmatrix} \text{H} \\ \text{SO}_2\text{Ph} \end{smallmatrix}$ . The salts derived from the following anils have the melting points placed in brackets: benzylideneaniline ( $82^\circ$ ); benzoinanil ( $158-160^\circ$ ); acetophenoneanil ( $136^\circ$ ); dypnoneanil ( $130^\circ$ ). Acetoneanil and *N-isopropenyl-N-methylaniline* appear to react in a more complicated manner.

Ferrous and ferric benzene sulphinates are almost insoluble in water; the nickel, cobalt, copper, and cadmium salts dissolve to the extent of 10–15% in boiling water, the manganese salt to 20%, and the lead and silver salts to 40%. Aluminium and chromium salts do not give a precipitate with benzenesulphonic acid. The manganese, copper, and lead salts are soluble in dilute acetic acid; the cadmium salt dissolves in glacial acetic acid, whereas the nickel, cobalt, and iron salts require dilute mineral acids to bring them into solution. H. W.

**Certain Derivatives of Anthracene.** F. KEHRMANN, RAOUL MONNIER, and MARIE RAMM (*Ber.*, 1923, 56, [B], 169–174).—Attempts are described to obtain dyes of the type

The nitration of 9:10:10-triphenyl-9:10-dihydroanthran-9-ol (Haller and Guyot, A., 1904, i, 660) could not be satisfactorily accomplished.

9-Phenyl-10:10-diethyl-9:10-dihydroanthran-9-ol, colourless needles, m. p.  $111-112^\circ$ , is prepared by the action of magnesium phenyl bromide on 10:10-diethyl-9-anthrone; it forms coloured carbonium salts with sulphuric, perchloric, and nitric acids. When dissolved in concentrated sulphuric acid it is converted by alcohol into 10-phenyl-9:9-diethyl-9:10-dihydroanthracene, colourless needles, m. p.  $135-136^\circ$ . 9:9-Diethyl-9:10-dihydroanthracene, slender, colourless needles, m. p.  $210^\circ$ , is obtained by the reduction of diethylanthrone with zinc dust and acetic acid.

9:10-Diphenyl-9:10-dihydroanthra-9:10-diol (Haller and Guyot, *loc. cit.*) gives an intense indigo-blue solution in concentrated sulphuric acid; it appears to be transformed thereby into anthraquinone, 9:10-diphenylanthracene, and an intensely reddish-yellow substance which has not been completely investigated. The nitration and reduction of the products will be described subsequently. H. W.

**Preparation of Cyclic Amines.** A. MAILHE (*Bull. Soc. chim.*, 1923, [iv], **33**, 83—86).—The direct hydrogenation of the hydrazones or ketazines of cyclic ketones over a nickel catalyst at 180° leads, as in the case of similar open-chain compounds, to the formation of primary amines accompanied by a small proportion of the corresponding secondary amines. Thus the hydrazone of 1:3-dimethyl-4-cyclohexanone is converted into 1:3-dimethyl-4-cyclohexylamine, a colourless liquid, b. p. 169—171°,  $d^{20}_4$  0.8810, which rapidly absorbs carbon dioxide from the air and gives a hydrochloride, m. p. 278°, and a phenylcarbamide, m. p. 174°. Similarly, carvylamine is obtained together with a small quantity of dicarvylamine by the hydrogenation of carvone ketazine. Carvylamine boils at 205—210°, and forms a hydrochloride, m. p. 198°. Menthylamine obtained by the hydrogenation of menthonehydrazone, a colourless liquid, b. p. 243°, over nickel at 200°, is a strong base, b. p. 212°, giving a hydrochloride, m. p. 274°. Dimethylamine produced at the same time boils at 305—310°, and gives a hydrochloride, m. p. 207°. G. F. M.

**Formation of Phenylcarbylamine and Nitrobenzene in Aqueous Aniline Solutions.** HERMANN KUNZ-KRAUSE and PAUL MANICKE (*Ber. Deut. pharm. Ges.*, 1922, **32**, 232—236).—The formation of products with an odour of carbylamine when aniline and water are exposed for several months to sunlight does not take place if the aniline is pure, the products in this case being of a tarry nature and dissolving in concentrated sulphuric acid with a Bordeaux-red colour. Mono-methyl- and ethyl-anilines and toluidine behave in the same way as aniline. On the other hand, minute traces of nitrobenzene are formed even with pure aniline under the above conditions. P. M.

**Action of Alcohols on Anilides.** ALPHONSE MAILHE (*Bull. Soc. chim.*, 1923, [iv], **33**, 81—83).—Although the hydrogen atom of the  $\text{NH}=\text{N}$  group of secondary arylamines is readily replaced by an alkyl group by the action of aliphatic alcohols in presence of dehydrating catalysts such as thoria or alumina, the aromatic amides cannot be similarly alkylated, as the water produced in the reaction causes the hydrolysis of the amides. So, for example, the catalysis of a mixture of acetanilide and methyl alcohol vapours over alumina at 370—380° results, not in the formation of methyl-acetanilide, but of a mixture of aniline, methylaniline, and dimethylaniline and acetic acid, together with small quantities of dimethyl ether. Other anilides and toluidides behave in a similar manner either with methyl or ethyl alcohol. With propyl alcohol, propylene and water are formed, and the anilide is hydrolysed; but no propylanilines are produced. G. F. M.

**The Action of Sodammonium on Aniline and its Homologues.** M. PRION (*Compt. rend.*, 1922, **175**, 1213—1216).—The action of sodammonium on cyclic amines in which the nitrogen is directly linked to the benzene ring affords a ready method of preparing the sodium derivatives of these amines. Only

monosodium derivatives were obtained; these are formed as readily with primary as with secondary amines. No reaction occurs with benzylamine. Monosodioaniline,  $\text{NPhNa}$ , is a pale yellow, transparent solid decomposed by water with formation of aniline and sodium hydroxide and reacting with alkyl halides yielding substituted anilines (cf. Titherley, T., 1897, 71, 464). *Sodio-ethylaniline*,  $\text{NPhEtNa}$ , is a pale yellow solid; *monosodio-toluidine*,  $\text{C}_6\text{H}_4\text{MeNHNa}$ , a pale yellow solid; *sodiodiphenylamine*,  $\text{NPh}_2\text{Na}$ , a white solid; they all show properties similar to those of monosodioaniline. The method of preparation consists in mixing the amine with sodammonium and an excess of liquid ammonia and allowing the mixture to remain in contact under pressure at the ordinary temperature for some days. Attempts to prepare disodium derivatives were unsuccessful.

H. J. E.

**Reaction between Aniline and Chloroacetic Acid. I.** RYUZABURO NODZU and SHIGERU KOMATSU (*Mem. Coll. Sci. Kyoto*, 1922, 6, 73—76).—Among the products of interaction of aniline (1.04 mol.) and chloroacetic acid (1 mol.) in a closed vessel at  $100^\circ$  were isolated and identified chloroacetanilide, diketodiphenylpiperazine, phenyliminodiacetic acid and its mono-anilide, and phenylglycine. The mono-anilide is probably formed by the interaction of phenylglycine and chloroacetanilide.

E. H. E.

**Optically Active Dyes. I.** A. W. INGERSOLL and ROGER ADAMS (*J. Amer. Chem. Soc.*, 1922, 44, 2930—2937).—In order to investigate the question as to whether the absorption of dyes by animal or vegetable fibres is a physical or chemical phenomenon the authors propose to prepare a number of optically active dyes and to examine the rate of absorption of the optical isomerides. With this purpose in view, they have prepared two such pairs of dyes. *d*- and *l*-aminoPhenylacetic acid have been condensed with *p*-nitrobenzoyl chloride and the products reduced to the corresponding amino-compounds, which were then diazotised and the diazo-compounds coupled with  $\beta$ -naphthol and dimethylaniline, respectively. Preliminary dyeing experiments have been carried out, and although the *d*- and *l*- $\beta$ -naphthol dyes were absorbed in the same relative amounts over short as well as long periods, the experiments with the two dimethylaniline dyes indicated that one is absorbed more rapidly than the other. The following new compounds are described: *r-p-Nitrobenzamidophenylacetic acid*, m. p.  $184^\circ$  (corr.), its *ethyl ester*, m. p.  $140^\circ$  (corr.). *r-p-Aminobenzamidophenylacetic acid*, m. p.  $152^\circ$  (corr.), and its *hydrochloride*, m. p.  $213^\circ$  (decomp.). *l-p-Nitrobenzamidophenylacetic acid*, m. p.  $163^\circ$  (corr.),  $[\alpha]_D^{20} - 86.56^\circ$ , its *ethyl ester*, m. p.  $155^\circ$  (corr.),  $[\alpha]_D^{20} - 67.7^\circ$ . *l-p-Aminobenzamidophenylacetic acid*, m. p.  $168-169^\circ$  (corr.),  $[\alpha]_D^{20} - 93.75^\circ$ , and its *hydrochloride*, m. p.  $220-222^\circ$  (decomp.). *d-p-Nitrobenzamidophenylacetic acid*, m. p.  $163^\circ$  (corr.),  $[\alpha]_D^{20} + 86.13^\circ$ , its *ethyl ester*, m. p.  $155^\circ$  (corr.),  $[\alpha]_D^{20} + 67.4^\circ$ . *d-p-Aminobenzamidophenylacetic acid*, m. p.  $168-169^\circ$  (corr.),  $[\alpha]_D^{20} + 93.63^\circ$ , and its *hydrochloride*, m. p.  $220^\circ$  (decomp.). The

$\alpha$ -aminobenzoyl acid when diazotised and the product coupled with  $\beta$ -naphthol gave a compound, m. p.  $252^\circ$ , the *l*-acid similarly gave a compound, m. p.  $238^\circ$ ,  $[\alpha]_D^{25} -27.25^\circ$ , and the *d*-acid a compound, m. p.  $238^\circ$  (corr.),  $[\alpha]_D^{25} +28.50^\circ$ . When diazotised and the product coupled with dimethylaniline, the *l*-acid gave a compound, m. p.  $189-190^\circ$ , and the *d*-acid a compound, m. p.  $188-189^\circ$ .

W. G.

**Catalytic Preparation of *o*-Toluidine.** C. O. HENKE and O. W. BROWNE (*J. Physical Chem.*, 1923, 27, 52-64).—In continuation of previous work on the catalytic reduction of nitrobenzene to aniline (A., 1922, i, 445, 535; ii, 833), the authors have investigated the catalytic reduction of *o*-nitrotoluene to *o*-toluidine by means of hydrogen. A nickel catalyst is too active for this purpose, a large part of the *o*-nitrotoluene being reduced beyond the toluidine stage. The highest yield obtained with nickel was 86.8%. Lead catalysts gave slightly higher yields of *o*-toluidine than of aniline, the respective yields in the two cases being 94.6% and 93.4%. Silver, when first used, gave a yield of 99% of *o*-toluidine, but its activity decreased with use, especially at the higher rates of flow of *o*-nitrotoluene. A 97% yield of *o*-toluidine was obtained with a copper catalyst used at  $260^\circ$ , the activity of which had been decreased by use at too high a temperature ( $300^\circ$ ). A copper catalyst prepared by the ignition of copper nitrate at  $415^\circ$  and containing 0.023% of iron gave a yield of 98.3% of *o*-toluidine at  $260^\circ$ . The corresponding yield of aniline was 91.9%. The activity of copper catalysts did not decrease with use. *o*-Nitrotoluene is more easily reduced than nitrobenzene.

**The Isomerism of  $\beta$ -Benzylaminocrotonic Ester, its Reaction with Ferric Chloride, and that of Related Compounds.**

ERICH BENARY (*Ber.*, 1923, 56, [B], 53-55).—The constitutions  $\text{CH}_3\text{Ph}\cdot\text{N}\cdot\text{CMe}\cdot\text{CH}\cdot\text{C}(\text{OH})\cdot\text{OEt}$  and  $\text{CH}_3\text{Ph}\cdot\text{N}\cdot\text{CMe}\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$  have been assigned by Rügheimer (A., 1916, i, 383) to the isomeric ethyl  $\beta$ -benzylaminocrotonates. The author considers this conception highly improbable, since it involves the enolisation of the carbethoxyl group in a series in which enolisation occurs only with difficulty and only when there is an accumulation of negative substituents around the carbon atom. The differing behaviour of the isomerides towards ferric chloride (Rügheimer, *loc. cit.*) is not directly related to their constitution, since the development of the coloration depends on their fission to base and ethyl acetoacetate. A similar dependence of the production of colour on the decomposition of the compound is observed in the cases of ethyl  $\beta$ -aminocrotonate, ethyl  $\beta$ -anilino (or *p*-toluidino)crotonate, methyl  $\beta$ -anilino crotonate, and ethyl ethylenediaminoacetoacetate, but not of their acidic derivatives as far as they have been examined. The colour is not developed if ferric acetate is substituted for ferric chloride.

It is doubtful whether the existence of two forms of ethyl

$\beta$ -benzylaminocrotonate is to be ascribed to *cis-trans*-isomerism or to structural isomerism. H. W.

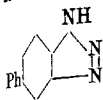

**The Tertiary Amines Derived from Benzhydrylamine.**

MARCEL SOMMELET (*Compt. rend.*, 1922, 175, 1149—1151; cf. A., 1922, i, 333).—The additive product of hexamethylenetetramine and diphenylbromomethane is converted by the action of formic acid into dimethylbenzhydrylamine,  $\text{CHPh}_2\cdot\text{NMe}_2$ , which combines very slowly in the cold with methyl iodide in methyl alcohol to give a *methiodide*, m. p. 211°. In hot solution, the hydriodide is obtained along with the methiodide and also a neutral, oily compound. Diethylbenzhydrylamine, benzhydrylpiperidine, and ethylbenzylbenzhydrylamine behave similarly towards methyl iodide, but in these cases very little, if any, of the methiodide is formed at 100°. If methyl bromide is used instead of methyl iodide, it is not possible to isolate any quaternary salt but only the hydrobromide. If dimethylbenzhydrylamine and methyl bromide are heated together in solution in methyl alcohol in a sealed tube at 100° for forty-eight hours, there is an abundant evolution of methyl ether, and benzhydryl methyl ether,  $\text{CHPh}_2\cdot\text{OMe}$ , and trimethylamine hydrobromide are obtained. If the methyl alcohol is replaced by butyl alcohol, the products are methyl butyl ether and benzhydryl butyl ether. These products may result as follows,  $\text{MeBr} + \text{MeOH} + \text{CHPh}_2\cdot\text{NMe}_2 = \text{Me}_2\text{O} + \text{CHPh}_2\cdot\text{NMe}_2\cdot\text{HBr}$ ;  $\text{CHPh}_2\cdot\text{NMe}_2\cdot\text{Br} = \text{CHPh}_2\cdot\text{Br} + \text{NMe}_3$ , and  $\text{CHPh}_2\cdot\text{Br} + \text{MeOH} + \text{NMe}_3 = \text{CHPh}_2\cdot\text{OMe} + \text{NMe}_3\cdot\text{HBr}$ . W. G.

**Diphenyl. III. Derivatives of Bromodiphenyl.** A. GARCÍA BANÚS and L. MEDRANO (*Anal. Fis. Quím.*, 1922, 20, 475—478; cf. A., 1922, i, 333).—By methylation of 4-bromo-4'-aminodiphenyl, using methyl alcohol and strong hydrochloric acid and heating in sealed tubes for ten hours at 140—150°, 4-bromo-4'-dimethylaminodiphenyl is obtained, which after recrystallisation has m. p. 205—208°. The mother-liquors from the crystallisation of this compound yield the corresponding *methochloride*, m. p. 180—185°. By nitration, 4-bromo-2-nitro-4'-dimethylaminodiphenyl is obtained; it forms large, orange-yellow plates, m. p. 107°. G. W. R.

**Diphenyl. III. Derivatives of Anilinodiphenyl.** A. GARCÍA BANÚS and J. GUITERAS (*Anal. Fis. Quím.*, 1922, 20, 479—485; cf. A., 1922, i, 333).—By boiling *p*-aminodiphenyl with fused sodium and 4:1:3-chlorodinitrobenzene in a reflux apparatus, 4-*op*-dinitroanilinodiphenyl,  $\text{C}_6\text{H}_4\text{Ph}\cdot\text{NH}\cdot\text{C}_6\text{H}_3(\text{NO}_2)_2$ , is obtained; it has m. p. 147° and crystallises in two forms, namely, orange needles from acetic acid and red crystals from toluene. The transformation point from the orange to the red form is 95—105°. By reduction with sodium sulphide, *p*-nitro-*o*-aminoanilinodiphenyl is obtained in platelets, m. p. 188°. 2-*op*-Dinitroanilinodiphenyl is crystalline, m. p. 159°. The corresponding 2-*p*-nitro-*o*-aminoanilinodiphenyl, obtained by reduction with sodium sulphide, forms dark orange platelets, m. p. 151—152°. 4'-Bromo-4-*op*-dinitroanilinodiphenyl from 4:4'-bromoaminodiphenyl forms yellow

leaflets, m. p. 204—205°. 3:4-Diaminodiphenyl gives, with hydrochloric acid and sodium nitrite, 5-phenylbenziminazole (annexed formula); it forms white plates, m. p. 154—155°. 4'-Amino-4-op-dinitroanilinodiphenyl forms small prisms, m. p. 245—247°. 4'-Amino-4-p-nitro-o-aminoanilinodiphenyl forms red platelets, m. p. 201°. 4'-Amino-4-op-diaminoanilinodiphenyl forms grey platelets, m. p. 197°.

G. W. R.

**The Preparation of Phenylimido-phosgene [Phenylcarbylamine Chloride] and the Chlorination of Formanilide.** R. S. BLY, G. A. PERKINS, and W. LEE LEWIS (*J. Amer. Chem. Soc.*, 1922, 44, 2896—2903).—Good yields of phenylthiocarbimide were obtained from thiocarbamilide by heating it under a reflux condenser for several hours with three parts of dilute sulphuric acid (one of acid to 2.5 volumes of water) and subsequently distilling the product with steam. When the thiocarbimide is chlorinated to saturation in solution in carbon tetrachloride or carbon disulphide, a 95% yield of phenylcarbylamine chloride is obtained if the solvent is removed directly by fractional distillation at a pressure of 30 mm. By using the phenylcarbylamine chloride itself as a solvent for subsequent chlorinations the other solvents could be dispensed with.

When formanilide was chlorinated in the cold with or without solvents in the presence of sulphur chloride the product was in all cases 2:4-dichloroformanilide. If the chlorination was conducted in the presence of thiophyl chloride, a series of products was obtained, namely, 2:4-dichloroformanilide, phenylcarbylamine chloride, *p*-chlorophenylcarbylamine chloride, b. p. 135—137°/30 mm., and 2:4-dichlorophenylcarbylamine chloride, b. p. 150—153°/30 mm. *p*-Chlorophenylcarbylamine chloride, when heated with glacial acetic acid, yielded *p*-chloroacetanilide, and with aniline yielded chlorotriphenylguanidine, m. p. 135—136°, as its hydrochloride, m. p. 247—250°. Similarly, 2:4-dichlorophenylcarbylamine chloride gave with acetic acid 2:4-dichloroacetanilide and with aniline 2:4-dichlorotriphenylguanidine, m. p. 129.5—130.5° (corr.) as its hydrochloride, m. p. 207—209° (corr.). The specific gravity of these substituted chlorides increases with the chlorine content but the lachrymatory effect diminishes.

W. G.

**New Derivatives of *p*-Phenethylcarbamide (Dulcin).** MAX BERGMANN, FRANZESKO CAMACHO, and FERDINAND DREYER (*Ber. Deut. pharm. Ges.*, 1922, 32, 249—258; cf. Speckan, A., 1922, 1, 580).—Various derivatives of dulcin (*p*-phenethylcarbamide) have been prepared in an effort to find one which should be more soluble while retaining the sweet taste. *a*-*p*-Phenethyl-*a*-methylcarbamide is more soluble and very sweet, but has a very persistent unpleasant flavour as well. The unpleasant taste is less marked in *a*-*p*-phenethyl-*a*-hydroxyethylcarbamide, but is still sufficient to render it technically useless. These and other compounds of the same type were prepared by the action of potassium cyanate on the hydrochlorides of the corresponding bases in aqueous solution. Derivatives of

dulcin in which an alkyl group is introduced into the primary amino-group are sparingly soluble and have no appreciable sweet taste. The latter compounds were prepared by the action of the corresponding thiocarbimides on phenetidine, whereby the thiocarbamide derivatives were formed, which were converted into the corresponding carbamide compounds by the action of mercuric oxide in acetic acid.

*a-p-Phenetyl-a-methylcarbamide*,  $\text{OEt}\cdot\text{C}_6\text{H}_4\cdot\text{NMe}\cdot\text{CO}\cdot\text{NH}_2$ , was obtained in good yield from potassium cyanate and *N*-methylphenetidine hydrochloride. It forms long needles, m. p. 128–129°. Similarly, *N*-hydroxyethyl-*p*-phenetidine gave *a-p-phenetyl-a-hydroxyethylcarbamide*,  $\text{OEt}\cdot\text{C}_6\text{H}_4\cdot\text{N}(\text{CH}_2\cdot\text{CH}_2\cdot\text{OH})\cdot\text{CO}\cdot\text{NH}_2$ , needles, m. p. 113–115°. Dihydroxypropylphenetidine (Ber., 1922, 55, 2796) gave *a-p-phenetyl-a-dihydroxypropylcarbamide*,  $\text{OEt}\cdot\text{C}_6\text{H}_4\cdot\text{N}[(\text{CH}_2\cdot\text{CH}(\text{OH})\cdot\text{CH}_2\cdot\text{OH})\cdot\text{CO}\cdot\text{NH}_2]$ , crystals, m. p. 138–139°, without sweet taste. By the action of ethyl chloroacetate on *p*-phenetidine, *p-phenetylglycine ethyl ester*,  $\text{OEt}\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CO}_2\text{Et}$ ,

is formed, leaflets, m. p. 33°, b. p. 152°/1 mm. (*amide*, m. p. 146°).

The ester is converted by potassium cyanate into *methyl-a-p-phenethylcarbamido-a-acetate*,  $\text{OEt}\cdot\text{C}_6\text{H}_4\cdot\text{N}(\text{CH}_2\cdot\text{CO}_2\text{Et})\cdot\text{CO}\cdot\text{NH}_2$ , colourless needles, m. p. 86–87°, of slightly bitter taste. With alcoholic ammonia it gives the corresponding *amide*, m. p. 236–237°, without distinctive taste.

*p*-Phenetidine and allylthiocarbimide gave *a-p-phenetyl-b-allylthiocarbamide*, crystals, m. p. 94–95°. With mercuric oxide, it gives *a-p-phenetyl-b-allylcarbamide*, crystallising from alcohol, acetic acid, or ethyl acetate in fine needles, from chloroform in rectangular plates, m. p. 157°.

Similarly, *a-p-phenetyl-b-methylthiocarbamide* crystallises from alcohol in truncated prisms, m. p. 128–128.5°, and *a-p-phenetyl-b-methylcarbamide* forms fine, long, quadrilateral platelets, m. p. 153°. *N*-Methyl-*p*-phenetidine and methylthiocarbimide give *a-p-phenetyl-ab-dimethylthiocarbamide*, truncated prisms, m. p. 99–100°, and *a-p-phenetyl-ab-dimethylcarbamide*, prisms, m. p. 94–95°. Similarly, *a-p-phenetyl-a-methyl-b-allylthiocarbamide* forms long needles, m. p. 68–69°, and *a-p-phenetyl-a-methyl-b-allylcarbamide*, thin needles, m. p. 57–58°. P. M.

**Hydrogenated Polycyclic Ring Systems. I. The Hydrogenation of Phenol and the By-products which are formed thereby.** WALTHER SCHRAUTH, WILHELM WEGE, and FRITZ DANNER (Ber., 1923, 56, [B], 260–268).—The hydrogenation of phenol in the gaseous state and under pressure has been studied in the presence of a nickel-copper catalyst. The arrangement of the apparatus for the first series of experiments is essentially that of Sabatier (*Die Katalyse*, 1914). Phenol is converted into a mixture of cyclohexanol (80–83%), cyclohexanone (6–9%), and smaller quantities of products of lower boiling point which have not been investigated fully; about 10% of the phenol remains unchanged. The results are closely similar to those obtained in

the presence of reduced nickel by Sabatier and Senderens (A., 1904, i, 156) and by Skita and Ritter (A., 1911, i, 272).

Hydrogenation under pressure in the presence of the nickel-copper catalyst is effected according to Schroeter's method (A., 1922, i, 122). It leads essentially to a mixture of cyclohexanol and cyclohexanone, containing about 9–14% of the latter. The volatile products formed during the hydrogenation in the vaporous phase are not observed, their place being taken by dark oils of high boiling point, the amount of which may rise to 10% when the action is unusually prolonged. A condensation appears therefore to occur in which cyclohexanol or more probably cyclohexanone takes part. Since the relative amounts of these substances is hereby undisturbed, it follows that the equilibrium between them is rapidly restored in the presence of the catalyst, which can also induce dehydrogenation (cf. Sabatier and Senderens, A., 1903, 393).

The liquids of high boiling point consist of di- and tri-cyclic condensation products consisting partly of saturated and partly of unsaturated ketones and aldehydes, which are readily converted by further hydrogenation into homogeneous saturated compounds of alcoholic character.

1:3-Dicyclohexylcyclohexane-2-one,  $C_6H_{11} \cdot C_6H_8O \cdot C_6H_{11}$ , long, colourless prisms, m. p. 131–132°, is obtained by the addition of alcohol to the least volatile fractions of the condensation products obtained by the hydrogenation of phenol under pressure. As in analogous cases, the presence of the ketonic group cannot be established by the help of semicarbazide hydrochloride or amino-uanidine hydrochloride, but the constitution of the product is placed beyond doubt by its production by the hydrogenation of 1:3-dicyclohexenylcyclohexane-2-one (cf. Mannich, A., 1907, i, 205). A solution of the ketone in methylcyclohexane is catalytically hydrogenated at 180–190° to a mixture of isomeric 1:3-dicyclohexylcyclohexane-2-ols, colourless needles, m. p. 117°, and a very viscous, colourless liquid, b. p. 220–221°/17 mm.; the latter is slowly converted into the solid variety when preserved. Either alcohol appears to be transformed into a mixture of the cis- and trans-acetate when acetylated. The liquid alcohol is dehydrated by zinc chloride at 200–210° with the formation of 1:3-dicyclohexyl-Δ<sup>1</sup>-cyclohexene, b. p. 204–207°/15 mm.,  $d_{20} 0.9525$ ; the hydrocarbon is also preparable from the solid alcohol, but it is uncertain whether a uniform product is obtained in this manner. It is transformed by hydrogenation in the presence of methylcyclohexane to a mixture of 1:3-dicyclohexylcyclohexanes, long, colourless needles, m. p. 66–67°, and a liquid, b. p. 192–196°/12 mm.,  $d_{20} 0.9335$ .

H. W.

**The Synthesis of Phosphoric Acid Esters. I.** SHIGERU MATSU and SHINICHIRO KUMAMOTO (*Mem. Coll. Sci. Kyoto*, 1922, 6, 45–48).—cycloHexanol when left in contact with phosphoric acid in presence of phosphoric oxide forms a mono-ester,  $\frac{1}{2}H_{11}H_2PO_4$ , colourless crystals, m. p. 77–78°. The soluble VOL. CXXIV. i.

barium salt,  $C_6H_{11}BaPO_4$ , is a white, crystalline substance; the silver salt is insoluble in water. When heated, the free ester and the barium salt are both decomposed into cyclohexene and phosphoric acid or phosphate. The di- and tri-cyclohexyl phosphates could not be obtained.

E. H. R.

**The Action of Iodine on Alkaline Solutions of Phenol.**  
G. VORTMANN (*Ber.*, 1923, 56, [B], 234—246).—In a previous communication it has been shown that iodine reacts with an alkaline solution of phenol to give "di-iodophenol iodide,"

The existence of this compound has been denied by Bougault (A., 1908, ii, 738), by Wilkie (A., 1911, ii, 546; 1912, i, 346), and by Hunter and Woollett (A., 1921, i, 238). Its isolation is now described.

The action of iodine on an alkaline solution of phenol takes place by the initial substitution of the halogen for the sodium atom of the phenoxide and its subsequent migration into the nucleus:  $Ph \cdot O \cdot I \rightarrow C_6H_4I \cdot OH$ . The process is then repeated until tri-iodophenol is produced. Even in the presence of a large excess of iodine, the nature of the product depends essentially on the quantity of alkali. Iodination therefore is effected by the alkali hypiodite. Even in the presence of more than three molecular proportions of sodium hydroxide a compound more highly iodinated than tri-iodophenol is not produced; if the solution is acidified after not more than five minutes, this compound is quantitatively precipitated and is not further affected by the presence of much free iodine in the acid medium. If the phenol solution is not too dilute, tri-iodophenol separates previously to acidification; if it is shaken from time to time in the alkaline suspension, it gradually darkens in colour and passes into a mixture of "di-iodophenol iodide" and tetraiododiphenylenequinone (cf. Lautemann, *Annalen* 1861, 120, 309). Iodination of phenol in the presence of a large excess of alkali yields only di-iodophenol.

Di-iodophenol iodide is most conveniently prepared by the prolonged action of cold sodium hypiodite solution on phenol. The brown mixture of the product with Lautemann's red is treated with acetone in which the former only is soluble to a yellowish-brown solution from which it is reprecipitated by the addition of much water and sodium chloride in the form of irregular dark violet-brown leaflets or scales, m. p. 122°. It slowly loses iodine when exposed to air and gives a violet coloration when its dilute solution in acetone is treated with a little sodium thiosulphate solution.

The mechanism of the formation of Lautemann's red is discussed in detail and appears to be represented by the following equations:  $C_6H_2I_3 \cdot OH + NaIO = C_6H_2I_3 \cdot OI + NaOH$ ;  $C_6H_2I_3 \cdot OI \rightarrow C_6H_2I_2(O) \cdot I_2$ ,  $C_6H_2I_2(O) \cdot I_2 + NaOH = C_6H_2I_2(O) \cdot HI + NaO$ ;  $2C_6H_2I_2(O) \cdot HI = 2HI + O \cdot C_6H_2I_2 \cdot C_6H_2I_2 \cdot O$ .

Oxidation of tri-iodophenol by the requisite amount of potassium

persulphate in the presence of sodium carbonate gives a mixture of di-iodophenol iodide and Lautemann's red. Reduction of the latter in glacial acetic acid solution by stannous chloride and hydrochloric acid gives a colourless compound which appears to be a hydrogenated derivative (cf. Hunter and Woollett, *loc. cit.*).

Phenol may be estimated by treating its solution, which must contain at least four molecular proportions of sodium hydroxide, with an excess of iodine solution; after five minutes the solution is acidified with dilute sulphuric acid, whereby tri-iodophenol is precipitated. The excess of iodine is estimated in an aliquot portion of the supernatant liquor. If the time of action is prolonged beyond five minutes, the precipitate is more or less discoloured, but the consumption of iodine is not thereby changed. H. W.

**The Decomposition of Ethers by Metallic Sodium.** PAUL SCHORIGIN (*Ber.*, 1923, 56, [B], 176—186; cf. A., 1910, i, 547).—Diphenyl ether reacts exothermally with sodium wire at 180—200°, giving phenol (60—75%), benzene (30%), a small quantity of diphenyl, phenol-like products of high boiling point, and carbonised substances. The reaction also occurs in the presence of neutral solvents of suitable boiling point. The reaction is considered to involve the primary addition of sodium to yield the product  $\text{Ph}_2\text{ONa}_2$ , and immediate scission of the latter into sodium phenoxide and sodium phenyl. The latter is decomposed by water (evolved during the production of the complex, pitch-like products) with the formation of benzene and sodium hydroxide. The formation of diphenyl may be ascribed to the direct removal of oxygen from the ether by sodium or to the interaction of sodium phenoxide and sodium phenyl,  $\text{PhNa} + \text{PhONa} = \text{Ph} \cdot \text{Ph} + \text{Na}_2\text{O}$ . The intermediate formation of organo-metallic sodium derivatives is rendered probable by the observation that an extremely vigorous action takes place when dry air is bubbled through the mixture, but, on the other hand, salicylic acid is produced when carbon dioxide is introduced into it, whereas sodium phenyl would be expected to yield benzoic acid.

$\alpha$ -Naphthyl ethyl ether reacts vigorously with sodium at 230—270°, yielding naphthalene,  $\alpha$ -naphthol, carbonised and pitch-like products, ethylene, ethane, and hydrogen. The volume of ethylene formed exceeds that of ethane; the production of butane or butylene could not be established.  $\beta$ -Naphthyl ethyl ether reacts more energetically than the  $\alpha$ -isomeride with sodium, but yields similar products, naphthalene,  $\beta$ -naphthol, ethylene, ethane, and hydrogen. Phenetole does not react to an appreciable extent with sodium at any temperature below its boiling point. At 200—260°, it becomes decomposed into phenol, ethane, ethylene, hydrogen, products of high boiling point, carbonised material, and small quantities of ethyl alcohol. The intermediate formation of organo-metallic substances is established by the observations that the product of reaction becomes heated, sometimes to the point of ignition, when exposed to air, and that propionic acid is produced when it is treated with carbon dioxide.

Benzyl ethyl ether reacts with sodium at 140°, this temperature being much below its boiling point; benzyl alcohol appears to be produced, but owing to an accident, the products could not be fully investigated. isoAmyl ether yields small amounts of isoamylic alcohol when heated with sodium at 200–220° and subsequently at 235–275°.

The experiments show that the desiccation of simple ethers by distillation over sodium is open to suspicion, and that the process is quite unsuitable for fatty-aromatic and aromatic ethers of high boiling point. If the use of sodium is desired, milder conditions should be adopted, and the metal should be removed previously to the distillation of the ether.

H. W.

**Simplified Methods of Preparing certain Organic Substances. I. Nitrophenetoles and Nitroanisoles.** H. VAN ERP (*Ber.*, 1923, 56, [B], 217–221).—The substances are prepared by the action of potassium alkyl sulphates on potassium nitrophenoxides in the presence of a small quantity of glycerol. The latter, after being purified and dehydrated by distillation under diminished pressure, is placed in a  $\frac{1}{2}$ -litre flask provided with a reflux condenser filled with cold water, but with both tubes closed; an intimate mixture of the potassium compounds, previously desiccated at 140° and 100°, respectively, is added; and the mixture is heated in an oil-bath, usually at about 180° to 210°, until the change appears to be complete. The yields obtained are as follows: *o*-nitrophenetole, above 90%; 2:4-dinitrophenetole, 56%; 6-chloro-2:4-dinitrophenetole, 0%; *p*-nitroanisole, 87%.

Contrary to the statements in the literature, pure methyl sulphate has b. p. 76°/15 mm.,  $d_{15}^{15}$  1.3348.

Contrary to statements in Beilstein's *Handbuch*, crystalline potassium methyl sulphate is anhydrous and not deliquescent.

H. W.

**Certain Bromine Derivatives of Thymol.** HANS JOST and FRIEDRICH RICHTER (*Ber.*, 1923, 56, [B], 119–123).—The action of bromine on thymol dissolved in glacial acetic acid has been examined by Dannenberg (*A.*, 1903, i, 338), who has thereby isolated a product which he considers to be the 'keto-bromide',  $\text{CMe} \begin{smallmatrix} \text{CBr} \cdots \text{CO} \\ \text{CHBr} \cdots \text{CH} \end{smallmatrix} \text{CPr}^6$ . The remarkable constitution of the compound has led the authors to re-examine the reaction; they draw the conclusion that the substance described by Dannenberg does not exist.

The action of bromine on thymol under the conditions adopted by Dannenberg proceeds beyond the formation of a dibromo-compound, and gives also a true keto-bromide,  $\text{C}_{10}\text{H}_{11}\text{OBr}_2$  (see later), which renders the product of the reaction incompletely soluble in solutions of alkali hydroxide; if a smaller proportion of bromine is used, its production is avoided and the dibromo-thymol is completely soluble; it crystallises in long, colourless prisms, m. p. +3.5–4°, b. p. 160–161°/16 mm., 175°/25 mm.

$d_{4}^{25}$  1.6631,  $d_{4}^{25}$  1.6618,  $d_{4}^{25}$  1.6588; the corresponding benzoate forms small, colourless needles, m. p. 89–90°, whereas Dannenberg gives m. p. 80–81°.

Thymol is converted by a solution of calcium bromohypobromite into tribromo-*p*-menthadienone,  $\text{CMe} \begin{smallmatrix} \text{CBr}_2 \cdot \text{CO} \\ \text{CBr} \cdot \text{CH} \end{smallmatrix} \text{CPr}^s$  or

(see above), large, dark yellow plates, m. p. 59–60° after softening at 55°. The substance decomposes somewhat readily when preserved. It liberates two atomic proportions of iodine from neutral potassium iodide solution, and is reduced by stannous chloride in the presence of hydrogen chloride and acetic acid to dibromothymol. It is converted by cold, concentrated sulphuric acid into 2:4:6-tribromo-*m*-cresol, its behaviour in this respect being similar to that of trichloro-*p*-menthadienone (Crowther and McCombie, T., 1913, 103, 539, 545). The keto-bromide is also obtained by the action of sodium hypobromite or of an excess of bromine on thymol. When dissolved in carbon tetrachloride and shaken with aqueous potassium hydroxide solution (4%), it is transformed into a brown, amorphous powder, m. p. 220–230° (decomp.) after darkening at 200°. H. W.

#### Amino-alcohols of Tetralin [Tetrahydronaphthalene].

A. GONZÁLEZ and M. CAMPOY (*Anal. Fis. Quim.*, 1922, 20, 534–538).—By the action of hypobromous acid on 1:4-dihydronaphthalene, 3-bromo-2-hydroxytetrahydronaphthalene is obtained. It is crystalline, and has m. p. 107°. By acting on it with anhydrous dimethylamine in benzene solution in a sealed tube at 120°, 2-dimethylamino-2-hydroxytetrahydronaphthalene is obtained, b. p. 65–170°/14 mm. 2-Dimethylamino-1-hydroxytetrahydronaphthalene has b. p. 157–158°/13 mm. The following compounds were also prepared: 2-benzoyl-3-dimethylaminotetrahydronaphthalene hydrochloride, m. p. 228°; 2-valeryl-3-dimethylaminotetrahydronaphthalene hydrochloride, m. p. 173°; 2-cinnamoyl-3-dimethylaminotetrahydronaphthalene hydrochloride, m. p. 178°; 2-pyruvoyl-3-dimethylaminotetrahydronaphthalene hydrochloride; 1-benzoyl-2-dimethylaminotetrahydronaphthalene hydrochloride, m. p. 176°; 1-valeryl-2-dimethylaminotetrahydronaphthalene hydrochloride, m. p. 65°; 1-cinnamoyl-2-dimethylaminotetrahydronaphthalene hydrochloride, m. p. 176.5°; 1-pyromucyl-2-dimethylaminotetrahydronaphthalene hydrochloride, m. p. 172°. Hydrochlorides of the 1:2-series are more soluble and have a lower melting point than those of the 1:3-series. G. W. R.

#### A New Class of Derivatives of $\beta$ -Naphthol, the 1-Aryl-

amino- $\beta$ -naphthols. A. WAHL and ROBERT LANTZ (*Bull. Soc. Chim.*, 1923, [iv], 33, 93–110).—Certain atoms and groups which in the benzene nucleus are only displaced at high temperatures or not at all are extremely reactive when substituted in the  $\alpha$ -position of  $\beta$ -naphthol. Thus the sulphonic group of  $\beta$ -naphthol- $\alpha$ -sulphonic acid is eliminated when the substance is treated in aqueous solution

with *p*-nitrobenzenediazonium chloride. In alkaline solution, the reaction occurs in two stages with the intermediate formation of an extremely unstable compound, which is thought to be a diazo-oxide of the formula  $\text{SO}_3\text{Na}\cdot\text{C}_{10}\text{H}_6\cdot\text{O}\cdot\text{N}\cdot\text{N}\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2$ . In presence of the least trace of acid, this yellow, water-soluble substance is instantly converted into *p*-nitraniline-red,

with liberation of sulphuric acid. With  $\alpha$ -chloro- $\beta$ -naphthol, the intermediate product cannot be isolated, the dye being produced at once with the elimination of the chlorine atom. The mobility of the halogen atom in the  $\alpha$ -position is further illustrated by the action of sodium sulphite in weak alcoholic solution,  $\beta$ -naphthol being formed and the halogen eliminated.  $\alpha$ -Chloro- or  $\alpha$ -bromo- $\beta$ -naphthol also reacts vigorously with primary aromatic amines, and, moderating the reaction by using a large excess of the amine, quantitative yields of 1-arylamino-2-hydroxynaphthalenes are obtained. 1-Anilino- $\beta$ -naphthol forms white needles, m. p. 155–156°, which darken on exposure to air. The hydrochloride forms a white, crystalline powder, and the methyl ether colourless needles m. p. 82–83°. 1-p-Toluidino- $\beta$ -naphthol forms white prisms m. p. 138–139°, and its methyl ether white needles, m. p. 94°. 1-o-Toluidino- $\beta$ -naphthol, crystallised from acetic acid, melts at 114–115°. 1-o-Anisidino- $\beta$ -naphthol crystallises in small needles, m. p. 110°. 1-o-Methoxy-m-toluidino- $\beta$ -naphthol forms white needles, m. p. 118°. 1- $\alpha$ -Naphthylamino- $\beta$ -naphthol forms grey needles, m. p. 171°, and the corresponding  $\beta$ -derivative a grey powder, m. p. 166–167°. G. F. M.

**The Influence of Boric Acid on some Polyhydroxy-derivatives of Naphthalene and Anthraquinone.** J. BÖSEKEN [with (MLLE) K. C. ANEMA and (MLLE) M. A. J. BREVET] (*Ra. trav. chim.*, 1922, 41, 778–783; cf. A., 1915, ii, 667).—Two *o*-dihydroxynaphthalenes, similarly to dihydroxyphenols (cf. Böseken and Van Rossem, A., 1912, ii, 147), considerably increase the electrical conductivity of solutions of boric acid, but the increase due to the 2:3-dihydroxy-compound is much greater than that conferred by its 1:2-isomeride. This difference is attributed to greater freedom of the hydroxyl groups in the former compound. The hydroxy-derivatives of anthraquinone were found to be insufficiently soluble in water for similar measurements of conductivity to be made, but a coloration was observed in each case on the addition of boric acid to a solution of the substance in dilute alcohol. The suggestion is made that the coloration depends on the presence of two hydroxyl groups in the ortho-position with respect to each other, or, alternatively, that it is correlated with the presence of a hydroxyl group next to a carbonyl group.

H. J. E.

**Preparation of Benzyl Esters of some Acids of High Boiling Point.** T. J. THOMPSON and GERALD J. LEUCK (*J. Amer. Chem. Soc.*, 1922, 44, 2894–2896).—Benzyl esters of certain

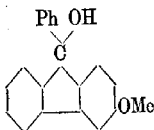

acids which boil at above 100° without decomposition have been prepared by heating together the alcohol and acid in the requisite proportions in a flask fitted with an air condenser of such a length that the benzyl alcohol vapour condenses just below its upper end, whilst it is not long enough to cause the condensation of the water vapour arising from the interaction of the alcohol and acid. Pure benzyl alcohol, free from traces of benzaldehyde, must be used. Good yields were obtained in the case of eight esters, but in two cases it was necessary to vary the pressure in the flask. Other high boiling point alcohols were tried instead of benzyl alcohol, but they did not give satisfactory results.

W. G.

**Triphenylmethyl. XXXII. *p*-Benzyloxy- and *p*-Methoxytriphenylmethyl.** M. GOMBERG and C. C. BUCHLER (*J. Amer. Chem. Soc.*, 1923, 45, 207—222).—*p*-Benzyloxytriphenylcarbinol, m. p. 94°, was prepared from the corresponding hydroxy-compound by the Schotten-Baumann reaction. When reduced with zinc and acetic acid, it yielded *p*-benzyloxytriphenylmethane, m. p. 116·5°, and with hydrogen chloride gave *p*-benzyloxytriphenylmethyl chloride, m. p. 77°, from which, by the action of sodium ethoxide, *p*-benzyloxytriphenylmethyl ethyl ether, m. p. 89°, was obtained. *p*-Benzyloxytriphenylmethyl bromide had m. p. 90°. When the chloride was shaken with molecular silver in dry benzene, *p*-benzyloxytriphenylmethyl, m. p. 142—145°, was obtained; it rapidly absorbed oxygen from the air, giving a *peroxide*, m. p. 171°, and absorbed iodine from its solution giving an unstable *iodide*. In benzene solution, the free radicle reacts with hydrogen chloride to give a mixture of the carbanyl chloride and the triarylmethane, and these interact only to a very slight extent to give a dialkyloxy-*p*-benzhydryltetraphenylmethane. A benzene solution of the free radicle exposed in a quartz tube to sunlight undergoes auto-oxidation and reduction to form a biphenylene free radicle and *p*-benzyloxytriphenylmethane. The free radicle was crystallised from a number of different types of solvents, but only in one case, namely, with ether, was an additive compound formed. The degree of dissociation of di-*p*-benzyloxyhexaphenylethane in six different solvents over a temperature range from -17° to +53° and in concentrations from 1 to 6%, was found to vary from 26 to 56% with the concentration, the temperature, and the nature of the solvent.

*p*-Methoxytriphenylcarbinol gave a chloride and a bromide, m. p. 143°, and from the chloride the free radicle *p*-methoxytriphenylmethyl, m. p. 145—150°, was obtained. It absorbs oxygen, giving a *peroxide*, m. p. 157°, and iodine, giving an *iodide*. Like the benzyloxy-compound, the main reaction with hydrogen chloride in benzene solution is to yield the carbanyl chloride and the triarylmethane. When exposed to sunlight in the same solvent a mixture of *p*-methoxytriphenylmethane and a biphenylenetriarylmethyl result, and from this solution on exposure to air 9-phenyl-3-methoxyfluorenyl *peroxide*, m. p. 200° (decomp.), was obtained. This peroxide was synthesised by a different method as follows:

3-methoxy-9-fluorenone was converted by the action of magnesium phenyl bromide into the *carbinol* (annexed formula), m. p. 84°, giving a *chloride*, m. p. 119°. From this by shaking with molecular silver the free radicle was obtained, and this on exposure to air gave the required peroxide. *p*-Methoxy-triphenylmethyl did not give any additive compounds with the various solvents tried. The degree of dissociation of di-*p*-methoxyhexaphenylethane, determined as in the case of the benzyloxy-compound, varied from 22 to 42%.

W. G.

**Triphenylmethyl. XXXI. Tautomerism of *o*-Hydroxy-triphenylcarbinol; *o*-Hydroxy- and Alkyloxy-triphenylmethyl.** M. GOMBERG and D. NISHIDA (*J. Amer. Chem. Soc.*, 1923, 45, 190—207).—When *o*-hydroxytriphenylcarbinol in solution in glacial acetic acid, carbon tetrachloride, benzene, toluene, or xylene is warmed, the solution becomes brown, the coloration beginning at 50—80°, according to the nature of the solvent, and increasing in intensity with rise in temperature or concentration of the solution. This coloration is due to tautomerisation of the carbinyl to the quinonoid form, and the change is reversible if the temperature does not exceed 110°. Above 110°, the carbinol, in solution, slowly loses water and yields, not the expected *o*-fuchsonone, but a rearrangement product, namely, 9-phenylxanthane. The carbinyl chloride undergoes similar changes, but at much lower temperatures, and loses hydrogen chloride instead of water. *o*-Benzyloxytriphenylcarbinyl chloride is considerably more stable than the *o*-hydroxy-compound, but even at ordinary temperatures it undergoes a gradual spontaneous decomposition. *o*-Hydroxy-, *o*-benzyloxy-, and *o*-methoxy-triphenylcarbinyl chlorides are all decomposed by molecular silver, giving the free radicle, but in the cases of the first two the free triarylmethyls could not be isolated owing to secondary changes, but *o*-methoxytriphenylmethyl was isolated and its physical and chemical properties were determined. It exists in solution in the unimolecular state to the extent of 26—49%, depending on the temperature. At ordinary temperatures only about one-third of the total amount of the unimolecular triarylmethyl is in the quinonoid state, the remaining two-thirds being benzenoid.

*o*-Hydroxytriphenylchloromethane was obtained by dissolving the carbinol in ether, adding calcium chloride, and saturating the solution with hydrogen chloride. Colourless crystals were obtained which rapidly became brown even in a desiccator. When shaken in benzene solution with molecular silver in the presence of air the polymerised *o*-hydroxytriphenylmethyl, m. p. 237°, was obtained together with a peroxide,  $\text{HO}\cdot\text{C}_6\text{H}_4\cdot\text{CPh}_2\cdot\text{O}\cdot\text{O}\cdot\text{CPh}_2\cdot\text{C}_6\text{H}_4\cdot\text{OH}$ , m. p. 131°. *o*-Benzyloxytriphenylcarbinol, m. p. 172°, was prepared from the hydroxy-compound, and gave the carbinyl chloride, m. p. 146°, which with molecular silver gave the polymeride, m. p. 207°, the triarylmethyl, and also a peroxide, m. p. 153°.

*o*-Methoxytriphenylcarbinol gave a stable chloride and bromide, m. p. 127—128°. The chloride when decomposed by molecular silver gave a mixture of *di-o-methoxyhexaphenylethane*, m. p. 117—121°, and *o-methoxytriphenylmethyl*. The free radicle, when exposed to air, rapidly absorbs oxygen and gives its *peroxide*, m. p. 160—161° (decomp.), and, similarly, it absorbs iodine to give its *iodide*. Both the free radicle and its chloride and bromide show decided electrical conductivity in liquid sulphur dioxide. W. G.

**Pinacolic and Semi-pinacolic Transpositions. Comparative Migratory Aptitudes of Different Radicles.** M. TIFRENEAU and (MILLÉ) J. LEVY (*Compt. rend.*, 1923, 176, 312—314).—From examples of pinacolic and semi-pinacolic transpositions of substituted glycols and iodohydrins quoted, it is shown that ethyl and benzyl groups have a much more marked aptitude for migration than has the methyl group, and in many cases the migration of the former groups is exclusive. W. G.

**Compounds containing the Trimethylene [*cyclo*Propane] Ring.** P. BRUYLANTS and A. STASSENS (*Bull. Acad. roy. Belg.*, 1921, 702—719).—*cyclo*Propanecarboxylonitrile, when prepared from  $\gamma$ -chlorobutyronitrile by distilling with dry potassium hydroxide, contains crotono- or isocrotono-nitrile. The pure *cyclo*-nitrile boils at 134—134.2°/762.5 mm. Pure *cyclo*propanecarboxylic acid has m. p. 18.1° and b. p. 181.8—182.0°/766 mm. The corresponding chloride, on chlorination, at the b. p. gives (a) 1-chlorocyclopropanecarboxyl chloride, b. p. 141—143°,  $d_4^{20}$  1.336,  $n_D^{20}$  1.4759, and (b) a small amount of what is apparently  $\alpha$ -dichlorobutyl chloride, b. p. 212—214°. The former (a) was converted by water into 1-chlorocyclopropanecarboxylic acid, colourless needles, m. p. 70—71°, b. p. 206°; sodium salt, colourless, hygroscopic needles; methyl ester, b. p. 152—153°/761 mm.,  $d_4^{20}$  1.179; ethyl ester, b. p. 65—66°/15 mm. or 162—163°/762.5 mm.,  $d_4^{20}$  1.126,  $n_D^{20}$  1.4417; amide, white crystals, m. p. 131—132°.

Ethyl 1-chlorocyclopropanecarboxylate by treatment with magnesium methyl bromide is converted into a *chlorohydrin*,  $C_3H_5Cl.CMe_2.OH$ . The latter has b. p. 156.5—157°/756 mm.,  $d_4^{20}$  1.065, forms an *acetyl* derivative,  $d_4^{20}$  1.086, and is almost unaffected by hot aqueous potassium hydroxide.

The chlorine atom in 1-chlorocyclopropanecarboxylic acid is not reactive enough to permit of the preparation of derivatives by its replacement. The constitution of the acid was decided from conductivity measurements with the acid and its sodium salt, whence the dissociation constant (100 *k*) was found to be between 0.05 and 0.06, a value only to be explained if the chloro-group is in the  $\alpha$ -position.

By treating the higher boiling fractions of the above chlorination with methyl alcohol in presence of a little sulphuric acid, methyl  $\alpha$ -chlorocyclopropanecarboxylate and methyl  $\alpha$ -dichlorobutylate, b. p. 212—214°, were obtained.

The molecular heats of combustion of *cyclo*propanecarboxylic

acid at constant volume and at constant pressure were found to be 486.1 and 486.4 cal., respectively, whereas for crotonic acid the value is 478.0 cal. The heat of formation of the acid in the liquid state is 97.8 cal. (crotonic acid, 102.3 cal.).

Determinations of the viscosities and melting points of mixtures of cyclopropanecarboxylic acid with water are described, and point to the existence of a hydrate,  $C_3H_6O_2 \cdot H_2O$ .

E. E. T.

**4-Fluoro-3-nitrobenzoic Acid.** H. ROUCHE (*Bull. Acad. roy. Belg.*, 1921, 534—547).—4-Fluorobenzoic acid, on treatment with nitric acid ( $d$  1.495), is converted to the extent of 80% into 4-fluoro-3-nitrobenzoic acid, white needles, *m. p.* 121.5°, 4-fluoronitrobenzene also being formed as the result of the displacement of the carboxyl group by the nitro-group. The new acid forms soluble and highly coloured salts (alkali metals, red; alkaline-earth metals, yellow or orange). The silver salt is unstable. The ethyl ester, yellow crystals, melts at 45.3°. The chloride, *b. p.* 210°/130 mm., on treatment with aqueous ammonia, gives 3-nitro-4-aminobenzamide, dry ammonia in ethereal solution, however, giving 4-fluoro-3-nitrobenzamide, a waxy mass, *m. p.* 153°.

The solubilities of 4-fluoro-, 4-chloro-, and 4-bromo-3-nitrobenzoic acids have been compared.

The dissociation constants (100 *k*) of 4-fluoro- and 4-chloro-3-nitrobenzoic acids were found to be respectively 0.0433 and 0.048 (cf. A., 1890, 1209), the corresponding 4-bromo-acid being stronger than these two acids. *p*-Fluorobenzoic acid, used in comparison, gave 100 *k* 0.00735. Owing to the labile nature of the fluoro-group in fluoronitrobenzoic acid, conductivity determinations with the latter were carried out in presence of hydrochloric acid.

A study of the velocities of reaction with sodium methoxide of sodium fluoronitrobenzoate and *o*-fluoronitrobenzene showed that the carboxyl group renders a para-fluoro-group more labile.

E. E. T.

#### **$\alpha$ -Nitrophenylacetamide and some of its Derivatives.**

A. J. VAN PESKI (*Rec. trav. chim.*, 1922, 41, 687—700; cf. A., 1909, i, 647).—On treatment of  $\alpha$ -isonitrophenylacetamide with concentrated sodium hydroxide solution, the sodium derivative of the amide which is first formed gradually disappears and sodium nitrophenylacetamide is formed. This reacts with bromine to give  $\alpha$ -bromo- $\alpha$ -nitrophenylacetamide, which is easily obtained pure. The action of dilute sulphuric acid on the aqueous solution of the sodium derivative gives a white precipitate which becomes viscid and then solidifies. This consists of  $\alpha$ -nitrophenylacetamide, which on crystallisation from benzene or chloroform is obtained in the form of white needles, *m. p.* 82.5—83°. These remain unchanged for a considerable time; decomposition may be detected by a lowering of the melting point, and after some months the substance is transformed into a thick brown syrup. Complete decomposition may be effected in less than two hours by heating

on the water-bath : among the decomposition products are nitro-gen, nitrous oxide, phenylglyoxylic acid, phenylglyoxylamide, benzonitrile, water, and two unidentified derivatives of phenylglyoxylamide. On boiling in contact with water, the products are phenylglyoxylic acid and its amide, benzoic acid and the oxime of phenylglyoxylamide. The chloro-derivative of  $\alpha$ -nitrophenylacetamide is prepared in a similar manner to the bromo-derivative, but the corresponding iodine compound is obtained in ethereal solution of iodine by reaction with the silver salt of the amide. All three halogen derivatives liberate nitric oxide and the halogen on being heated; the decomposition may take place explosively. The following descriptions are given :  $\alpha$ -chloro- $\alpha$ -nitrophenylacetamide, white prisms, m. p. 107–115°;  $\alpha$ -bromo- $\alpha$ -nitrophenylacetamide, crystals, m. p. 108–116°;  $\alpha$ -iodo- $\alpha$ -nitrophenylacetamide, yellow, rod-shaped crystals, m. p. 97–100°; *o*-bromo- $\alpha$ -nitrophenylacetamide, white, rod-shaped crystals, m. p. 125°; *p*-bromo- $\alpha$ -nitrophenylacetamide, white, rod-shaped crystals, m. p. 101.5°; ethyl imidophenylperacetate,  $\text{CH}_2\text{Ph}\cdot\text{C}(\text{NH})\cdot\text{O}\cdot\text{OEt}$ , small, rod-shaped crystals, m. p. 180°.

H. J. E.

**Asymmetrical Synthesis.** EMIL ERLÉNMEYER and HANS ERLÉNMEYER (*Biochem. Z.*, 1922, **133**, 52–62).—If bromine be added to a solution containing cinnamic acid, a sugar, and a zinc salt, the dibromophenylpropionic acid formed is optically active, except in the case of lactose, where the resulting acid is inactive. Presumably a complex salt of zinc with cinnamic acid on the one hand, and with the sugar on the other, is formed, and this optically active compound adds on bromine asymmetrically. With dextrose, levulose, and sucrose excess of the  $l$ - $\alpha\beta$ -dibromo- $\beta$ -phenylpropionic acid is formed, and with *l*-arabinose excess of the *d*-acid. Levulose is particularly effective, and it is likewise active if  $\alpha$ -methylcinnamic acid is used instead of cinnamic acid.

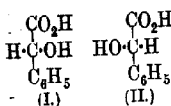

W. O. K.

**The Iodination of *m*-Hydroxybenzoic Acid.** P. H. BEIJER (*Rec. trav. chim.*, 1922, **41**, 701–702).—Monoiodohydroxybenzoic acid was prepared by Wieselsky's method (*Annalen*, 1874, **174**, 405). An identical acid was obtained from 4-nitro-3-hydroxybenzoic acid by reduction of the nitro-group, diazotisation, and treatment with potassium iodide. The acid is thus 4-iodo-3-hydroxybenzoic acid, so that the action of iodine yields a derivative substituted similarly to that obtained on bromination. This was confirmed by the preparation of 6-iodo-3-hydroxybenzoic acid cf. Lüppricht, A., 1891, 1036) which is not identical with the acid obtained by Wieselsky.

H. J. E.

**The Configuration of Mandelic Acid and other  $\alpha$ -Hydroxyacids.** KARL FREUDENBERG, FRITZ BRAUNS, and HEINRICH ENGEL (*Ber.*, 1923, **56**, [B], 193–200).—The hypothesis that the optical activity of similarly constituted substances of the same configuration is influenced in a uniform manner by change of temperature, dilution, or addition of neutral salts has led Clough

(T., 1918, 113, 526) to assign *l*-mandelic acid to the *d*-series (configuration I), whereas Hudson (A., 1918, i, 292), on the consideration that all hydroxy-acids which yield dextrorotatory amides and hydrazides belong to the *d*-series, has assigned to it the configuration II (*l*-mandelic acid is levorotatory). *l*-Hexahydromandel-

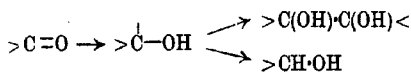

amide has now been prepared, and shown to be strongly dextro-rotatory. Since, therefore, *l*-mandelic and *l*-hexahydromandelic acids are configurationally related, Hudson's rule appears to be broken. A consideration of the optical activities of  $\alpha$ -hydroxy-acids of known configuration and of their amides confirms the validity of Clough's deductions. Hudson's rule appears merely to require a slight modification in the sense that  $\alpha$ -hydroxy-acids are considered to belong to the *d*-series when their specific rotation is displaced in the dextro-direction on conversion into the amide. An actual transition from *l*avo to dextro is only observed with substances of low rotatory power, such as the monocarboxylic acids of the sugar group, from a study of which the rule was first developed.

*dl*-cycloHexylglycollic acid, m. p. 134—135° [Godehot (A., 1910, i, 480) gives 130—131°], is prepared by the catalytic hydrogenation of *dl*-mandelic acid in aqueous solution in the presence of platinum with gum arabic or gelatin as protective colloid. It is smoothly esterified to *methyl dl*-cyclohexylglycolate, b. p. 122—123°/18 mm., from which the corresponding amide, m. p. 156° (Godehot gives m. p. 155°) is prepared. *dl*-cycloHexylglycolphenylhydrazide has m. p. 213°. *d*(-)-cycloHexylglycollic acid, prepared by hydrogenation of *l*-mandelic acid, has m. p. 128—129°,  $[\alpha]_{\text{D}}^{25}$  yellow -26.6°,  $[\alpha]_{\text{D}}^{25}$  yellow -25.8° in glacial acetic acid solution. The corresponding *methyl* ester has b. p. 123°/19 mm.,  $[\alpha]_{\text{D}}^{25}$  yellow -4.7°; the *phenylhydrazide*, m. p. about 215° (decomp.),  $[\alpha]_{\text{D}}^{25}$  yellow +55.25° in glacial acetic acid, and the *amide*, m. p. 158°,  $[\alpha]_{\text{D}}^{25}$  yellow +47.4° in alcohol,  $[\alpha]_{\text{D}}^{25}$  yellow +41.16° in aqueous (20%) alcohol are described.

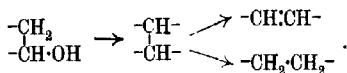

*d*(-)-Lactic acid, prepared by the resolution of the *r*-acid with morphine (cf. Irvine, T., 1906, 89, 935), is converted into the *methyl* ester, b. p. 50—60°/25 mm.,  $[\alpha]_{\text{D}}^{20}$  yellow +7.3°, and thence into the *amide*, m. p. 49—51°,  $[\alpha]_{\text{D}}^{25}$  yellow +22.2°; it is remarkable that the active amide is very deliquescent and that this property is not shared by the *r*-amide. H. W.

**The Theory of Reduction. The Reduction of the Carbonyl Group by Zinc Amalgam.** WILHELM STEINKOPF and ARTHUR WOLFRAM (*Annalen*, 1923, 430, 113—161).—A careful study of the action of zinc amalgam and aqueous or alcoholic hydrochloric acid on a variety of carbonyl compounds has shown that product of several distinct types may be obtained, and that the formation of these may be accounted for by ascribing to the process the following general mechanism. In the first place, hydrogen becomes attached to the oxygen of the carbonyl group, giving a radical (containing trivalent carbon) which may react either with

itself, yielding a pinacone or with more hydrogen, forming an alcohol :

secondly, if the alcohol contains a  $CH_2$  residue next to the carbinol group, water may be eliminated, giving first a compound containing two tervalent carbon atoms, and ultimately either a saturated or unsaturated substance :

Stress is laid on the view that the formation of the saturated and unsaturated substances is simultaneous and not successive, at least in the main. The constitution of the original carbonyl compound and the conditions of the reduction may determine which of the above four side reactions takes place preferentially, but the above mechanism is considered to be generally applicable.

Benzophenone, on reduction with zinc amalgam and aqueous hydrochloric acid, yields benzpinacone and traces of diphenylmethane; by reduction in alcoholic solution, tetraphenylethylene,  $\alpha$ - and  $\beta$ -benzpinacolin, and diphenylmethane may be obtained. Benzhydrol on reduction in alcoholic solution gives diphenylmethane, and the benzpinacolins give tetraphenylethylene.

Ethyl acetoacetate, on reduction in alcohol, gives ethyl crotonate and ethyl butyrate. Ethyl crotonate is not reduced to ethyl butyrate under similar conditions.

Ethyl laevulate yields ethyl valerate and an unsaturated ester, probably  $\beta$ -ethylidenepropionic ester.

Ethyl benzoylacetate on reduction in alcohol with amalgamated zinc yields  $\beta$ -diphenylpentadilactone (A., 1912, i, 889), ethyl  $\beta$ -phenylpropionate, and an oil, b. p.  $210-213^\circ/ < 1$  mm. Using amalgamated zinc, the products are the dilactone, ethyl cinnamate, ethyl  $\beta$ -phenylpropionate,  $\beta$ -diphenyl- $\Delta^2$ -crotonolactone- $\gamma$ -acetic acid, and probably *meso*- $\beta\beta'$ -dihydroxy- $\beta\beta'$ -diphenyladipic acid. Ethyl cinnamate on reduction with amalgamated zinc in alcoholic hydrogen chloride gives ethyl  $\beta$ -phenylpropionate.

Ethyl phenylglyoxylate gives ethyl mandelate and ethyl diphenyltartrate, and phenylglyoxylic acid yields mandelic acid.

Reduction of acetophenone in aqueous solution leads to ethyl benzene, acetophenonepinacolin, and styrene and its polymerisation products, along with small amounts of acetophenonepinacone, and  $\gamma$ -diphenylbutane (?). In alcoholic solution, the products are styrene and its polymerides, acetophenonepinacone and  $\alpha$ -chloroethylbenzene.

The products of reduction of benzaldehyde in aqueous solution are toluene, benzyl alcohol, stilbene, and hydrobenzoin. The action of zinc chloride on benzyl alcohol gives rise to stilbene hydrochloride.

C. K. I.

**The Isomeric Esters of Benzoylacrylic Acid.** GRACE POTTER RICE (*J. Amer. Chem. Soc.*, 1923, 45, 222—238).—The yellow methyl benzoylacrylate, obtained by Kozniewski and Marchlewski (cf. A., 1906, i, 759) can be converted into a colourless *stereo-isomeride*, m. p. 67°, by exposure to sunlight. The reverse change occurs if the colourless isomeride is exposed to sunlight in a solution containing a trace of iodine or bromine. Both the esters behave alike on oxidation by potassium permanganate in cold acetone solution, and they give the same product on treatment with nitromethane. Their behaviour towards alkaline reagents is not, however, the same. On boiling the yellow ester with dilute sodium carbonate solution, almost complete decomposition takes place, and it is not possible to isolate any benzoylacrylic acid. The colourless ester, under similar conditions, gives a 60% yield of benzoylacrylic acid. With concentrated hydrochloric acid, both the esters give a mixture of benzoylacrylic and  $\alpha$ -hydroxybenzoylpropionic acids. The benzoylacrylic acid obtained in either of these cases corresponds, in configuration, with the yellow ester.

The colourless ester reacts with two molecules of semicarbazide hydrochloride to give the *semicarbazone* of methyl  $\alpha$ -semicarbazidobenzoylpropionate, m. p. 177—178°. If, however, only one molecule of semicarbazide is used then the product is methyl  $\alpha$ -semicarbazidobenzoylpropionate, m. p. 150—150.5°, which when treated in cold acid solution with sodium nitrite gives methyl nitroso- $\alpha$ -semicarbazidobenzoylpropionate, m. p. 125°. With one molecule of semicarbazide the yellow ester gives the same product as the colourless ester, but with two molecules it yields methyl  $\alpha$ -semicarbazido-3-phenylpyrazolone-4-acetate, m. p. 172°, which when decomposed by hydrochloric acid gives the methyl semicarbazidobenzoylpropionate described above.

Ethyl benzoylacrylate was obtained in a yellow form, b. p. 184—185°/25 mm., and in a colourless form, m. p. 54°. As in the case of the methyl esters, the following products were prepared: the *semicarbazone* of ethyl  $\alpha$ -semicarbazidobenzoylpropionate, m. p. 187°; ethyl  $\alpha$ -semicarbazidobenzoylpropionate, m. p. 151—152°; ethyl nitroso- $\alpha$ -semicarbazidobenzoylpropionate, m. p. 127°; ethyl  $\alpha$ -semicarbazido-3-phenylpyrazolone-4-acetate, m. p. 171°.

Benzoylacrylic acid reacts with semicarbazide, and gives the same products whether one or two molecules of the latter are used, namely, two isomeric *semicarbazones*, m. p. 205° and 225°, respectively, and a *hydrate* of the former, m. p. 190°. All three compounds react with bromine as unsaturated compounds and two atoms of bromine are added on to the molecule, and a compound, m. p. 171°, is obtained. W. G.

**Dyes derived from Diphenic Anhydride.** SIKHIBHUSHAN DUTT (T., 1923, 423, 225—228).

**The Action of Bromine on Methylcoumaric and Methylcoumarinic Acids.** EINAR BILLMANN and HAKON LUND (*Ann. Chim.*, 1922, [ix], 18, 263—282).—The addition of bromine in anhydrous solution to methylcoumaric and methylcoumarinic

acids apparently results in the formation of a single product (cf. Fittig and Ebert, A., 1883, 474; Werner, A., 1906, i, 180), but Perkin (T., 1881, 39, 420) and Stoermer and Friemel (A., 1911, i, 632) have obtained indications of two acids resulting. The last-named workers isolated an acid, m. p. 170°; the authors' work confirms the formation of this single compound, but they were unable to determine its constitution with certainty, although the substance is presumed to be  $\alpha\beta$ -dibromo- $\beta$ -methoxyphenylpropionic acid. This acid on treatment with powdered zinc was converted into methylcoumaric acid, whilst water readily effected its hydrolysis into  $\alpha$ -bromo- $\beta$ -hydroxy- $\beta$ -methoxyphenylpropionic acid, crystals, m. p. 134°, which yields on dehydration  $\alpha$ -bromo- $\beta$ -methoxyphenylacrylic acid, obtained directly from  $\alpha\beta$ -dibromo- $\beta$ -methoxyphenylpropionic acid by Perkin (*loc. cit.*). The hydrolysis by which the acid was obtained must not be effected at a high temperature, otherwise carbon dioxide is evolved with formation of *methoxybromostyrene*, a light yellow oil, b. p. 142—143°/14—16 mm., whilst hydrobromic acid in acetic acid solution reverses the hydrolysis. Treatment of the acid with zinc powder results in the formation of methylcoumaric acid. The last-named substance yields on bromination by means of solution of bromine in aqueous potassium bromide,  $\alpha\beta$ -5-tribromo- $\beta$ -methoxy-5-phenylpropionic acid, which was also obtained from  $\alpha\beta$ -dibromo- $\beta$ -methoxyphenylpropionic acid and bromine water, and also by the action of hydrobromic acid on  $\alpha$ -5-dibromo- $\beta$ -hydroxy- $\beta$ -methoxyphenylpropionic acid. The latter was prepared by the action of bromine water on  $\alpha$ -bromo- $\beta$ -hydroxy- $\beta$ -methoxyphenylpropionic acid and forms crystals, m. p. 137°, isomeric with and transformed by heating into an acid of m. p. 155° identical with that prepared by Read and Andrews (T., 1921, 119, 1782). This acid may also be obtained by hydrolysis of  $\alpha\beta$ -5-tribromo- $\beta$ -methoxyphenylpropionic acid, the reaction being reversed by hydrobromic acid. Mercuric acetate and methylcoumarinic acid combine to form a mercuric compound (cf. A., 1900, i, 431). This was not isolated, but was used as an intermediate in the preparation of  $\beta$ -hydroxy- $\beta$ -methoxyphenylpropionic acid, which resulted from the elimination of the mercury by means of hydrogen sulphide. This acid has m. p. 88.5° and is quantitatively converted into methylcoumaric acid when boiled with dilute sulphuric acid, whilst bromine water yields a ring-substituted derivative, 5-bromo- $\beta$ -hydroxy- $\beta$ -methoxyphenylpropionic acid, m. p. 108°. All the ring-substituted bromo-compounds dealt with are converted on oxidation with permanganate into 2-methoxy-5-bromobenzoic acid, and the same substance was obtained by oxidation of methylcoumaric acid with permanganate and subsequent treatment of the methoxybenzoic acid so formed with bromine water.

H. J. E.

The Chemistry of the Glutaconic Acids. XIV. Three-carbon Tautomerism in the *cycloPropane* Series. FRANK ROBERT GOSS, CHRISTOPHER KELK INGOID, and JOCELYN FIELD THORPE (T., 1923, 123, 327—361).

**The Thermal Decomposition of certain Hydroaromatic Dicarboxylic Acids.** A. WINDAUS, W. HÜCKEL, and G. REVERBY (*Ber.*, 1923, 56, [B], 91—98).—Blanc's rule (A., 1907, i, 710), according to which pimelic and adipic acids are converted into cyclic ketones when heated at about 300° (in the presence of acetic anhydride if necessary), whereas glutaric and succinic acids give internal anhydrides under similar conditions, appears to be generally applicable in the aliphatic series. An experimental examination of the possibility of applying it in the hydroaromatic series has been undertaken, and the behaviour of certain hydroaromatic *o*-dicarboxylic acids is now described.

*cis*-cyclo-Hexane-1:2-dicarboxylic anhydride is decomposed at 380° into carbon dioxide, water, anthraquinone, and various hydrogenated derivatives of anthracene; its behaviour is thus similar to that of calcium succinate.

Homophthalic [*o*-carboxyphenylacetic] acid is smoothly hydrogenated in glacial acetic acid solution in the presence of platinum black to a mixture of *cis*- and *trans*-*o*-carboxycyclohexanecarboxylic acids from which the pure *cis*-acid is isolated by fractional crystallisation; it forms aggregates of prisms, m. p. 146°, and is converted by acetic anhydride into the corresponding *anhydride*, rectangular plates, m. p. 57°. The *cis*-acid is isomerised by hydrochloric acid at 200° to the *trans*-acid, colourless crystals, m. p. 157° (*anhydride*, short needles, m. p. 80—81°). When either *anhydride* is heated for a considerable time at 220°, an equilibrium mixture containing about 25% of the *cis*- and 75% of the *trans*-variety is produced.

*o*-Carboxyphenylpropionic acid is catalytically hydrogenated to *cis*-*o*-carboxycyclohexanepropionic acid, prisms, m. p. 103°; the calcium salt and the *di-anilide*, lustrous leaflets, m. p. 159°, are described. The acid is isomerised by concentrated hydrochloric acid at 180° to *trans*-*o*-carboxycyclohexanepropionic acid, prisms, m. p. 143°. The corresponding *di-anilide*, m. p. 212°, is prepared from the acid and aniline or by heating the *cis*-*di-anilide* at 250°; it can be distilled unchanged in a high vacuum. The *cis*- or the *trans*-acid is not converted into an alicyclic ketone containing one less atom of carbon when heated alone, but either acid is transformed by distillation with acetic anhydride into *hexahydro- $\alpha$ -hydrindone*,  $C_8H_{10} \begin{smallmatrix} \text{CH}_2 \\ \diagup \quad \diagdown \\ \text{CO} \end{smallmatrix} \text{CH}_2$ , a colourless liquid, b. p. 216°/758 mm.,  $d_4^{20}$  0.9982,  $n_D^{20}$  1.47915,  $n_D^{25}$  1.48117,  $n_D^{30}$  1.48827,  $n_D^{35}$  1.49342. The corresponding *semicarbazone* crystallises in needles, m. p. 214—215° (decomp.) when rapidly heated; the *oxime*, lustrous needles, m. p. 79—80°, is described. H. W.

**Total Hydrogenation of Naphthalic [Naphthalene-1:8-dicarboxylic] Acid.** J. CASARES and J. RANEDO (*Anal. Fis. Quim.*, 1922, 20, 519—526).—Naphthalene-1:8-dicarboxylic acid was hydrogenated to the tetrahydro- and decahydro-acids by the action of hydrogen in the presence of platinum. Specially purified reagents were used, and repeated activations were necessary.

The decahydronaphthalene-1:8-dicarboxylic acid thus obtained has no definite melting point, and is probably a mixture of *cis*- and *trans*-isomerides. Hydrogenation was effected more easily and without activations by use of the methyl and ethyl esters of naphthalic acid. Methyl tetrahydronaphthalene-1:8-dicarboxylate thus obtained from methyl naphthalate forms crystals, m. p. 74°. Ethyl tetrahydronaphthalene-1:8-dicarboxylate forms crystals, m. p. 52°, and has b. p. 193°/17 mm. Methyl decahydronaphthalene-1:8-dicarboxylate forms crystals, m. p. 103—105°. G. W. R.

**The Preparation of Benzenepentacarboxylic Acid.** KARL FLEISCHER and EWALD RETZE (*Ber.*, 1923, 56, [B], 228—234).—A new method of preparing benzenepentacarboxylic acid (cf. Fleischer and Siefert, A., 1920, i, 621), which starts from tetrahydronaphthalene, is described.

2-Ethyl-5:6:7:8-tetrahydronaphthalene condenses with diethyl-malonyl chloride in the presence of aluminium chloride and carbon disulphide to yield 2:2:4-triethyltetrahydronaphth- $\alpha\beta$ -indane-1:3-dione (annexed formula), colourless crystals, m. p. 39°. The substance is oxidised by nitric acid at 125—150° to 2:2-dicthyliindane-1:3-dione-4:5:7-tricarboxylic acid, colourless crystals, m. p. 249° (decomp.) after slight previous softening; when more drastically treated with nitric acid, it gives benzenepentacarboxylic acid, m. p. 232—233°.

2:2:4-Triethyltetrahydronaphth- $\alpha\beta$ -hydrindene, a colourless liquid, b. p. 203—205°/19 mm.,  $d_4^{20}$  0.9673,  $n_D^{20}$  1.5352, is isolated from the products of the action of amalgamated zinc and hydrochloric acid on 2:2:4-triethyltetrahydronaphth- $\alpha\beta$ -indane-1:3-dione. It condenses with acetyl chloride in the presence of aluminium chloride and carbon disulphide to yield 5-acetyl-2:2:4-triethyltetrahydronaphth- $\alpha\beta$ -hydrindene, colourless needles, m. p. 66° after softening at 63°, which, with *p*-nitrobenzaldehyde and potassium hydroxide solution, gives the corresponding *p*-nitrobenzylidene derivative,  $C_{28}H_{35}O_3N$ , canary-yellow needles, m. p. 161.5°. The acetyl compound is reduced by zinc and hydrochloric acid to 2:2:4:5-tetraethyltetrahydronaphth- $\alpha\beta$ -hydrindene, a pale yellow, very viscous liquid, b. p. 220—222°/20 mm.,  $d_4^{27}$  0.9647,  $n_D^{27}$  1.5365.

H. W.

**Dicyclic and Polycyclic Compounds with Bridged Linking.**  
*dicyclo*-[1,3,3]-Nonane and its Derivatives. HANS MEERWEIN [with FRANZ KIEL, GUSTAV KLÖSGEN, and EDWIN SCHOCH] (*J. pr. Chem.*, 1922, [ii], 104, 161—206; cf. A., 1913, i, 869).—*dicyclo*-[1,3,3]-Nonan-2:6-dione, the preparation of which has now been slightly improved, has been further characterised by the formation of the unsaturated diacetyl derivative of the dienol form, colourless needles, m. p. 78—79°. When the *disemicarbazone*, a white, crystalline powder, m. p. 226°, is heated for six hours at 230° with 10% ethyl-alcoholic sodium ethoxide solution (cf. Wolff,

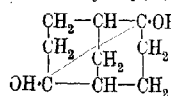

A., 1912, i, 988), dicyclononane (annexed formula), snow-white, feathery, plastic crystals, m. p. 145–146°, b. p. 168.5–170°, may be isolated from the product in 40% yield by distillation in steam. Reduction of the dicyclononandione with sodium amalgam gives a mixture of a tri-cyclononandiol (see below) and trans-dicyclo-

[1,3,3]-nonan-2:6-diol, m. p. 219°, which gives a reddish-violet coloration with alcohol and sulphuric acid, and a sapphire-blue coloration with acetic anhydride and sulphuric acid. The diacetate, m. p. 35°, b. p. 173–174°/17 mm., and the dibenzoate, glistening, white leaflets, m. p. 96–97°, are described. On oxidation with chromic acid, the dicyclo-glycol is reconverted into the diketone. When dehydrated with sulphuric acid, it gives dicyclo-[1,3,3]- $\Delta^6$ -nonen-2-ol, m. p. 133°, b. p. 224–226°, which has an intense camphor-like odour, is plastic, gives the same colour reactions as the dicyclo-glycol, and forms a liquid acetate, b. p. 111–112°/12 mm., having an intense odour resembling that of pine needles. This unsaturated alcohol, when reduced by means of hydrogen and platinum black, gives an 88% yield of dicyclo-[1,3,3]-nonan-2-ol, colourless crystals, m. p. 185°, which forms a liquid acetate, b. p. 128°/20 mm., and is oxidised by chromic acid mixture to dicyclo-[1,3,3]-nonan-2-one, plastic, colourless crystals, m. p. 150°; the ketone is characterised by the semicarbazone, colourless, needle-shaped crystals, m. p. 180–181°, the benzylidene derivative, m. p. 127–128°, which dissolves in concentrated sulphuric acid with a lemon-yellow coloration, and the cinnamylidene derivative, yellow needles, m. p. 116–117°, which similarly gives an orange-red coloration. Attempts to eliminate two molecules of water from the dicyclo-glycol have led only to resinous products, probably because the second double bond appears in the 5:6, and not the 6:7, position, the resulting hydrocarbon then isomerising to cyclooctatetrene, which is well known to polymerise easily.

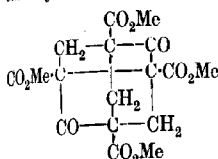

As mentioned above, the reduction of the dicyclo-diketone leads also to tricyclo-[1,3<sup>2</sup>,3<sup>2</sup>,0]-nonan-2:6-diol (annexed formula), which

may most readily be obtained by using the crude reduction product for the preparation of the dicyclononanol, it being then isolated from the sulphuric acid residue after the unsaturated alcohol has been removed in a current of steam. It forms glistening needles, m. p. 141°, is appreciably volatile in steam, dissolves without any coloration in concentrated sulphuric acid, and is oxidised by chromic acid in glacial acetic acid solution to the original dicyclo-diketone. The diacetate, tabular crystals, m. p. 121°, the dibenzoate, needles, m. p. 153–154°, and the diphenylurethane, fine needles, m. p. 201°, are described.

Methyl dicyclo-[1,3,3]-nonan-2:6-dione.1:3:5:7-tetracarboxylate forms with sodium methoxide (1 mol.) a white, crystalline monosodium derivative, which is decomposed by water into the free ester (1 mol.) and the disodium derivative (1 mol.); the latter, which

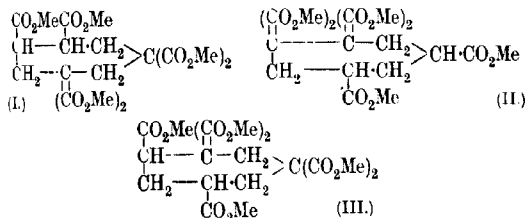

is directly produced from the ester and sodium methoxide (2 mols.), is a colourless, crystalline, hygroscopic powder, dissolving in water with opalescence. The action of bromine (2 atoms) on the monosodium derivative gives *methyl 3-bromodicyclo-[1,3,3]-nonan-2:6-dione-1:3:5:7-tetracarboxylate*, rhombohedra, m. p. 154°, which is soluble in dilute alkalis and gives a reddish-violet coloration with ferric chloride. *Methyl 3:7-dibromodicyclo-[1,3,3]-nonan-2:6-dione-1:3:5:7-tetracarboxylate*, colourless prisms, which is formed from the above-mentioned disodium derivative and bromine (5 atoms), is insoluble in alkalis, does not give a coloration with ferric chloride, and melts at 142° with elimination of bromine, giving *methyl tricyclo-[1,3,3',0]-nonan-2:6-dione-1:3:5:7-tetracarboxylate* (annexed formula), colourless prisms from xylene and

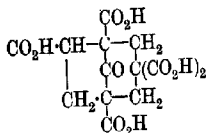

glacial acetic acid, leaflets from amyl-alcohol, m. p. 247—248°. The same compound is produced by the action of sodium and zinc dust in xylene solution on the dibromo-ester, by the action of bromine on the disodium derivative, or by the thermal decomposition of the *copper* compound of

the *dicyclo-tetracarboxylic* ester (A., 1913, i, 869), but is most readily prepared by treating the monobromo-ester with sodium methoxide (1 mol.), care being taken to avoid excess of alkali during the reaction. The tricyclic ester undergoes fission with methyl-alcoholic sodium methoxide, two molecules of methyl alcohol being taken up, with formation of a *methyl cycloheptanhexacarboxylate*, white needles from amyl alcohol, large prisms from methyl or ethyl alcohol, m. p. 128°, which must have one of the formulæ (I), (II), or (III), according as fission occurs in the positions 2:3 and 6:7, 1:2

and 5:6, or 1:2 and 6:7, respectively. The corresponding *cycloheptanhexacarboxylic acid*, obtained by hydrolysing the ester with aqueous barium hydroxide, separates from glacial acetic acid or anhydrous formic acid as a microcrystalline powder, m. p. 177° (decomp.), and loses carbon dioxide when heated with water and a trace of hydrochloric acid, giving *cycloheptane-1:3:5:6-tetracarboxylic acid*, m. p. 233°, which is probably a mixture of several of the five possible stereoisomeric forms, and may be derived equally well from any of the three possible hexacarbomethoxy-esters. Alternate formulæ are suggested for the *dianhydride*, m. p.

197—198°. When the *tricyclo*-ester is heated with aqueous barium hydroxide, hydrolytic fission of the bond 2 : 3(?) occurs, with formation of dicyclo-[1,2,3]-*octan-8-one-pentacarboxylic acid* (probable formula annexed), beautiful transparent prisms, which melt at 184—185° with evolution of carbon dioxide, but not of water.

Oxidation of the *dicyclononenol* (above) with chromic anhydride in glacial acetic acid solution gives dicyclo-[1,3,3]- $\Delta^6$ -*nonen-2-one*, a white, plastic mass, of camphor-like odour, m. p. 82°, b. p. 213—217°; it forms a *semicarbazone*, star-shaped clusters of needles, m. p. 190.5—191°, and a *cinnamylidene* derivative, yellow needles, m. p. 117°, which dissolves in concentrated sulphuric acid with an orange-red coloration. By the reduction of the dioxime of the *dicyclononandione* (A., 1913, i, 869) by means of sodium and *dicyclononandione* is produced as a alcohol, *trans-2 : 6-diaminodicyclo-[1,3,3]-nonane* is produced as a transparent, crystalline, hygroscopic mass, b. p. 125—130/14 mm., which has a strong odour characteristic of bases and rapidly liquefies in contact with the air. The dihydrochloride, colourless, non-hygroscopic, crystalline powder, the *diacetyl* derivative, glistening clusters of needles, m. p. 214°, and the *dibenzoyl* derivative, indefinite crystals, m. p. 351°, are described. Distillation of the dihydrochloride gives 2-aminodicyclo-[1,3,3]- $\Delta^6$ -*nonene*, a colourless, translucent, crystalline mass, m. p. 37.5°, b. p. 104°/17 mm., which rapidly liquefies on exposure to the air, possesses a strong odour reminiscent of both conine and nicotine, and is immediately oxidised by potassium permanganate in sulphuric acid solution.

Space formulae are used to indicate the absence of strain, not only in dicyclo-[1,3,3]-*nonane* itself, but also in the *tricyclopinacene*, the 2 : 6 bridge-bond of which is opened and closed with extraordinary ease, and in the *tricyclo-tetracarboxylic ester*, the production of which by the thermal elimination of free bromine provides an entirely new type of ring formation. Since the *dicyclononandionetetracarboxylic ester* is nearly "spannungslos," the ready formation by the action of sodium methoxide of a *cycloheptane* ring is taken to indicate that the latter is also free from strain, and therefore probably lies in more than one plane.

The stability of the *dicyclononandionetetracarboxylic ester*, and the ready fission of the *tricyclo*-ester, with alkaline reagents, are ascribed to the presence in the former, but not in the latter, of hydrogen attached to the ring-atoms 3 and 7 (cf. Dieckmann, A., 1901, i, 539).

A similarity is indicated between the physical properties of the *dicyclononane* derivatives and compounds of the camphor series; this does not, however, extend to the physiological properties, examples of which, contributed by Schüller, are quoted.

W. S. N.

**Cryoscopic Investigations on the Capacity to form Schiff's Bases.** BERNARDO ODDO and FRANCESCO TOGNACCHINI (*Gazzetta*, 1922, 52, ii, 347—361).—The method previously used (A., 1913, i,

1233; 1915, ii, 414, 415, and this vol., i, 255) has now been applied to the investigation of the course of the reaction between aniline and a number of aliphatic and aromatic aldehydes and ketones. The molecular weight, calculated from the depression of the freezing point of the aniline, is expressed as a percentage of the theoretical value for the aldehyde or ketone taken, and the result plotted as a function of the time.

Like all aromatic aldehydes, *p*-tolualdehyde reacts promptly with aniline, whereas phenylacetaldehyde reacts decidedly more slowly; with cinnamaldehyde, the reaction takes place more easily. As in the reaction with phenylhydrazine, anisaldehyde reacts with aniline far more rapidly than does vanillin, the hydroxyl group apparently exerting a retarding effect; a similar effect is exercised by a nitro-group in the meta-position to the aldehyde group. Anisaldehyde, cuminaldehyde, *p*-nitrobenzaldehyde, and *p*-tolualdehyde, all of which are substituted in the para-position, exhibit similar molecular weight-time curves.

The reaction is relatively slow with aromatic, and more rapid with aliphatic, ketones, mixed ketones showing intermediate behaviour. The results given by benzil, acetylacetone, and acetonylacetone show that the reactivity increases with the degree of separation of the two carbonyl groups; with benzil, however, it is doubtful if the reaction proceeds in the direction of the formation of the Schiff's base. Further, it seems that only one carbonyl group reacts in the case of  $\beta$ -diketones, whereas both carbonyl groups of the  $\gamma$ -diketones react. With acetylacetone and acetonylacetone, the experimental conditions, and with the former also the results obtained, preclude the formation of heterocyclic nuclei.

Camphor reacts not at all with aniline, and menthone and carvone only slowly. As regards the cyclohexane ketones, the reaction is slowest with the ortho- and most rapid with the para-substituted compounds, cyclohexanone occupying an intermediate position. Phenanthraquinone and santonin react slowly and phenolphthalein instantaneously, the stage reached in ten minutes persisting unchanged for twenty-one hours.

T. H. P.

**Preparation of  $\alpha$ -Homopiperonal from Safrole by the Action of Ozone, and Synthesis of its Derived Perfumes. I.** SHŌCHIRŌ NAGAI (*J. Chem. Ind. Japan*, 1922, 25, 1409—1421; cf. S. Nagai, *ibid.*, 1922, 25, 631).—By passing about 36 litres per hour of air containing 2—3% of ozone into a glacial acetic acid (10—15 parts) solution of safrole (1 part) at the ordinary temperature, safrole ozonide is produced readily. The ozonide is, however, liable to decompose spontaneously even at the ordinary temperature when freed from the solvent, or when heated, and is also readily polymerised into resinous matter by the effect of heat, air, alkali, etc. If the ozonide is decomposed by adding gradually water and zinc powder to the acetic acid solution, a yield of about 60—65% of  $\alpha$ -homopiperonal is obtained, which is further purified by conversion into the additive product with sodium hydrogen sulphite.  $\alpha$ -Homopiperonal is a light yellow oil, b. p.

131—133°/8 mm.,  $d_4^{20}$  1.2654,  $n_D^{20}$  1.5547, and gives an *oxime*, white needles, m. p. 119°, *semicarbazone*, white crystals, m. p. 176—177°, and *phenylhydrazone*, light yellow crystals, m. p. 176°. K. K.

**Gallaldehyde.** KARL W. ROSENMUND (*Ber.*, 1923, 56, [B], 136).—In reply to the recent observations of Nierenstein (this vol., i, 91), the author maintains that the acidity of gallaldehyde is sufficiently great to prevent its isolation from sodium carbonate solution in the manner described by Nierenstein. H. W.

**A New Compound from Conifer Distillates.** KARL CEDERQUIST and BROR HOLMBERG (*Ber.*, 1923, 56, [B], 298—300).—The formation of a solid product,  $C_{12}H_{16}O$ , was observed in the condensers during the purification of wood spirit distilled without previous neutralisation from pyroligneous acid derived from a mixture of pine wood (80%) and spruce wood (20%). It forms colourless prisms, m. p. 69—70°, and is optically inactive. It appears to be either an aldehyde or a ketone, since it is convertible into a *semicarbazone*, flattened needles or thin prisms, m. p. 198—199°, and two *oximes*, long, flattened prisms, m. p. 110—113°, and hairs or needles, m. p. 85—86°. H. W.

**Action of Organomagnesium Compounds on Nitriles. Action of Magnesium Phenyl Bromine.** LOUIS BARY (*Bull. Soc. chim. Belg.*, 1922, 31, 397—410).—The action of magnesium phenyl bromide on nitriles has been studied to compare it with that of magnesium methyl and ethyl bromides (cf. Bruylants, *Bull. Acad. roy. Belg.*, 1922, [v], 8, 7; Baerts, A., 1922, i, 817). In general far higher yields of ketone are obtained than is the case with the magnesium methyl and ethyl bromides, none at all, for example, being formed when these react with acetonitrile, whereas magnesium phenyl bromide gives a yield of about 45% of ketone. In the case of the aliphatic nitriles, the yield of ketone increases with increase of the length of the carbon chain.

In the case of benzonitrile, the intermediate product, diphenylketimine,  $CPh_2NH$ , was isolated in 75% yield, and is characterised by exceptional stability compared with those ketimines in which an alkyl group is united to the ketonic carbon. This is attributed to the fact that in diphenylketimine there is no possibility of tautomeric change of the type  $NH:CR:CH_2Me \rightleftharpoons NH_2:CR:CHMe$ . The nitrile of cyclopropanecarboxylic acid also gave a good yield of phenylcyclopropylketimine, a liquid of pungent, disagreeable odour, b. p. 135—136°/25 mm.,  $d_4^{20}$  1.0663,  $n_D^{20}$  1.56201. It is rapidly converted by dilute acid into phenyl cyclopropyl ketone (Perkin, T., 1885, 47, 840), a liquid of pleasant odour, b. p. 239°,  $d_4^{20}$  1.0566,  $n_D^{20}$  1.5565. The *semicarbazone* has m. p. 189°.

Phenylacetonitrile, acetonitrile, propionitrile, and *n*-butyronitrile yielded the ketone and condensation products, but the ketimine was not obtained. P. M.

**The Formation of Ketazines, Phenylhydrazones, and Semicarbazones of Ring-substituted Acetophenones.** W. J. BRUNING (*Rec. trav. chim.*, 1922, 41, [ii], 655—686).—In order to

ascertain whether acetophenone derivatives react with hydrazine, phenylhydrazine, and semicarbazide in an analogous manner to those of benzaldehyde, the author has studied the formation of ketazines, phenylhydrazones, and semicarbazones of ring-substituted acetophenones. The general conclusions drawn are (1) that glacial acetic acid is a suitable solvent for the preparation of such phenylhydrazones, (2) that the ketazines are only formed in acid solution, their preparation presenting no difficulty when hydrazine sulphate is used, whilst a boiling solution of hydrazine brings about no reaction, (3) that the nature of the ketone used is related to the speed of formation of the ketazine and conditions the state of equilibrium when formation and decomposition of ketazine are taking place at equal rates, (4) that the formation of the semicarbazones occurs more rapidly in acid than in alkaline or neutral solution, but excess of acid decomposes the semicarbazones into their constituents, and (5) that in some cases the nitro-group in the ortho-position with respect to carbonyl considerably diminishes the reactivity of the carbonyl group. The following substances are described: *p*-acetamidoacetophenoneketazine, yellow crystals, m. p.  $311^{\circ}$ ; *p*-acetamidoacetophenonephenylhydrazine, m. p.  $196-200^{\circ}$ ; *p*-acetamidoacetophenonesemicarbazone, white crystals, decomp.  $220^{\circ}$ ; 3:5-dibromo-*p*-aminoacetophenoneketazine, yellow crystals, decomp.  $297^{\circ}$ ; 3:5-dibromo-*p*-aminoacetophenonesemicarbazone, white crystals, m. p.  $255^{\circ}$  (decomp.); 3:5-dibromo-*p*-acetamidoacetophenone, m. p.  $188-189^{\circ}$ , yielding a ketazine, yellow, m. p.  $344^{\circ}$  (decomp.), a phenylhydrazone, pale yellow crystals, m. p.  $244-246^{\circ}$ , and a semicarbazone, white crystals, decomp.  $325^{\circ}$ ; 3:5-dibromo-*p*-diacetamidoacetophenone, obtained in two modifications, (a) unstable, m. p.  $67^{\circ}$ , which passes after some days into (b) stable, m. p.  $88^{\circ}$ ; 3:5-dibromoacetophenoneketazine, m. p.  $231^{\circ}$ ; 3:5-dibromoacetophenonephenylhydrazine, light yellow needles, m. p.  $109-110^{\circ}$ ; 3:5-dibromoacetophenonesemicarbazone, white crystals, m. p.  $134-135^{\circ}$ , yielding a ketazine, small, yellow crystals, m. p.  $300^{\circ}$ , a phenylhydrazone, yellow crystals, m. p.  $129-134^{\circ}$ , and a semicarbazone, white crystals, decomp.  $265^{\circ}$ ; 3:5-dibromo-2-nitroacetophenone, pale yellow crystals, m. p.  $133-144^{\circ}$ , yielding a ketazine, m. p.  $210^{\circ}$ , a phenylhydrazone, m. p.  $165-166^{\circ}$ , and a semicarbazone, m. p.  $234^{\circ}$  (decomp.); 3:4:5-tribromo-2-nitroacetophenone, white needles, m. p.  $188-189.5^{\circ}$ , yielding a ketazine, yellow needles, m. p.  $244^{\circ}$ , a phenylhydrazone, red crystals, m. p.  $173-174^{\circ}$ , and a semicarbazone, decomp.  $249^{\circ}$ .

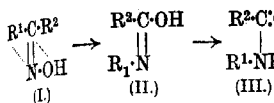

H. J. E.

The Action of an Alcoholic Solution of Potassium Hydroxide on Ketones. VII. The Action of an Alcoholic Solution of Potassium Hydroxide on *p*-Hydroxy- and *p*-Ethoxybenzophenone and their *m*-Bromo-derivatives. P. J. MONTAGNE (*Rec. trav. chim.*, 1922, 41, 703-721; cf. A., 1920, i, 394).—The action of alcoholic potassium hydroxide on benzophenones effects the reduction of the carbonyl group to an alcoholic

group and also, in the case of halogen-substituted benzophenones, the partial replacement of halogen atoms in the ring by hydrogen. A retarding action is exerted by the ethoxyl group in the para-position; this is considerably diminished by the presence of a bromine atom in a similar position in the other ring. In the case of benzophenone itself, heating at  $100^{\circ}$  for two days completes the reduction, whilst on heating 4-ethoxybenzophenone for six days under similar conditions so little change occurs that it is found impossible to isolate the reduction product. On introducing a bromine atom into the meta-position in the ring to which the ethoxyl group is attached, the greater part of the substance is reduced after two days; a second bromine atom in the meta-position in the same ring entirely masks the retarding effect of the ethoxyl group and the substance behaves similarly to benzophenone. The author points out that the action of bromine is similar in the case of 4:4'-dibromo-3:3'-diaminobenzophenone (A., 1917, i, 143). None of the corresponding hydroxybromobenzophenones is reduced even after prolonged heating, so that the effect of the hydroxyl group in inhibiting reduction is not diminished to any appreciable extent by bromine. The products resulting from the action of alcoholic potassium hydroxide on 3:5-dibromo-4-ethoxybenzophenone are 3:5-dibromo-4-ethoxybenzhydrol, 3-bromo-4-ethoxybenzhydrol, and 3:5-dibromo-4-hydroxybenzophenone, the two last-named being formed in small quantity. Hydrolysis of the ethoxyl group thus takes place to a limited extent. The introduction of a second ethoxy-group into the other ring increases the influence of the first and reduction is then incomplete after heating for six days.

The following substances were prepared: 3'-bromo-4-hydroxybenzophenone, crystals, m. p.  $171^{\circ}$ ; 3-bromo-4-ethoxybenzophenone, rhombic bipyramidal crystals ( $a:b:c=0.7935:1:0.2691$ ), m. p.  $102.25^{\circ}$ ; 3-bromo-4-ethoxybenzhydrol, colourless crystals, m. p.  $85^{\circ}$ ; 3:5-dibromo-4-ethoxybenzophenone, colourless, monoclinic crystals ( $a:b:c=1.0901:1:0.8591$ ;  $\beta=59^{\circ}41'$ ), m. p.  $83.5^{\circ}$ , b. p.  $244^{\circ}/11$  mm.; 3:5-dibromo-4-ethoxybenzhydrol, small needles, m. p.  $81.75^{\circ}$ ; 3'-bromo-4-ethoxybenzophenone, colourless crystals, m. p.  $79.5^{\circ}$ , b. p.  $232^{\circ}/11$  mm.; 3-bromo-4-ethoxybenzhydrol, needles, m. p.  $43^{\circ}$ ; 3:5-dibromobenzophenone, m. p.  $75^{\circ}$ , b. p.  $232^{\circ}/18$  mm.; 4:4'-diethoxybenzophenone, small, colourless plates, m. p.  $132^{\circ}$ , b. p.  $258^{\circ}/15$  mm.; 4:4'-diethoxybenzhydrol, crystals, m. p.  $50^{\circ}$ . 4-Ethoxybenzophenone crystallises in the monoclinic system ( $a:b:c=0.7427:1:1.6049$ ;  $\beta=87^{\circ}58'$ ). H. J. E.

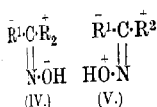

**Formation and Transformation of the Naphthyl Ketoximes.** ERNST BECKMANN, OTTO LIESCHE, and ERICH CORRENS (*Ber.*, 1923, 56, [B], 34<sup>1</sup>—354).—The isomerism of ketoximes has been explained by Hantzsch and Werner in accordance with the principles of ethylenic isomerism and the arbitrary but plausible assumption that the vicinal groups in these compounds exchange places during the course of the Beckmann transformation has been generally accepted until recently. Bucherer, however (*Lehrbuch der Farbenchemie*, 1914), has put forward a scheme in which the

subsidiary valencies (I) are considered to become converted under the conditions of the change into principal valencies with consequent

conversion of the form I into form II, from which the stable modification (III) of the transformation product is readily derived. The transformation thus consists in a change of position between the hydroxyl group and the oppositely situated radicle. Similar views have been expressed more recently by Biltz and Robl (A., 1921, i, 891) and by Meisenheimer (A., 1922, i, 152, 176). The conception has the advantage that the chemical unity of the molecule is regarded as being in a measure preserved throughout the change whereas the direct exchange of position of two neighbouring groups is scarcely possible without intermediate rupture of the molecule.

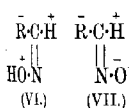

Confirmation of this view of the transformation is deduced in a somewhat different manner. In accordance with Abegg's electrochemical view of the stability of oximes, the disposition of the relatively positive and negative radicles in the alkali-stable and "acid-stable" oximes must be that shown in the annexed formulæ (IV) and (V). It is found that in the "alkali-stable" form the

more strongly negative radicle, R<sup>1</sup>, wanders, whereas in the "acid-stable" variety the less strongly negative radicle, R<sup>2</sup>, migrates during the Beckmann change. The evidence is based on the behaviour of the phenyl naphthyl ketoximes (Betti and Becciolini,

A., 1916, i, 49; Poccianti, A., 1915, i, 822) and the dinaphthyl ketoximes in which, in accordance with the dissociation constants of the corresponding carboxylic acids, the phenyl and β-naphthyl groups are considered to be about equally negative and considerably inferior in this respect to the α-naphthyl radicle.

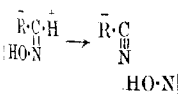

Difficulties appear to be encountered when these views are applied to aldioximes. The varieties which readily yield nitriles

are in general favoured by the action of acids and to them the constitution VI must be ascribed, whereas the isomerides which can be successively esterified and hydrolysed without undergoing decomposition must have the configuration, VII. This, however, is

contrary to the accepted view that the water-forming groups must be obtained from vicinal positions in the compound. The

change is possibly explicable in accordance with the annexed scheme. In any case it appears to be established that in the acid-stable variety of aldioximes (*syn*-oxime) the hydrogen, as positive radicle, wanders when the change results

in the formation of a nitrile or when a normal Beckmann rearrangement occurs.

*Di-β-naphthylketoxime*, needles, m. p. 180—181°, is converted by phosphorus pentachloride in the presence of anhydrous ethyl ether into *β-naphtho-β-naphthylamide*, colourless, lustrous needles, m. p. 239°, the constitution of which is established by its synthesis from *β-naphthoyl chloride* and *β-naphthylamine*. *Di-α-naphthylketoxime*, small, colourless needles, m. p. 200°, is transformed similarly into *α-naphtho-α-naphthylamide*, m. p. 241°. *α-Naphthyl-β-naphthyl ketone*, m. p. 135°, is prepared by the action of magnesium *α-naphthyl bromide* on *β-naphthonitrile* (the intermediate compound,  $\alpha\beta\text{-(C}_{10}\text{H}_7)_2\text{C:N-MgBr}$ , yellow crystals, m. p. 255°, was isolated); it is converted quantitatively in acid solution at 135—140° into *α-naphthyl β-naphthyl ketoxime*, m. p. 171°, which is transformed into *α-naphtho-β-naphthylamide*, colourless needles, m. p. 200°, identical with the product obtained by the action of *α-naphthoyl chloride* on *β-naphthylamine*. H. W.

**Studies in the Anthracene Series. IV.** EDWARD DE BARRY BARNETT and MARCUS AURELIUS MATTHEWS (T., 1922, 123, 380—394).

**Benzaurin.** RICHARD MEYER and WILLY GERLOFF (*Ber.*, 1923, 56, [B], 98—104).—In a previous communication (Meyer and Fischer, A., 1913, ii, 167) it has been shown that the absorption spectrum of benzaurin is so similar to that of fuchsone that it must almost necessarily be regarded as a *p*-hydroxyfuchsone,  $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{CPh}\cdot\text{C}_6\text{H}_4\cdot\text{O}$ . Analysis of the dye, however, gives results which are in harmony with the formula  $\text{OH}\cdot\text{CPh}(\text{C}_6\text{H}_4\cdot\text{OH})_2$ . It is found, however, that a molecular proportion of water is readily lost when the dye is heated, and that the residue has the composition of *p*-hydroxyfuchsone. Benzaurin is therefore regarded as a hydrate of *p*-hydroxyfuchsone. This conception explains the behaviour of the substance when dissolved in alcohol or acetic acid (Meyer and Fischer, *loc. cit.*), the deepening in colour observed when the alcoholic solution is warmed and the formation of an orange-coloured solution in the cold acid being attributable to the withdrawal of water and the production of the more intensely coloured *p*-hydroxyfuchsone.

Since benzaurin obtained by Doebner's method, from benzotrichloride and phenol (*p*-hydroxybenzophenone is formed as by-product) is not crystalline and has not a definite melting point, various attempts have been made to secure a more definitely homogeneous product. The oxidation of 4:4'-dihydroxytriphenylmethane, m. p. 161° (acetate, m. p. 115°), or the hydrolysis of benzaurin diacetate, m. p. 119°, or *benzaurin dibenzoate*, colourless needles, m. p. 183—184°, did not lead to the desired result. More success is obtained by decomposing benzaurin perchlorate (cf. Pfeiffer, A., 1917, i, 210) with the requisite quantity of sodium hydroxide and subsequently adding dilute sulphuric acid, whereby benzaurin is caused to separate as a brilliant red precipitate. It loses one molecular proportion of water at 110—120°.

*Benzaurin hydrochloride*, dark red needles, is obtained by the

addition of an excess of fuming hydrochloric acid to a solution of benzaurin in glacial acetic acid. H. W.

**Di- and Tri-hydroxydeoxybenzoins.** ERNEST CHAPMAN and HENRY STEPHEN (T., 1923, 123, 494-499).

**The Reactivity of Doubly-conjugated Unsaturated Ketones.**  
**IV. The Effect of Substitution on the Reactivity of 4'-Dimethylamino-2-hydroxydistyryl Ketone.** ISIDOR MORRIS HEILBRON and ABRAHAM BRUCE WHITWORTH (T., 1923, 123, 238-245).

**The Benzilic Acid Transformation.** I. G. SCHEUING (*Ber.*, 1923, 56, [B], 252-259).—It is shown that the bluish-violet dye which is produced during the preparation of benzilic acid from benzil and ethyl-alcoholic potash has no direct effect on the transformation. The attempts which have been made previously to explain the course of the benzilic acid transformation assume the rupture of one or both double bonds between the carbon and oxygen atoms of benzil by the addition of water or potassium hydroxide. Such compounds have now been isolated.

*Benzil potassium hydroxide*,  $C_{14}H_{10}O_2.KOH$ , small, indistinct, pale yellow crystals, is obtained when an intimate mixture of benzil and dry potassium hydroxide is triturated beneath a little pyridine or benzene, or by the addition of a concentrated alcoholic solution of potassium hydroxide to a cold solution of benzil in ether. It is decomposed into its components by water and into potassium hydrogen carbonate and benzil by dry carbon dioxide. It is converted slowly at 0°, in a few hours at the atmospheric temperature, and almost instantaneously at 80°, into potassium benzilate, so that it appears to be a definite intermediate product of the conversion of benzil into benzilic acid.

In a similar manner, the addition of a solution of potassium in methyl alcohol and ether to an ethereal solution of benzil leads to the separation of the compound  $C_{14}H_{10}O_2.MeOK.MeOH$ , small, almost colourless crystals, which is decomposed by water, alcohol, or carbon dioxide in the same manner as the product from potassium hydroxide. On the other hand, it does not undergo a similar smooth transformation, which only occurs to the extent of 15% when it is preserved beneath ether during two days at the atmospheric temperature. The product of the change is benzilic acid, whereas methyl benzilate or methoxydiphenylacetic acid would be expected. Transformation does not take place to any considerable extent when it is heated in the presence of benzene; the main products are unchanged benzil and benzoïn, the latter being formed owing to the reducing action of potassium methoxide. *Benzil sodium ethoxide*,  $C_{14}H_{10}O_2.EtONa$ , a pale yellow, distinctly crystalline substance, is prepared by the addition of sodium ethoxide dissolved in a mixture of ethyl alcohol and xylene to a solution of benzil in the latter solvent. The formation of benzil potassium ethoxide can only be observed at a low temperature; it becomes altered in an unexplained manner at 0°. H. W.

**The Beckmann Transformation in the Cases of *o*- and *p*-Quinoneoximes.** ERNST BECKMANN and OTTO LIESCHE (*Ber.*, 1923, 56, [B], 1—23).—The experiments described do not establish beyond all doubt the normal course of the Beckmann transformation in the cases of *p*- and *o*-quinones. The expected enlargement of the ring appears to be proved most conclusively in the instance of anthraquinonemonoxime. The direct action of the transforming agents on dioximes does not appear to lead to the production of an eight-membered ring containing two nitrogen atoms, but this seems possible in the case of anthraquinone if the monoxime is first transformed and the product converted into its oxime and again transformed.

I. *Phenanthraquinone- and naphthaquinone-oxime* [with HERBERT DIETRICH].—The action of phosphorus pentachloride on  $\beta$ -naphthaquinoneoxime [2-nitroso- $\alpha$ -naphthol] has been studied by Borsche and Sander (*A.*, 1915, i, 299), who have isolated a product to which they ascribe the constitution  $\text{COCl}\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{CH}\cdot\text{CN}$ , but for which the cyclic structure,  $\text{C}_6\text{H}_4\cdot\begin{smallmatrix} \text{CCl}=\text{N} \\ \text{CH}\cdot\text{CH} \end{smallmatrix}\text{CO}$ , appears to the authors to

be equally possible. The same chloride, colourless, matted needles, m. p.  $80^\circ$ , is obtained by the action of phosphorus pentachloride on the oxime in the presence of light petroleum. It is converted by ammonia in the presence of anhydrous ether into the substance  $\text{C}_{10}\text{H}_6\text{ON}_2$ , m. p.  $207^\circ$ , and by boiling water into the monobasic acid,  $\text{C}_{10}\text{H}_6\text{O}_2\text{N}$ , m. p.  $179^\circ$ , the *silver*, *sodium*, *potassium*, and *barium* salts of which are described. It is hydrolysed by boiling aqueous sodium hydroxide solution to *o*-carboxycinnamic acid, m. p.  $184^\circ$  (the *silver* salt is described). The action of a saturated solution of hydrogen chloride in a mixture of glacial acetic acid and acetic anhydride or of benzenesulphonyl chloride in the presence of pyridine on  $\beta$ -naphthaquinoneoxime gives the acid,  $\text{C}_{10}\text{H}_6\text{O}_2\text{N}$ , m. p.  $179^\circ$ , the properties of which appear to the authors to be compatible with either the cyclic or open structure.

$\beta$ -Naphthaquinonedioxime is converted by phosphorus pentachloride in the presence of light petroleum by the Beckmann mixture and by benzenesulphonyl chloride and pyridine into the anhydride,  $\text{C}_{10}\text{H}_6\text{ON}_2$ , m. p.  $81^\circ$ , the ready formation of which causes a stabilisation which inhibits the Beckmann transformation.

$\alpha$ -Naphthaquinonemonoxime [4-nitroso- $\alpha$ -naphthol] does not undergo a smooth transformation with any of the reagents investigated. With Beckmann's mixture, it yields a compound,  $\text{C}_{12}\text{H}_8\text{O}_3\text{NCl}_2$ , long needles, m. p.  $165^\circ$  after previous softening. With benzenesulphonyl chloride and pyridine, the *ester*,

$\text{C}_6\text{H}_4\cdot\begin{smallmatrix} \text{C}(\text{O}\cdot\text{SO}_2\cdot\text{h})\cdot\text{CH} \\ \text{C}(\text{NO})=\text{CH} \end{smallmatrix}$ , colourless, matted needles, m. p.  $182$ —

$184^\circ$ , is produced.  $\alpha$ -Naphthaquinonemonoxime is not affected by boiling acetyl chloride, but is converted by the cold reagent into ill-defined compounds containing halogen. The *acetyl* derivative,

$\text{C}_6\text{H}_4\cdot\begin{smallmatrix} \text{C}(\text{OAc})\cdot\text{CH} \\ \text{C}(\text{NO})=\text{CH} \end{smallmatrix}$ , lustrous, brown needles, m. p.  $132.5^\circ$ , is obtained readily by the action of acetic acid and acetic anhydride;

it does not yield homogeneous products when treated with the transforming agents.

$\alpha$ -Naphthaquinonedioxime is converted by the Beckmann mixture into the corresponding diacetate, m. p. 164°, which is transformed by the reagent at a higher temperature into ill-defined chlorinated compounds.

II. *Benzoquinone- and Anthraquinone-oximes* [with A. PHILIPPICH VON PHILIPPSBERG].—*p*-Benzoquinonemonoxime is converted by benzenesulphonyl chloride in the presence of pyridine into the corresponding ester, m. p. 131°, which (without being isolated) is transformed by being further heated and subsequently treated with sulphuric acid into the compound,  $\text{CO} \begin{smallmatrix} \text{CH:CH}\cdot\text{CO} \\ \text{CH:CH}\cdot\text{NH} \end{smallmatrix}$ , yellowish-

brown needles, m. p. 224°. The substance dissolves in solutions of alkali hydroxides and carbonates yielding solutions from which the cobalt, silver, molybdenum, manganese, tin, zinc, lead, and iron salts are prepared; it gives a benzoyl derivative, leaflets, m. p. 189—190°.

Many attempts are described to effect the transformation of *p*-benzoquinonedioxime, but these have not been successful. Apparently the conversion only occurs if a certain minimum temperature is exceeded (below which only salt formation takes place). With the compound in question, this temperature is so high that, when augmented by the local and unavoidable heat of the reaction, it causes the extensive decomposition of the products of the change.

Anthraquinonemonoxime is converted by a mixture of phosphorus pentachloride and acetyl chloride into the compound,

short, colourless needles, m. p. 245°, which is transformed by successive treatment with boiling sodium hydroxide solution and acid into 2-*o*-aminobenzoylbenzoic acid,  $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{C}_6\text{H}_4\cdot\text{CO}_2\text{H}$ , m. p. 199° (decomp.), the silver, lead, and copper salts of which are described. It yields a methyl ester, m. p. (indefinite) 168—173°. The presence of the amino-group is established by its ability to yield a diazo-compound. Anthraquinonemonoxime is converted by a mixture of phosphorus pentachloride and phosphoryl chloride into the phosphoric acid derivative, which is isolated as the silver salt,  $\text{CO} \begin{smallmatrix} \text{C}_6\text{H}_4 \\ \text{C}_6\text{H}_4 \end{smallmatrix} \text{C:N}\cdot\text{O}\cdot\text{PO}(\text{OAg})_2$ , whereas benzenesulphonyl chloride and pyridine transform it into the corresponding ester,  $\text{C}_6\text{H}_5\text{O}_2\text{NS}$ , slender, colourless needles, m. p. 154°. The transformation product,  $\text{C}_{14}\text{H}_9\text{O}_2\text{N}$ , is converted by further treatment with hydroxylamine hydrochloride in boiling alcoholic solution

(86%) into the corresponding oxime,  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{C}(\text{NOH}) \\ \text{CO}\cdot\text{HN} \end{smallmatrix} \text{C}_6\text{H}_4$ , colourless needles, m. p. 243° (decomp.) [*benzoyl* derivative, m. p. 206°], which is converted by the Beckmann mixture at 170° into

phthalyl-*o*-phenylenediamine,  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{CO}\cdot\text{NH} \\ \text{CO}\cdot\text{NH} \end{smallmatrix} \text{C}_6\text{H}_4$ , m. p. 275—

278°, identical with the product synthesised by Anderlini and Meyer (A., 1906, i, 765), for which, however, an alternative constitution has been suggested by Thiele and Falk (A., 1906, i, 750).  
H. W.

**Arylamine Salts of the Anthraquinonesulphonic Acids.**  
A. G. PERKIN and W. G. SEWELL (*J. Soc. Chem. Ind.*, 1923, 42, 27—31†).—The arylamine salts of the anthraquinonesulphonic acids are well-defined crystalline substances, sparingly soluble in water or alcohol. They are readily obtained by adding an acid solution of the arylamine hydrochloride to a solution of the sodium salt of the sulphonic acid. The salts are useful for the purification of the alkali salts of the sulphonic acids, and they can also be used for transforming one alkali or alkaline-earth salt into another, as they are easily reconverted into a metallic salt by boiling with the requisite quantity of either aqueous or alcoholic alkali or alkaline-earth hydroxide. Certain of these salts, notably the aniline salts, can be employed with fair exactitude for the analysis of anthraquinone-mono- and -di-sulphonates by titrating a suspension of the aniline salt in boiling water with standard alkali hydroxide in presence of phenolphthalein. Advantage can be taken of the sparing solubility of the methylaniline, compared with the dimethylaniline  $\beta$ -sulphonates, to effect a fairly complete separation of methylaniline from a mixture of the two bases, provided it is present in considerable amount. The following are among the salts described: *Aniline anthraquinone-2-sulphonate*, colourless needles, m. p. 309°; *p-toluidine anthraquinone-2-sulphonate*, colourless needles, m. p. 308°;  *$\alpha$ -naphthylamine 2-sulphonate*, m. p. 253°; *aniline anthraquinone-1-sulphonate*, m. p. 284°; *methyl-aniline anthraquinone-2-sulphonate*, m. p. 202—203°; *dimethylaniline 2-sulphonate*, m. p. 192—194°; *1-sulphonate*, m. p. 215°; *diethyl-aniline anthraquinone-2-sulphonate*, m. p. 174—175°; the aniline salts of the following anthraquinonedisulphonic acids, 1:5-, orange-yellow crystals; 1:8-, needles; 2:6-, plates; and 2:7-, plates; none of these salts exhibited a melting point. The *methyl-aniline* salts of the 1:5-disulphonic acid, m. p. 251°, orange plates; 1:8-disulphonic acid, 2:6-disulphonic acid, needles, m. p. 205—210°, and 2:7-disulphonic acid, m. p. 230°, are described, as also are the corresponding dimethylaniline salts. *Quinoline anthraquinone-1-sulphonate* melts at 195°, and the *2-sulphonate* at 225°. *Pyridine anthraquinone-1-sulphonate* forms needles, m. p. 158°.  
G. F. M.

**The Camphor Series. II.** SHIGERU KOMATSU (*Mem. Coll. Sci. Kyoto*, 1922, 6, 55—72).—[With KITARO FUJII].—Applying Reformatzky's synthesis to *d*-camphor, using ethyl, *l*-menthyl, and *d*-bornyl esters of iodoacetic acid, esters of bornylacetic acid were obtained, all of which gave the same *l*-isobornylacetic acid on hydrolysis. *Ethyl isobornylacetate*,  $C_{15}H_{26}O_2$ ,  $C(OH)CH_2CO_2Et$ , is a viscous liquid, b. p. 108—112°/3 mm.,  $[\alpha]_D^{25} -24.97^\circ$ . *l*-Menthyl isobornylacetate was obtained as a syrup. *d*-Bornyl isobornylacetate, m. p. 196—197°, has  $[\alpha]_D^{25} +17.44^\circ$ . *l*-Bornylacetic acid,

prepared from the ethyl ester, had  $[\alpha]_D^{20}$   $-20.32^\circ$ , from the *d*-menthyl ester,  $-19.85^\circ$ , and from the *d*-bornyl ester,  $-25.62^\circ$ , all in alcohol. For the barium salt in water, values of  $[\alpha]_D^{20}$  from  $9.53^\circ$  to  $12.91^\circ$  were observed.

[With SHOZO YAMAGUCHI.]—When *d*-camphoroxime was reduced by Forster's method in amyl alcohol with sodium, *d*-bornylamine and *l*-isobornylamine were formed in the proportions of 65.9% of the former to 34.1% of the latter. The high proportion of laevo compound formed, compared with the proportion of *l*-borneol formed by the reduction of *d*-camphor, 19%, may be attributed to the influence of the more positive amino-group on the asymmetric transformation of the carbonyl carbon atom in the camphor molecule. When *d*-bornylamine was passed over thoria at  $400^\circ$ , it was decomposed into camphene and ammonia.

[With RISABURO NAKAI.]—When *d*-borneol was passed over thoria at  $400^\circ$  with ammonia gas, no bornylamine was formed, but *d*-camphene was obtained; in the same way, *l*-borneol gave *l*-camphene. It is probable that camphene was not formed directly from borneol by the Wagner rearrangement, but through the intermediate formation of bornylamine which, as shown above, decomposes into camphene and ammonia. Both *d*- and *l*-camphene gave the same *l*-isocamphene when reduced with hydrogen in presence of nickel. Some specimens of *d*-camphene were found to solidify on keeping; the crystals had m. p.  $50^\circ$ ,  $[\alpha]_D^{20} +17.61^\circ$ . The question of the existence of solid and liquid forms of camphene is being further investigated.

E. H. R.

**Pinene of Spanish Turpentine.** A. MADINAVEITIA (*Anal. Fis. Quim.*, 1922, 20, 531–533).—By fractional distillation of different samples of Spanish turpentine, collecting the fraction  $154.5$ – $157^\circ$ , yields of pinene varying from 35 to 90% are obtained. Except in the case of turpentine from *Pinus halepensis*, the pinene obtained is dextrorotatory. The differences in yield of pinene by fractional distillation are attributed to the presence of varying amounts of nopinene.

G. W. R.

**Castelamarin—A Bitter Principle from *Castela Nicholsoni*.** LOUIS PIERRE BOSMAN (*T.*, 1923, 123, 207–210).

**Chinese Tannin.** J. HERZIG (*Ber.*, 1923, 56, [B], 221–228).—The methylation of Chinese tannin by means of diazomethane has been reinvestigated and methylotannin (cf. Herzig and Tscherne, A., 1905, i, 254) has been prepared in excellent yield. As judged by the specific rotation and methoxyl content, the product must be regarded as homogeneous; if this is the case, the yields show that the parent substance of methylotannin must be present to the extent of at least about 90% in Chinese tannin. Additional evidence of the chemical individuality of Chinese tannin is thus adduced (cf. Iljin, A., 1914, i, 587; Freudenberg, A., 1922, i, 1170). The main reason for the poor yields of methylotannin which have been encountered frequently is to be found in ester transformation, which leads to the production of methyl trimethoxy-

benzoate. In two instances, methyl pentamethyl-*m*-digallate was isolated and this appears to be the first instance in which this compound has been prepared from Chinese tannin directly. The improvement in the methylation of the tannin is brought about by the preliminary, repeated distillation of the ethereal solution of the diazomethane at as low a temperature as possible, and with the help of a dephlegmator. The residue, after removal of the excess of the reagent and desiccation in a vacuum, is solid and can be powdered; occasionally it is obtained directly in pulverulent form. It is almost completely insoluble in cold methyl alcohol, after treatment with which it has a methoxyl content almost identical with that of methylotannin obtained previously. After further purification from warm methyl alcohol, it has  $[\alpha]_D^{25} + 12.44^\circ$ ,  $[\alpha]_D^{25} + 12.75^\circ$ ,  $[\alpha]_D^{25} + 12.22^\circ$  in benzene solution (2%), whereas Herzig and Renner (A., 1909, i, 713) found  $+9^\circ$  to  $+11^\circ$ .

#### [Tannins and Similar Substances. II. Chinese Tannin.]

KARL FREUDENBERG and WILHELM SZILASI (*Ber.*, 1923, 56, [B], 406).—The preparation of highly active Chinese tannin (A., 1922, i, 1169) only succeeds when the crude tannin,  $[\alpha]_D^{25} + 90^\circ$ , has remained for a protracted period in aqueous solution in contact with aluminium hydroxide.

H. W.

**Reduction of an Indanthrene Dye by Means of Sodium Hyposulphite.** JOHN H. YOE and GRAHAM EDGAR (*J. Physical Chem.*, 1923, 27, 65—73).—The reaction between an oxyindanthrene dye (Ponsol-yellow-G) and sodium hyposulphite has been investigated, and it is shown that the reduction and solution of the dye involve (a) the comparatively rapid reaction of the dye with the hyposulphite to form an insoluble crystalline reduced dye, and (b) peptisation of the latter by hydroxyl-ions, with the formation of a colloidal solution. The rate of solution and the amount of dye peptised by a given solution depend on the state of subdivision of the dye. Positive ions tend to coagulate the solution and to retard the peptisation of the reduced dye.

J. S. G. T.

**Ability of Alkaloids to Form Oxides. Oxygenase of the Bach-Chodat System.** OBDULIO FERNÁNDEZ and ANTONIO PIZARROSO (*Anal. Fis. Quim.*, 1922, 20, 589—594; cf. Fernandez, A., 1921, i, 485).—The ability of a number of alkaloids and other compounds containing the group  $-\text{CO}-\text{NH}-$  to form oxides in the presence of hydrogen peroxide is investigated. The conclusions drawn are indefinite.

G. W. R.

**Aristolochic Acid.** ARMAND CASTILLE (*J. Pharm. Belg.*, 1922, 4, 569—571; from *Chem. Zentr.*, 1922, iii, 1301).—Aristolochic acid from *Aristolochia clematis*, *A. longa*, and *A. rotundifolia*, is identical with Pohl's aristolochine (A., 1892, 874). It has molecular weight 343 and corresponds with the formula  $\text{C}_{17}\text{H}_{11}\text{O}_4\text{N}$ . It gives on reduction a substance,  $\text{C}_{17}\text{H}_{13}\text{O}_4\text{N}$ , which is characterised by its fluorescence in solution, and probably contains an anthraquinone nucleus.

G. W. R.

**Aldehydes derived from Cinchonine, Quinine, and their Acyl Compounds.** L. SEEKLES (*Rec. trav. chim.*, 1923, 42, 39-104).—When quinine, cinchonine, or their acetyl or benzoyl derivatives are subjected to the action of ozone in cold chloroform solution, addition occurs at the double linking of the vinyl group with formation of an ozonide which, when treated with water, decomposes into formaldehyde and a new aldehyde. The terms quininal and cinchoninal are suggested for the new aldehydes from quinine and cinchonine, respectively. These and a large number of their derivatives are described. *m*-Chloropiperic acid (3-chloro-2:4:6-trinitrophenol) was found useful for obtaining derivatives of the new aldehydes, since it readily precipitated them in a crystalline form and an estimation of chlorine provided a ready method of analysis. The following new salts of this acid were prepared.

Quinine+2X (X=*m*-chloropiperic acid), yellow, m. p. 217° (decomp.); cinchonine+X, yellow, crystalline, clusters, m. p. 198°; +2X, greenish-yellow crystals, m. p. 209°; acetylcinchonine+X, greenish-yellow, m. p. 188°; +2X, yellow, m. p. 143-144°; benzoylcinchonine+X, yellow, m. p. 140-141°; +2X, yellow, m. p. 156°; acetylquinine+2X, m. p. 139°; benzoylquinine+X, greenish-yellow, m. p. 129-130°; +2X, yellow crystals, m. p. 150°.

Acetylcinchonine when pure has  $[\alpha]_D^{25} +139.5^\circ$  in water containing 3 mols. HCl; it could not be crystallised. Acetylquinine under the same conditions has  $[\alpha]_D^{25} -120.8^\circ$ , m. p. 116°. It crystallises in the bisphenoidal class of the rhombic system, *a*:*b*:*c*=1.1142:1:0.6119.

Acetylcinchonine ozonide forms a white, voluminous mass, softening at 75°, decomposing at 95-100°. Acetylcinchoninal was obtained as a white, amorphous substance having a marked tendency to polymerise, m. p. 106-109°;  $[\alpha]_D^{25} +28.2^\circ$ . Attempts to hydrolyse the acetyl group were unsuccessful. It forms a *mono-m-chloropiperic*ate, m. p. 155°, and a *di-m-chloropiperic*ate, m. p. 156-165°. The *phenylhydrazone* of acetylcinchoninal is an amorphous powder, m. p. 135-142°, *acetate*, amorphous, m. p. 106°; *p-bromophenylhydrazone*, yellow powder, m. p. 126°, *acetate*, yellow, m. p. 105°; *p-nitrophenylhydrazone*, yellow powder, sintering from 125°, m. p. 134°, decomp. 141°; *acetate*, yellow, m. p. 90°. When the last was recrystallised from alcohol, small, yellow crystals, m. p. 226°, were obtained, but were not identified. The *phenylhydrazone* forms a *m-chloropiperic*ate, m. p. 154-165° (decomp.). Acetylcinchoninal also forms a compound with ammonia and one with sodium hydrogen sulphite.

Benzoylcinchonine ozonide forms a white, voluminous mass decomposing at about 100°. Benzoylcinchoninal is a white substance, m. p. 130° (decomp.);  $[\alpha]_D^{25} -72.4^\circ$ . Its *mono-m-chloropiperic*ate forms greenish-yellow crystals, m. p. 165°, and the *di-m-chloropiperic*ate, yellow crystals, m. p. 165°. The *phenylhydrazone* is amorphous, yellow, m. p. 117-118°, *acetate*, m. p. 127°; *p-bromophenylhydrazone*, orange, amorphous, m. p. 120-122°, *acetate*, m. p. 112-114°; *p-nitrophenylhydrazone*, yellow, m. p. 126-127°.

127° (decomp.), *acetate*, m. p. 130—131°. An aldehyde-ammonia compound is indicated.

*Acetylquinine ozonide* forms a very voluminous, white mass, softening at 75°, decomposing at 90—105° with evolution of gas. *Acetylquininal* is a white substance, m. p. about 120° (decomp.),  $[\alpha]_D^{25} - 63.5^\circ$ . It forms a *mono-m-chloropicate*, greenish-yellow, m. p. 166° (decomp.), and a *di-m-chloropicate*, yellow, softening and decomposing from 138°. The *phenylhydrazone* is a yellow substance, m. p. about 125°, *acetate*, very hygroscopic, yellow, m. p. 65°; *p-bromophenylhydrazone*, yellow, m. p. 120°; *p-nitrophenylhydrazone*, yellow, m. p. 125°. *Acetylquininalammonia* is a white powder, m. p. 82—85°.

*Benzoylquinine ozonide* is a voluminous, white mass, m. p. 95—100°. *Benzoylquininal* is a white substance, m. p. 126°;  $[\alpha]_D^{25} + 79.4^\circ$ ; *mono-m-chloropicate*, greenish-yellow, m. p. 142° (decomp.); *di-m-chloropicate*, yellow, blackening at 155°. The *phenylhydrazone* is a yellow powder, softening from 116°, m. p. 128°, *acetate*, m. p. 118°; *p-bromophenylhydrazone*, yellow, m. p. about 125°, *acetate*, softens at 118—119° (decomp.); *p-nitrophenylhydrazone*, yellow, m. p. 122—133°, *acetate*, m. p. 112—115° (decomp.).

*Benzoylquininal-ammonia* is a white substance, m. p. 131—132°, containing 1 mol. of ether. When prepared in benzene solution it separates with 1 mol. of benzene, m. p. 136—139°.

*Cinchonine ozonide* is a white, amorphous substance, not very voluminous, decomposing at 105°. *Cinchoninal*,  $C_{15}H_{29}O_4N_2$ , is a white, amorphous substance, m. p. 143—145°,  $[\alpha]_D^{25} + 100.5^\circ$ ; it readily reduces Fehling's solution and silver nitrate. It forms a *mono-m-chloropicate*, greenish-yellow crystals, decomposing slowly at 151°, and a *di-m-chloropicate*, decomp. at 155°. The *phenylhydrazone* is amorphous, m. p. 130—135°, and decomposes violently at 140°; *p-bromophenylhydrazone*, yellow, m. p. 120°; *p-nitrophenylhydrazone*, m. p. 130—132° (decomp.). These three hydrazones do not form acetates.

*Quinine ozonide* is a white, amorphous substance decomposing at 109°. *Quininal*,  $C_{19}H_{29}O_4N_2$ , forms small colourless crystals, m. p. 160°, having strong reducing properties,  $[\alpha]_D^{25} - 30^\circ$ . The *mono-m-chloropicate* forms yellow crystals, m. p. 130°; *di-m-chloropicate*, a yellow, vitreous substance, m. p. 126° (decomp.). The *phenylhydrazone* has m. p. 145—147°; *p-bromophenylhydrazone*, yellow, m. p. 125—130° (decomp.). Quininal does not form compound with ammonia, but forms an additive compound with sodium hydrogen sulphite in alcohol, decomposed by water.

E. H. R.

**The Synthesis of Ephedrine.** E. FOURNEAU and J. PUYE (*Anal. Fis. Quim.*, 1922, 20, 394—399; cf. Späth, A., 1921, i, 45; Fournau, A., 1905, i, 57; Eberhard, A., 1915, i, 834).—Ephedrine is obtained from phenylethylcarbinol by the following reactions: Dehydration of phenylethylcarbinol gives propenylbenzene; by the action of bromine water, the corresponding bromohydrin is

obtained, b. p. 145—155°/25 mm. By heating the bromohydrin with a 10% methylamine solution in a sealed tube at 120° for three hours, phenyl- $\alpha$ -methylaminoethylcarbinol (ephedrine) is obtained and separated by appropriate methods. After recrystallisation, colourless prisms are obtained, m. p. 60°. The hydrochloride gives m. p. 180°, subsequently rising to 190°. The stereoisomeric  $\psi$ -ephedrine is obtained from ephedrine hydrochloride by way of acetylation of the latter compound, whereby acetyl  $\psi$ -ephedrine is obtained as colourless crystals, m. p. 176°. Acetyl  $\psi$ -ephedrine, by treatment with hydrochloric acid, gives a  $\psi$ -ephedrine hydrochloride, m. p. 175°, from which the base, m. p. 117°, is obtained.

**The Influence of Papaverine on the Optical Activity of Narcotine in Acid Solution.** HAROLD EDWARD ANNETT (T., 1923, 123, 376—379).

[Scopoline. VI. The Constitutions of Scopolamine and Scopoline. The Hofmann Degradation of Scopoline.] J. ADAMER (*Ber.*, 1923, 56, [B], 130—131).—A criticism of the recent communication of Hess and Wahl (A., 1922, i, 854).

H. W.

**Furylethylamine.** YASUHIKO ASAHINA and ATSUSHI FUJITA (*J. Pharm. Soc. Japan*, 1922, 1084—1090).—According to the method of Claisen (A., 1905, i, 286), furfuraldehyde (12 g.) and ethyl chloroacetate (15 g.) were condensed in cold absolute ethereal solution by the aid of metallic sodium (3.5 g.) yielding ethyl furyl-glycidate,  $C_4OH_3CH < \begin{smallmatrix} O \\ CH-CO_2Et \end{smallmatrix}$ , b. p. 114—117°/5 mm. The

ester was saponified with alcoholic potash; the resulting potassium salt was dissolved in water, to which the calculated quantity of hydroxylamine hydrochloride was added when the resulting oxime separated as an oil (Rosenmund and Dornsaft, A., 1920, i, 56). *Furylacetaldoxime*,  $C_4OH_3CH_2CH:N\cdot OH$ , b. p. 90—92°/4 mm., is a light yellow, viscid liquid having a strongly sweet taste (about fifty times that of sucrose). When kept, the oily oxime (*anti*-form) gradually changes into the crystalline stable form (*syn*-form), m. p. 64°, the sweetness being reduced by half. By reduction with 3% sodium amalgam and 50% acetic acid in methyl-alcoholic solution, the oxime is converted into *furylethylamine*,  $C_4OH_3CH_2CH_2\cdot NH_2$ , a colourless liquid, b. p. 155°/762 mm.,  $n_D^{20}$  1.0080,  $n_D^{25}$  1.47994; it has a strongly amine-like odour and absorbs carbon dioxide from the air, the *carbamate*,

m. p. 87°, being formed. The *benzoate* has m. p. 81°. K. K.

**Methylisopyromucic Acid and a Method of Characterising Acids of the Sugar Group.** L. J. SIMON and A. J. A. GUILLAUMIN (*Compt. rend.*, 1922, 175, 1208—1211; cf. Chavanne, A., 1905, i, 77).—As *isopyromucic acid* may be prepared by dehydration of a dibasic acid derived from a hexose or of a monobasic acid

derived from a pentose, dehydration of a methyl pentose was effected, the lactone of rhamnose being used. The homologue of isopyromucic acid thus obtained, *methylisopyromucic acid*,  $C_8H_8O_8$ , is of yellow colour, m. p.  $133^\circ$ . Oxidation by the sulpho-chromic mixture shows the presence of a methyl group directly linked to carbon. The acid has a strong reducing action on silver salts and on permanganate. Its *benzoyl* derivative, m. p.  $121^\circ$ , may be prepared by the action of benzoyl chloride either directly or in alkaline solution. It is not a true acid, but rather a phenol,  $CH \begin{smallmatrix} \text{C(OH)CO} \\ \text{CH=CMc} \end{smallmatrix} O$  (cf. Chavanne, A., 1902, i, 637, 690); the coloration with ferric chloride is bluish-green. A method of characterising the acids derived from sugars, details of which are given, depends on the fact that dibasic acids derived from hexoses and monobasic acids derived from pentoses and methyl pentoses give colours with ferric chloride whilst monobasic acids derived from hexoses do not do so. The latter give a positive result after careful oxidation.

H. J. E.

**Selenium Organic Compounds. II. Synthesis of Diarylthiophenes and Diarylselenophenes.** MARSTON TAYLOR BOGERT and PILAR PEREZ HERRERA (*J. Amer. Chem. Soc.*, 1923, **45**, 238—243).—When acetophenoneanil is fused with sulphur at  $220$ — $240^\circ$ , a 28% yield of pure 2:4-diphenylthiophen is obtained. The tollis may be used with equal success, and if substituted acetophenones are used the corresponding diarylthiophenes are obtained. If selenium is used instead of sulphur, the products are diarylselenophenes. The following new compounds are described: *acetophenone-o-tolil*, b. p.  $210$ — $220^\circ/57$  mm.; *p-methylacetophenoneanil*, b. p.  $220$ — $240^\circ/53$  mm.; 2:4-diphenylthiophen-5-mercurichloride, m. p.  $223^\circ$  (corr.); 2:4-diphenylselenophen, m. p.  $112.3^\circ$  (corr.), and its 5-mercurichloride, m. p.  $224^\circ$  (corr.); 2:4-di-p-tolylselenophen, m. p.  $136.3^\circ$  (corr.).

Acetophenonedimethylacetal was prepared by heating together at  $40^\circ$  for several hours methyl orthoformate, acetophenone, anhydrous methyl alcohol, and a trace of concentrated hydrochloric acid. After the mixture had stood for sixteen hours, it was made just alkaline with sodium methoxide and the methyl alcohol distilled off.

W. G.

**Derivatives of Hydroxypyrrole.** ERICH BENARY and RUDOLF KONRAD (*Ber.*, 1923, **56**, [B], 44—52).—Previous attempts to obtain simple hydroxypyrrole derivatives from the hydroxy-esters (Benary and Silbermann, A., 1913, i, 651) by hydrolysis and subsequent removal of carbon dioxide have been unsuccessful on account of the small stability of the pyrrole ring towards alkali hydroxide. Attempts have therefore been made to increase the stability by the introduction of the phenyl group in position 1. The hydrolysis of the esters to the corresponding acids is thus rendered possible, but the subsequent removal of carbon dioxide can only be effected without extensive decomposition if the hydroxyl group is protected by methylation.

Ethyl  $\beta$ -anilinoacrylate is transformed by chloroacetyl chloride in the presence of anhydrous ether and pyridine into a mixture of ethyl  $\beta$ -anilino- $\alpha$ -chloroacetylacrylate,  $\text{NHPh}\cdot\text{CH}_2\text{C}(\text{CO}\cdot\text{CH}_2\text{Cl})\cdot\text{CO}_2\text{Et}$ , needles, m. p.  $83^\circ$ , and ethyl  $\text{N}$ -chloroacetyl- $\beta$ -anilinoacrylate,  $\text{CH}_2\text{Cl}\cdot\text{CO}\cdot\text{NPh}\cdot\text{CH}_2\text{CH}\cdot\text{CO}_2\text{Et}$ , colourless prisms, m. p.  $136\text{--}137^\circ$ . The former ester is transformed by a cold alcoholic solution of potassium hydroxide into ethyl 4-hydroxy-1-phenylpyrrole-3-carboxylate,  $\text{NPh}\langle\begin{smallmatrix} \text{CH}_2\text{C}\cdot\text{CO}_2\text{Et} \\ \text{CH}_2\text{C}\cdot\text{OH} \end{smallmatrix}\rangle$ , colourless, matted needles, m. p.  $83\text{--}84^\circ$ .

The corresponding acid crystallises in small rods, m. p.  $172\text{--}174^\circ$  (decomp.), and becomes resinified when heated above its melting point in a vacuum. The hydroxy-ester is converted by amyl nitrite into ethyl 5-oximino-4-keto-1-phenylpyrroline-3-carboxylate, lemon-yellow, hexagonal prisms, decomp. about  $185^\circ$  after softening and gradually melting above  $175^\circ$ ; if an excess of sodium nitrite is gradually added to a solution of the ester in glacial acetic acid, an isomeric product,  $\text{C}_{13}\text{H}_{12}\text{O}_4\text{N}_2$ , almost colourless, coarse needles, m. p.  $157\text{--}158^\circ$ , is formed, the constitution of which has not been elucidated. 4-Acetoxy-1-phenylpyrrole-3-carboxylic acid, colourless needles, m. p.  $145\text{--}147^\circ$ , is produced from the hydroxy-acid, acetic anhydride, and anhydrous sodium acetate; when heated at the atmospheric pressure or in a vacuum, it loses carbon dioxide and acetic acid, and leaves a black, resinous residue. Ethyl 4-hydroxy-5-benzeneazo-1-phenylpyrrole-3-carboxylate, orange-yellow needles, m. p.  $170\text{--}172^\circ$ , after previous softening, could not be hydrolysed to the corresponding acid,  $\text{NPh}\langle\begin{smallmatrix} \text{CH}=\text{C}\cdot\text{CO}_2\text{H} \\ \text{C}(\text{N}\cdot\text{NPh})\cdot\text{C}\cdot\text{OH} \end{smallmatrix}\rangle$ ,

which, however, is prepared by the action of benzenediazonium chloride on an alkaline solution of the hydroxy-acid; it crystallises in orange-coloured needles, m. p. about  $185\text{--}187^\circ$  after softening at  $175^\circ$ . It is decomposed with loss of aniline when heated in a vacuum. 4-Methoxy-1-phenylpyrrole-3-carboxylic acid is prepared by the action of methyl sulphate on the hydroxy-acid and subsequent hydrolysis of the methyl ester; it forms leaflets, m. p.  $166\text{--}167^\circ$  (decomp.) [the potassium salt, long, colourless needles, is described]. The acid loses carbon dioxide when heated in a vacuum at  $180\text{--}200^\circ$ , and yields 3-methoxy-1-phenylpyrrole,  $\text{NPh}\langle\begin{smallmatrix} \text{CH}_2\text{C}\cdot\text{H} \\ \text{CH}_2\text{C}\cdot\text{OMe} \end{smallmatrix}\rangle$ , colourless needles, m. p.  $33\text{--}34^\circ$ , which when molten or dissolved rapidly become brown on exposure to air. Attempts to hydrolyse the methoxyl to the hydroxyl group by aluminium chloride, hydrogen chloride, or hydrogen bromide were unsuccessful owing to the instability of the free hydroxypyrrole.

Methyl  $\beta$ -anilino- $\alpha$ -chloroacetylcrotonate is converted by potassium hydroxide in methyl alcoholic solution into methyl 4-hydroxy-1-phenyl-2-methylpyrrole-3-carboxylate,  $\text{NPh}\langle\begin{smallmatrix} \text{CMe}\cdot\text{C}\cdot\text{CO}_2\text{Me} \\ \text{CH}=\text{C}\cdot\text{OH} \end{smallmatrix}\rangle$ , small needles, m. p.  $123\text{--}124^\circ$ ; the corresponding acid crystallises in colourless needles, m. p.  $145^\circ$ . The hydroxy-ester is converted by amyl nitrite into methyl 5-oximino-4-keto-2-methyl-1-phenyl-

*pyrroline-3-carboxylate*,  $C_{13}H_{13}O_4N_2$ , pale yellow needles, m. p. 185–187° (decomp.), from which the corresponding acid,  $C_{15}H_{15}O_4N_2$ , small, pale yellow needles, m. p. 171–172° (decomp.), is obtained. Sodium nitrite converts the hydroxy-ester dissolved in glacial acetic acid into *methyl 5-nitroimino-4-keto-1-phenyl-2-methylpyrroline-3-carboxylate*, orange-coloured needles, m. p. 192–193° (decomp.) after previous softening. H. W.

**The Action of Diazomethane on Dyes and certain Nitro-pyrroles.** WILLIAM KÜSTER and WILHELM MAAG (*Ber.*, 1923, 56, [B], 55–69).—It has been shown previously (Küster, A., 1922, i, 885) that the action of diazomethane on bilirubin leads to the introduction of two methyl groups into the molecule and in addition a molecule of diazomethane is combined, forming a compound,  $C_{36}H_{42}O_6N_8$ . A further investigation of this compound and comparison of its properties with those of substances obtained by the action of diazomethane on pyrrole derivatives led the authors to the conclusion that a portion of the bilirubin molecule must contain the pyrrolenylmethanepyrrol group.

The product,  $C_{36}H_{42}O_6N_8$ , of the addition of diazomethane to esterified bilirubin is a red, amorphous powder which contains three methyl groups eliminable by hydriodic acid. It can be prepared in a crystalline form resembling bilirubin by the action of diazomethane on pure bilirubin and bilirubinammonia suspended in anhydrous ether; it, however, passes readily into the resinous variety.

Indigoid ethyl bis-2-methylpyrroline-3-carboxylate (Benary and Silbermann, A., 1913, i, 652) contains two carbethoxy-groups which are readily hydrolysed by hydriodic acid at 140°, whereas a further evolution of alkyl iodide is not observed below 300°; it is converted by diazomethane in the presence of ether into a red resin.

*Methyl 5-3'-acetyltetronylidene-4-keto-2-methylpyrrole-3-carboxylate*,  $CO_2Et-C-CO > C-C < CH_2-CH_2-O$   
 $Me-C-NH > C-C < C(CMe-OH)-CO$  yellow needles, m. p. 190°

(decomp.), is prepared by the action of alcoholic potassium hydroxide solution on a mixture of acetyltetronamide and ethyl chloroacetylaminocrotonate; it is converted by diazomethane into a reddish-brown resin,  $C_{16}H_{19}O_6N$ , m. p. 75° (decomp.).

Ethyl 5:5'-bis-4-keto-2-methylpyrroline-3-carboxylate hydrate,  $C_{16}H_{20}O_6N_2.H_2O$  (cf. Benary and Silbermann, *loc. cit.*), loses two ethyl groups under the action of hydriodic acid at 140°, and does not suffer further loss of alkyl iodide below 340°; it is converted by diazomethane into a yellow, brittle resin,  $C_{18}H_{24}O_5N_2$ , m. p. 73–74° (decomp.).

3-Hydroxy-4-carbethoxy-5-methylpyrrolenyl-2-furylmethane,  $C_{13}H_{13}O_4N$  (Küster, A., 1922, i, 858), combines with hydrogen chloride in the presence of acetone to form a *hydrochloride*,  $C_{13}H_{14}O_4NCl$ , rust-brown needles, which readily lose hydrogen chloride on exposure to air. The substance is converted by diazomethane into a dark brown resin. 3-Hydroxy-4-carbethoxy-5-methyl-2-o-pyrrolenylhydroxyphenylmethane, brownish-yellow needles,

m. p. 207° (decomp.), is readily prepared from Benary's pyrrole and salicylaldehyde, and is transformed by diazomethane into a yellow resin, m. p. about 40° after previous darkening.

Ethyl 2 : 5-dimethylpyrrole-3-carboxylate is oxidised by chromic acid to *carbethoxymaleinimide*,  $C_7H_7O_4N$ , colourless needles, m. p. 115°.

Benary's indigoid pyrrole (*loc. cit.*) is oxidised by nitric acid (*d* 1.4) at 0° to ethyl 5-nitro-2 : 4-dihydroxypyrrrole-3-carboxylate, colourless needles, decomp. 100°. The potassium salt,  $C_7H_7O_6N_2K$ , decomp. 167°, barium salt, decomp. 165°, lead, and copper salts are described. Hydrogen sulphide reduces the nitro-compound to a colourless substance, m. p. 121°. The ester is readily hydrolysed to 5-nitro-2 : 4-dihydroxypyrrrole-3-carboxylic acid, colourless needles, decomp. 124°, the ammonium and silver salts of which are described; the methyl ester crystallises in colourless needles, decomp. 112°. Ethyl 5-nitro-2-hydroxy-4-methoxypyrrrole-3-carboxylate, a pale yellow liquid, b. p. 146°, which solidifies to needle-shaped crystals when cooled with ice, is readily prepared by the action of diazomethane on the corresponding dihydroxy-ester. 5-Nitro-2-hydroxy-4-methoxypyrrrole-3-carboxylic acid crystallises in colourless needles; the ammonium salt, silver salt, and the methyl ester, a colourless liquid, b. p. 145°, are described.

Ethyl 5-nitro-4-hydroxy-2-methylpyrrole-3-carboxylate, colourless needles, m. p. 100.5° (decomp.), is readily hydrolysed to 5-nitro-4-hydroxy-2-methylpyrrole-3-carboxylic acid, colourless needles, decomp. 124°. It is converted by diazomethane into ethyl 5-nitro-4-methoxy-2-methylpyrrole-3-carboxylate. H. W.

**The Tetrachlorodipyridinoiridates. Configurations of the Two Series of Iridiumdipyridinotetrachloro-compounds.** MARCEL DÉLÉPINE (*Compt. rend.*, 1922, 175, 1211—1213; cf. this vol., i, 135).—These are neutral un-ionised substances. *cis*- and *trans*-Isomerides exist which are derived from the orange and red salts, respectively. They are not of equal stability towards oxidising agents, and are themselves of unequal oxidising power. Both decompose iodides according to the equation  $Ir(C_5H_5N)_2Cl_4 + MI \rightarrow Ir(C_5H_5N)_2Cl_4M + I$ , but only the *cis*-compound decomposes bromides. This is consistent with the fact that bromine can be used only in preparing the orange salts. The author concludes that the *cis*-isomeride behaves as a halogen intermediate between chlorine and bromine, and the *trans* as intermediate between bromine and iodine. The constitution was determined by reason of the dichroism of the chloride derived from the orange salt, which is isomorphous with and confers the property of dichroism on platinum tetrachlorodipyridine,  $PtCl_4(C_5H_5N)_2$ . It has been shown (Werner and Fassbender, A., 1897, i, 631; Jörgensen, A., 1901, i, 163) that the latter substance has the *cis*-configuration, hence the same configuration is inferred for the orange salts. The red salts have, therefore, the *trans*-configuration. H. J. E.

#### β-Ketonic Nitriles and their Relation to Cyclic Compounds.

E. P. KOHLER and B. L. SOUTHER (*J. Amer. Chem. Soc.*, 1922, 44, 2903—2914; cf. this vol., i, 54).—Cyanoacetamide and cyano-

acetonitrile, like methyl cyanoacetate, condense with phenyl styryl ketone, but the three products, although closely related, behave differently towards most reagents. All three form cyclic compounds under the influence of halogen acids in indifferent media. The product from methyl cyanoacetate forms a tetrahydropyridine derivative, in the production of which the cyano-group is involved and molecular rearrangement occurs. The product from cyanoacetamide also forms a tetrahydropyridine derivative, but in its production the amide group is involved. Under the same conditions, the product from the dinitrile forms only a trace of a tetrahydropyridine derivative, the main product being a mixture composed of a pyridine and a hexahydropyridine derivative. This mixture is doubtless due to a series of reactions starting with the addition of halogen acid to one of the cyano-groups and ending with the spontaneous oxidation and reduction of an intermediate dihydropyridine derivative. The results confirm the view that such oxidation-reduction reactions are associated with the extraordinary activity of hydrogen which is in combination with atoms that are flanked on both sides by unsaturated groups; but they do not support the conclusion of Knoevenagel and his co-workers (cf., A., 1903, i, 785) that hydropyridine derivatives are incapable of reacting in all possible desmotropic modifications.

Cyanoacetamide condenses with phenyl styryl ketone under the conditions previously described (*loc. cit.*) to give  $\alpha$ -cyano- $\gamma$ -benzoyl- $\beta$ -phenylbutyramide, m. p. 161–163°, and similarly cyanoacetitrile yields  $\alpha$ -cyano- $\gamma$ -benzoyl- $\beta$ -phenylbutyronitrile, m. p. 125–126°. When dry hydrogen chloride or bromide is passed into a chloroform solution of the above amide, 2-keto-3-cyano-4:6-diphenyltetrahydropyridine, m. p. 220°, is obtained, and this on hydrolysis with concentrated sulphuric acid yields 2-keto-3-carbamyl-4:6-diphenyltetrahydropyridine, m. p. 181–182°, and when treated with nitrous acid gives 1-hydroxy-3-cyano-4:6-diphenylpyridine, m. p. 313–315°. With alcoholic ammonia, the dihydropyridine derivative undergoes spontaneous oxidation-reduction and the products are a hydroxypyridine and 2-keto-3-cyano-4:6-diphenylpiperidine, m. p. 188–189°.  $\alpha$ -Cyano- $\gamma$ -benzoyl- $\beta$ -phenylbutyronitrile also reacts with halogen acids in dry chloroform solution. With hydrogen chloride, one of the products is 2-chloro-3-cyano-4:6-diphenylpyridine, m. p. 154.5°, and with hydrogen bromide 2-bromo-3-cyano-4:6-diphenylpyridine, m. p. 169–170°, is obtained. In the latter reaction a red oil was also formed from which after pouring it into a solution of sodium hydrogen carbonate 2-keto-3-carbamyl-4:6-diphenylpiperidine, m. p. 170°, was isolated, and this on treatment with hydrogen chloride in methyl alcohol gave methyl 2-keto-4:6-diphenylpiperidine-3-carboxylate, m. p. 177°.

With alkalis, the cyanoamide additive product, m. p. 161–163°, described above, is transformed into its cyclic isomeride, the only other product being a trimolecular compound. With alcoholic alkalis, the dinitrile additive product gives pyridyl ethers, of which 2-methoxy-3-cyano-4:6-diphenylpyridine, m. p. 110°, and 2-ethoxy-3-cyano-4:6-diphenylpyridine, m. p. 112°, were prepared.

The rearrangement of the cyanoacetamide additive product to cyclic compounds takes place so easily that only cyclic bromo-compounds were obtained from it, even when the bromination was carried out in the presence of potassium acetate. From the dinitrile, however, it was possible to obtain one open-chain bromo-compound by brominating it in the presence of potassium acetate. The behaviour of this substance towards halogen acids confirms the view previously expressed (*loc. cit.*) regarding the mechanism by which bromopyridine derivatives are formed when bromine acts on open-chain ketonic nitriles, since when dry hydrogen chloride is passed into a chloroform solution of the bromo-compound the product is a chloropyridine derivative. The compounds described are:  $\alpha$ -bromodi- $\alpha$ -cyano- $\gamma$ -benzoyl- $\beta$ -phenylbutyronitrile, m. p. 126–127°, 5-bromo-2-keto-3-cyano-4 : 6-diphenyltetrahydropyridine, m. p. 165°, 5-chloro-2-keto-3-cyano-4 : 6-diphenyltetrahydropyridine, m. p. 178–181°, 3 : 5-dibromo-2-keto-3-cyano-4 : 6-diphenyltetrahydropyridine, m. p. 195° (decomp.), 5-bromo-2-hydroxy-3-cyano-4 : 6-diphenylpyridine, m. p. 303–306° (decomp.), 2-chloro-5-bromo-3-cyano-4 : 6-diphenylpyridine, m. p. 181–182°, and 2 : 5-dibromo-3-cyano-4 : 6-diphenylpyridine, m. p. 189–190°. W. G.

**The Ethoxyquinaldines.** W. T. K. BRAUNHOLTZ (*J. Amer. Chem. Soc.*, 1922, **44**, 2967; cf. T., 1922, **121**, 169).—In reference to a paper by Gutekunst and Gray (A., 1922, i, 950), the author directs attention to the preparation and description of the 5-, 6-, and 7-ethoxyquinaldines by himself (*loc. cit.*). W. G.

**The Constitution of Dianhydrodiacetylanthranilic Acid.** GUSTAV HELLER and HERBERT GRUNDMANN (*Ber.*, 1923, **56**, [B], 200–205).—The action of phosphoryl chloride on acetylanthranilic acid or its esters or on acetylanthranil has yielded a compound which Anschütz and Schmidt (A., 1903, i, 56) designate dianhydrodiacetylanthranilic acid, and to which they assign the constitution

$$\text{C}_6\text{H}_4 \begin{array}{c} \text{C}(\text{OH})\cdot\text{CH}\cdot\text{CO}\cdot\text{NH} \\ \text{NH}\cdot\text{CO}\cdot\text{CH}\cdot\text{C}(\text{OH}) \end{array} \text{C}_6\text{H}_4 \text{ or } \text{C}_6\text{H}_4 \begin{array}{c} \text{C}(\text{OH})\cdot\text{CH}_2\cdot\text{CO}\cdot\text{N} \\ \text{N}\cdot\text{CO}\cdot\text{CH}_2\cdot(\text{HO})\text{C} \end{array} \text{C}_6\text{H}_4.$$

This compound has now been obtained incidentally by the action of acetic anhydride on benzene- or *p*-toluene-sulphonylanthranilic acid, and is shown to be the *o*-carboxyanilide of 4-hydroxy-2-methylquinoline-3-carboxylic acid,

*p*-Toluenesulphonylanthranilic acid is converted by boiling acetic anhydride into the mixed *anhydride* of toluene-*p*-sulphonic acid and the *o*-carboxyanilide of 4-hydroxy-2-methylquinoline-3-carboxylic acid,  $\text{C}_6\text{H}_4 \begin{array}{c} \text{C}(\text{OH})\cdot\text{C}\cdot\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{O}\cdot\text{SO}_2\cdot\text{C}_6\text{H}_4\text{Me} \\ \text{N}=\text{CMe} \end{array}$ , pale yellow crystals, m. p. 214–215° (decomp.). The substance is decomposed by dilute sodium hydroxide solution into the *o*-carboxyanilide of 4-hydroxy-2-methylquinoline-3-carboxylic acid, m. p. 249–250° (decomp.), identical with the product obtained by Anschütz and Schmidt (*loc. cit.*). It is converted by glacial acetic

and concentrated hydrochloric acids at 130—140° into 4-hydroxy-2-methylquinoline. A substance,  $C_{13}H_{13}O_2N_2S$ , slender needles, m. p. 133.5°, is obtained as by-product of the action of acetic anhydride on *p*-toluenesulphonylanthranilic acid. It appears to contain acetic anhydride and solvent of crystallisation; when deprived of this it has m. p. 159—160° (decomp.), but the amount of it available was insufficient for an extended examination.

Benzenesulphonylanthranilic acid is transformed by boiling acetic anhydride into the mixed *anhydride*,  $C_{15}H_{13}O_5NS$ , slender needles, m. p. 157—158°.

*p*-Toluenesulphonylanthranilic acid is transformed by glacial acetic and concentrated hydrochloric acids at 140° into *anthranilic acid toluene-p-sulphonate*,  $C_{14}H_{15}O_5NS$ , slender needles, m. p. 218° (decomp.). The corresponding benzenesulphonate has m. p. 230° (decomp.). H. W.

**The Constitution of Naphtholisatin and its Derivatives.** C. CÂNDEA (*Bull. Acad. Sci. Roumaine*, 1922, 8, 31—39).—Colourless condensation products of isatin with  $\alpha$ -naphthol were prepared. These differ from similar compounds obtained from phenols in that they are almost insoluble in alkaline solutions, are not oxidised to coloured substances, and do not form acetyl derivatives. The condensation probably occurs at the 3-position of the indole nucleus (cf. Dănilă and Căndeia, A., 1916, i, 417). The derivatives obtained were: *Di- $\alpha$ -naphtholisatin*,  $C_{28}H_{19}O_3N$ , prismatic needles, m. p. above 300°. *Di- $\alpha$ -naphtholmonobromoisatin*,  $C_{28}H_{18}O_3NBr$ , prismatic needles, m. p. above 300°. *Di- $\alpha$ -naphtholdibromisatin*,  $C_{28}H_{17}O_3NBr_2$ , prismatic needles, m. p. above 300°. *Di- $\alpha$ -naphtholmonochlorisatin*,  $C_{28}H_{18}O_3NCl$ , crystals, m. p. above 300°. *Di- $\alpha$ -naphtholdichloroisatin*,  $C_{28}H_{17}O_3NCl_2$ , prismatic needles, m. p. above 300°. H. J. E.

**Stereochemical Studies. VII. 2-Thion-4-methylthiazoline-3-acetic Acid.** BERTIL GROTH and BROR HOLMBERG (*Ber.*, 1923, 56, [B], 289—298).—2-Thion-4-methylthiazoline-3-acetic acid,  $S < \begin{smallmatrix} CS-N-CH_2-CO_2H \\ CH:CM_e \end{smallmatrix}$ , pale honey-yellow, thick plates or short prisms, m. p. 198—199° (decomp.), is prepared in 87% yield by the action of chloroacetone on an aqueous solution of glycine hydrochloride and potassium hydroxide which has been agitated with carbon disulphide until the latter is completely dissolved; it dissolves in water to the extent of 2.06 g. per litre at the atmospheric temperature. The *sodium* salt, rectangular plates (+5H<sub>2</sub>O), *barium* salt, rosettes of needles (+2H<sub>2</sub>O), *methyl* ester, almost colourless needles, m. p. 96—97°, and *ethyl* ester, long, almost colourless needles, m. p. 97—98°, are described. The acid could not be resolved into its optical antipodes by treatment with *l*- or *d*-phenylethylamine in aqueous or alcoholic solution; the salts of the *r*-acid with the optically active bases were isolated (m. p. 161—162° and 160—162°). The acid is unusually stable towards hydrolysis by acid or alkali. It is oxidised by nitric acid (or less

conveniently by bromine water) to the inner anhydride of 2-keto-4-methylthiazoline-3-acetic acid,  $\text{CO} \begin{smallmatrix} \text{CH}_2\text{N}^+\text{CMe} \\ \text{O}-\text{CH}-\text{S} \end{smallmatrix} \text{CH}$ , which is isolated as the hydrogen sulphate,  $\text{C}_6\text{H}_7\text{O}_2\text{SN}_2\text{H}_2\text{SO}_4$ , a colourless, crystalline, somewhat hygroscopic substance, m. p. 114–115°, to a turbid liquid. The corresponding hydrochloride (anhydrous and monohydrate) is described; it has m. p. above 230° (decomp.) after darkening at 200° and becoming black at 230°. The free base is a colourless, crystalline powder (+2.5H<sub>2</sub>O), m. p. 110–115° (decomp.) after softening and becoming discoloured at 95°, m. p. (anhydrous) 165° (decomp.). It is stable in hot aqueous, acidic solution, but is readily decomposed in neutral or alkaline solution with the formation of ill-defined products. It was not found possible to isolate the corresponding acid, since the tendency towards dehydration is so marked that the anhydride can exist even in faintly alkaline solution. H. W.

#### Stereochemical Investigations of the Diketothiazolidines.

I. STEN KALLENBERG (*Ber.*, 1923, 56, [B], 316–331).—In contrast to the  $\psi$ -thiohydantoins and the rhodanines, the diketothiazolidines which have a mobile hydrogen atom attached to the asymmetric  $\beta$ -carbon atom, exhibit normal stereochemical relationships. They can readily be prepared in optically active forms which easily undergo racemisation in consequence of the possibility of desmotropic change.

Potassium ethylthiocarbamate,  $\text{NHEt}\cdot\text{CO}\cdot\text{SK}$ , is prepared conveniently by the action of carbon oxydisulphide on a solution of potassium hydroxide and ethylamine hydrochloride in absolute alcohol. Under certain conditions, particularly with regard to concentration, it reacts with a solution of sodium *l*-bromosuccinate in cold water to give *d*-ethylcarbamidothiolsuccinic acid,

small plates,  $[\alpha]_D +103.5^\circ$  in absolute alcoholic solution. The acid is readily decomposed by concentrated ammonia with the production of *d*-thiomalic acid, by warm acids to *d*-thiomalic acid, carbon dioxide, and ethylamine, on the one hand, and to *r*-diketo-ethylthiazolidineacetic acid,  $\begin{smallmatrix} \text{NEt}\cdot\text{CO} \\ \text{CO}-\text{S} \end{smallmatrix} \text{CH}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ , on the

other, by alkalis into *d*-thiomalic acid, carbon dioxide, and amine. *r*-Ethylcarbamidothiolsuccinic acid crystallises in colourless, thin prisms or short needles, m. p. 141–142° (decomp.).

The action of cold concentrated hydrochloric acid on *d*-ethylcarbamidothiolsuccinic acid gives a mixture of *r*-diketoethylthiazolidineacetic acid, colourless prisms, m. p. 113–115°, and the corresponding *d*-acid which, however, could not be caused to crystallise. The racemic acid can be resolved with the aid of active phenyl-ethylamine, but the active acids are again obtained only in the form of non-crystalline syrups.

*d*-Methylcarbamidothiolsuccinic acid, prepared from potassium methylthiocarbamate and sodium *l*-bromosuccinate, has m. p. 114–116° (decomp.),  $[\alpha]_D +99.2^\circ$  in absolute alcoholic solution.

The corresponding *r*-acid crystallises in colourless, spherical aggregates, m. p. 135—136° (decomp.). The active acid is converted by concentrated hydrochloric acid into *d*-diketomethylthiazolidineacetic acid, transparent prisms, m. p. 101—102°,  $[\alpha]_D +208.0^\circ$  in absolute alcoholic solution (the success of the reaction greatly depends on the conditions of the experiment, which are described in detail in the original). It is converted in alkaline solution into *r*-methyl-carbamidothiolsuccinic acid. Since *d*-methylcarbamidothiolsuccinic acid is not racemised under similar conditions, it follows that *d*-diketomethylthiazolidineacetic acid must be converted into the corresponding *r*-compound previously to fission of the thiazole ring. Preliminary measurements show that the velocity of racemisation is diminished with increasing concentration of hydrogen-ions and increased by increasing concentration of hydroxyl-ions. *r*-Diketomethylthiazolidineacetic acid crystallises in small, colourless plates, m. p. 98—99°.

*d*-Dimethylcarbamidothiolsuccinic acid forms colourless prisms, m. p. 138—139° (decomp.),  $[\alpha]_D +81.7^\circ$  in absolute alcoholic solution. It is decomposed by hot *N*-sodium hydroxide solution to a small extent into thiomalic acid, carbon dioxide, and dimethylamine, but the greater portion is constitutionally unchanged and only slightly racemised. Similar treatment with *N*-sulphuric acid causes an almost complete fission into partly racemised thiomalic acid; concentrated hydrochloric acid at the atmospheric temperature gives the same result, except that fission is less extensive and racemisation of the products more pronounced.

H. W.

**The Tautomerism of Amidines. I. 2:4- and 2:5-Diphenylglyoxalines.** RICHARD BURTLES and FRANK LEE PYMAN (T., 1923, 123, 361—367).

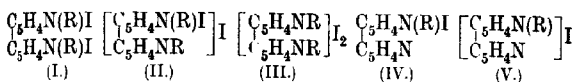

**The Tautomerism of Amidines. II. The Alkylation of Open-chain Amidines.** FRANK LEE PYMAN (T., 1923, 123, 367—370).

**Some New Hypnotics of the Barbituric Acid Series.** H. A. SHONLE and A. MOMENT (*J. Amer. Chem. Soc.*, 1923, 45, 243—249).—Various dialkyl- and alkylaryl-barbituric acids were prepared and tested for hypnotic action. The monoalkyl- and aryl-derivatives were found to be inactive in doses of 0.5 to 1 g. per kg. of body weight when injected subcutaneously in rabbits. Dimethylbarbituric acid was without any apparent action on rabbits in a dose of 0.75 g. per kg. of body weight. Then as the molecular weight increased the activity increased until a maximum was reached, after which it declined until the hypnotic activity was lost and the animal showed only muscular inco-ordination or no effect at all, as was the case with dibenzylbarbituric acid. However, the length and type of the carbon atom chains of the entering groups play an important part in modifying the activity. Branched chains are more active and less toxic than are the straight chains. Of the aliphatic compounds investigated, ethylisoamylbarbituric

acid was found to be the most active as well as to possess the lowest toxicity. The relative activities of the barbituric acid derivatives tested are tabulated. New malonic esters prepared are as follows: *ethyl-sec.-butylmalonic ester*, b. p. 155–160°/60 mm.,  $d_{20}^{25}$  0.9858,  $n_D^{25}$  1.4264; *ethylisobutylmalonic ester*, b. p. 119–120°/8 mm.,  $d_{20}^{25}$  0.9682,  $n_D^{25}$  1.4228; *ethylisoamylmalonic ester*, b. p. 150°/20 mm.,  $d_{20}^{25}$  0.9540,  $n_D^{25}$  1.4255; *propylisopropylmalonic ester*, b. p. 143°/42 mm.,  $d_{20}^{25}$  0.9803,  $n_D^{25}$  1.4239; *isopropyl-n-butylmalonic ester*, b. p. 136°/14 mm.,  $d_{20}^{25}$  0.9742,  $n_D^{25}$  1.4291.

New derivatives of barbituric acid are *ethylisobutylbarbituric acid*, m. p. 174–176°, *ethylisoamylbarbituric acid*, m. p. 154–156°, *isopropyl-n-butylbarbituric acid*, m. p. 209–210°, *n-propylisopropylbarbituric acid*, m. p. 161–162°, *isopropylisoamylbarbituric acid*, m. p. 173–175°, *propylisoamylbarbituric acid*, m. p. 129–132°, *ethyl-sec.-butylbarbituric acid*, m. p. 155–157°. W. G.

**The Colour of the 2:2'-Dipyridylum Halogenides.** BRUNO EMMERT and JULIUS STAWITZ (*Ber.*, 1923, 56, [B], 83–91).—An extensive series of 4:4'-dipyridylum di- and mono-alkyl halides has been examined. The various colours which they exhibit in substance and when dissolved and the failure of their solutions to observe Beer's law, are explained by the application of Hantzsch's views on the constitution of ammonium salts.

The constitution I is ascribed to the red dipyridylum di-iodides and the corresponding pseudo-form, IV, to the yellow monoiodides. The yellow hydrates of the di-iodides have the constitution II, whereby the difference between their colour and that of the anhydrous compounds and their similarity with the monoiodides is explained. In the aqueous and alcoholic solutions of the di-iodides, the three forms, I, II, and III, are present in equilibrium, the two latter being electrolytically dissociated. In a similar manner, the failure of the monoiodides to obey Beer's law in solution is explained by the equilibrium between the yellow molecules (IV) and the colourless molecules (V).

The following individual compounds are described: 4:4'-*Dipyridyl dihydriodide*, red prisms, and the corresponding *mono-hydriodide* (golden-yellow prisms, +1H<sub>2</sub>O and anhydrous). The corresponding *dihydrobromide*, long, pale yellow needles, *mono-hydrobromide*, colourless, prismatic needles (+H<sub>2</sub>O), and *mono-hydrochloride* (+H<sub>2</sub>O). 4:4'-*Dipyridyl monomethiodide*, a pale yellow, crystalline powder, and the corresponding *hydriodide*. 4:4'-*Dipyridyl dimethobromide*, yellow prisms. 4:4'-*Dipyridyl diethiodide*, orange-coloured prisms, and the corresponding *mono-ethiodide*, lustrous, yellow leaflets. 4:4'-*Dipyridyl dipropiodide*, red crystals, which yields a *pentahydrate* on exposure to moist air, the *monopropiodide*, yellow crystals, the *dipropobromide*, greenish-yellow crystals, and the *dipropochloride*, colourless, lustrous leaflets.

which deliquesce on exposure to air. 4:4'-Dipyridyl methiodide propiodide, red, oblique prisms. 4:4'-Dipyridyl monoisobutiodide, which closely resembles the monopropiodide. 4:4'-Dipyridyl monoisoamyliodide. 4:4'-Dipyridyl di-sec.-hexyliodide, a brownish-red substance, di-hydrate, yellow needles. 4:4'-Dipyridyl di-benzyliodide, a red substance which gives an unstable, yellow hydrate, dibenzylbromide and the corresponding pale yellow tetrahydrate.

H. W.

Some Derivatives of Methylenediquinaldine and their Relationship to the Carbocyanines. FRANCES MARY HAMER (T., 1923, 123, 246—259).

The Colour of Di- and Tri-2-quinolylmethanes and their Derivatives. GÜNTHER SCHEIBE (*Ber.*, 1923, 56, [B], 137—148; cf. A., 1921, i, 62, 451; 1922, i, 1190).—Di- and tri-2-quinolylmethanes exist in colourless and coloured forms which yield an equilibrium mixture in solution or in the molten condition. The former varieties can be represented satisfactorily by formulæ of the type  $\text{CH}_2(\text{C}_9\text{H}_6\text{N})_2$ , but the coloured compounds do not possess the quinonoid structure,  $\text{C}_9\text{H}_6\text{N}:\text{CH}:\text{C}_9\text{H}_6\text{N}:\text{NH}$ , since their absorption spectra differ entirely from those of the 1-alkyl derivatives. The hydrogen atom is not attached directly to the central carbon atom or to either nitrogen atom, but as it is shown by the chemical reactions of the compounds to be related to all three, it must be ascribed a position within their sphere of influence. The optical effect of this mode of union of the hydrogen appears to be similar to that of the union of the anion in the dye salts, although it is not ionisable. In this case, ionisation does not appear to have an immediate relationship to optical properties.

[With R. PFLOCK, K. SCHOLL, and E. FRIEDEL].—Di-2-quinolylmethane is prepared without particular difficulty by the process described recently (A., 1922, i, 1190); the success of the operation depends on the presence of small quantities of hydrogen chloride such as are usually retained by 2-chloroquinoline. König's failure to prepare the compound (A., 1922, i, 1188) is due to the use of too carefully purified materials.

A cold solution of di-2-quinolylmethane in alcohol is converted by four molecular proportions of nitric acid into the dinitrate,  $\text{C}_{18}\text{H}_{14}\text{N}_2\cdot 2\text{HNO}_3$ , colourless, lustrous leaflets. The salt is converted when heated by itself or in alcoholic solution into nitro-di-2-quinolylmethane mononitrate,  $\text{NO}_2\cdot\text{CH}(\text{C}_9\text{H}_6\text{N})_2\cdot\text{HNO}_3$ , yellow plates, decomp.  $145^\circ$ ; this is converted by sodium hydroxide into a colourless, crystalline substance, which, after desiccation in a toluene bath, gives the sodium salt of the mononitro-compound,  $\text{C}_{18}\text{H}_{12}\text{O}_2\text{N}_3\text{Na}$ , yellow crystals, m. p.  $282^\circ$ . Nitro-di-2-quinolylmethane crystallises in yellow needles, m. p.  $200^\circ$ . It appears to yield only monoacid salts even with an excess of mineral acid. It is converted by nitric acid in warm glacial acetic acid solution into dinitro-di-2-quinolylmethane,  $\text{C}(\text{C}_9\text{H}_6\text{N})_2(\text{NO}_2)_2$ , almost colourless prisms, m. p.  $140^\circ$ .

Tri-2-quinolylcarbinol is converted by acetic anhydride and

sodium acetate into the corresponding *acetate*,  $C_{30}H_{21}O_2N_3$ , colourless prisms, m. p.  $190^\circ$ .

Bromine and tri-2-quinolylmethane yield *tri-2-quinolylbromomethane*,  $C_{28}H_{18}N_3Br$ , colourless crystals, m. p.  $169^\circ$ . It gives a *di-picrate*, and is converted by alcoholic potassium hydroxide solution into *tri-2-quinolylmethyl ethyl ether*, colourless crystals, m. p.  $179^\circ$ , and a compound of high melting point which appears to be the ether derived from two molecules of the carbinol. It is smoothly reduced by phenylhydrazine in the presence of benzene to tri-2-quinolylmethane.

*p*-Dimethylaminobenzylidenepicoline forms pale yellow crystals, m. p.  $139^\circ$ , and, like the corresponding quinaldine derivative, gives coloured salts with acids, which are immediately decomposed by alkali. Nitrous acid appears to transform the compounds into nitroso-amines, but the investigation of these substances is not complete.

When molecular proportions of acetylacetoneanil, aniline, and zinc chloride are warmed with a little alcohol, the additive compound of the dianil with zinc chloride,  $C_{17}H_{18}N_2 \cdot ZnCl_2$ , colourless prisms, decomp.  $256^\circ$ , is obtained. This suffers decomposition into the monoanil when treated with ammonia. The *dianil monohydrochloride*, yellow prisms, m. p.  $218^\circ$ , is prepared from the monoanil and aniline hydrochloride, but it was not found possible to obtain the crystalline base from the salt.

Acetylacetonecarbamide (cf. Stark, A., 1909, i, 260) which has been prepared in the light and is therefore yellow, melts at  $95^\circ$  to a colourless liquid which re-solidifies at about  $100^\circ$ , becomes yellow when further heated, and has m. p.  $198^\circ$ . Dibenzylideneacetylacetonecarbamide yields a *monohydrochloride*,  $C_{30}H_{17}ON_2Cl$ .

### Contraction of the Ring in the Cases of Quinoxaline Derivatives and a New Method of Formation of Benziminazoles. I.

K. BRAND and E. WILD (*Ber.*, 1923, 56, [B], 105—119).—The condensation of the hydrochlorides of *N*-mono-substituted aromatic *o*-diamines with 1 : 2-dicarbonyl compounds leads in general to the production of quinoxaline derivatives. It is therefore remarkable that benzil and 4-nitro-2-aminophenyl-*p*-tolylamine in the presence of hydrochloric acid yield 5-nitro-2-phenyl-1-*p*-tolylbenziminazole hydrochloride in place of the expected stilbazonium chloride, the 5-membered iminazole ring being formed in place of the expected 6-membered diazine ring. A number of possibly similar instances have also been examined.

5-Nitro-2-phenyl-1-*p*-tolylbenziminazole hydrochloride, colourless, slender needles, m. p.  $235^\circ$ , readily separates when a solution of benzil and 4-nitro-2-amino-4'-methyl-diphenylamine in alcohol is boiled with hydrochloric acid.

Benzil-5-nitro-2-anilinoanil,  $COPh \cdot CPh \cdot N \cdot C_6H_3(NO_2) \cdot NHPh$ , pale yellow needles, m. p.  $205^\circ$ , is slowly converted by sulphuric acid into the  $\psi$ -base of 6-nitro-1 : 2 : 3-triphenylstilbazonium,

m. p. 161°, which is more conveniently prepared by the action of hydrochloric acid on the anil under conditions which are described in detail in the original communication. The anil is transformed by treatment with concentrated hydrochloric acid in boiling alcoholic solution into 5-nitro-1:2-diphenylbenziminazole, m. p. 181° (cf. Walther and Kessler, A., 1906, i, 898); the latter substance is also prepared by the action of hydrochloric acid and alcohol on 6-nitro-1:2:3-triphenylstilbazonium base and from benzil and 4-nitro-2-aminodiphenylamine under somewhat similar conditions.

The 6-chloro-1:2:3-triphenylstilbazonium  $\psi$ -base, yellow needles, m. p. 164°, prepared by the condensation of benzil and 4-chloro-2-aminodiphenylamine in boiling alcoholic solution could not be converted into 5-chloro-1:2-diphenylbenziminazole by treatment with alcohol and hydrochloric acid, even after addition of nitrobenzene to the mixture.

6-Nitro-2:3-diphenylquinoxaline is unchanged when heated at 150–170° with alcohol and hydrochloric acid.

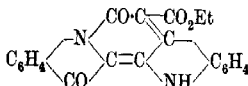

According to the conditions, particularly with respect to the amount of acid used, the action of 4-nitro-2-amino-*N*-methylaniline on benzil in the presence of alcohol and hydrochloric acid leads to the formation of *benzil-5-nitro-2-methylaminomonoanil*, yellow leaflets, m. p. 195°, 6-nitro-2:3-diphenylquinoxaline, 6-nitro-2:3-diphenyl-1-methylstilbazonium chloride, dark yellow needles, m. p. 168° (decomp.), and a substance, m. p. about 280°, which has not been completely investigated. More favourable conditions for the conversion of the anil into 6-nitro-2:3-diphenylquinoxaline and 6-nitro-2:3-diphenyl-1-methylstilbazonium chloride are described in detail. The  $\psi$ -base corresponding with the substance last mentioned crystallises in yellow needles, m. p. 170° (from alcohol), 176° (from benzene); repeated crystallisation from hot alcohol effects its re-conversion into the anil.

H. W.

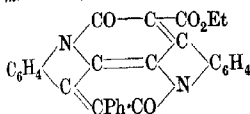

### The Indigotin Group. II. A New Vat Dye Prepared from Indigotin and Ethyl Malonate.

THEODOR POSNER and GOTTFRIED PYL (*Ber.*, 1923, 56, [B], 31–44; cf. Posner and Aschermann, A., 1920, i, 880).—A vat dye derived from indigotin and ethyl malonate has been patented by Posner (D.R.-P. 281998). The full investigation of the product is now described, the substance being of particular interest, since it gives violet-red shades which are quite distinct from the usual indigo colours.

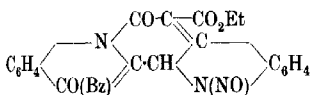

*Ethyl indigotinmalonate* (annexed formula), reddish-violet crystals, m. p. 296–297°, is prepared conveniently by heating a solution of indigotin in nitrobenzene with ethyl malonate and a little solid sodium hydroxide. It may also be obtained in poor yield by the protracted ebullition of a solution of indigotin in a large excess of ethyl malonate; as by-product of the latter action, a *carboxylic acid*,  $C_{18}H_{18}O_{10}$ , m. p. 129°, is formed which has not been investigated completely. It is converted by aqueous alcoholic

potassium hydroxide solution into the corresponding *potassium salt*,  $C_{21}H_{14}O_4N_2.KOH$ , an emerald-green powder. Hydrolysis of the carbethoxy group could not be effected by means of acid or alkali; the protracted action of the latter appears to cause the slow loss of the whole malonyl group without, however, giving a homogeneous product. The introduction of a second malonyl complex into ethyl indigotinmalonate could not be effected, but the compound reacts with phenylacetyl chloride in the presence of boiling xylene to yield *ethyl anhydrophenylacetylindigotinmalonate* (annexed formula), m. p. above  $310^\circ$ . *Ethyl benzoyldihydroindigotinmalonate*,  $C_{23}H_{20}O_5N_2$ , colourless leaflets which become red at about  $192^\circ$  and decompose without melting at a higher temperature, is prepared by reduction of ethyl indigotinmalonate with

sodium hyposulphite in the presence of sodium hydroxide and addition of benzoyl chloride to the solution. The presence of the imino-group in ethyl indigotinmalonate is established by the preparation of *ethyl benzoylindigotinmalonate*,  $C_{23}H_{18}O_5N_2$ , orange-coloured leaflets, m. p.  $240^\circ$ , which is obtained in small yield by boiling the ester and benzoyl chloride, or more conveniently from these substances in the presence of pyridine. Acetyl chloride and pyridine convert ethyl indigotinmalonate into *ethyl acetylindigotinmalonate*, red crystals, m. p.  $182^\circ$ . *Ethyl nitrosoindigotinmalonate*,  $C_{21}H_{13}O_5N_3$ , tile-red crystals, decomp.  $267-270^\circ$ , is prepared by the action of nitrous fumes on a boiling alcoholic suspension of ethyl indigotinmalonate, into which it is re-converted by successive treatment with zinc dust and air. It is not affected by a boiling mixture of acetic anhydride and acetyl chloride, but is converted by benzoyl chloride in the presence of boiling pyridine

into *ethyl benzoylnitrosoindigotinmalonate* (annexed formula), orange-yellow crystals which commence to sublime at  $236^\circ$  and

decompose at  $245-250^\circ$ ; it is hydrolysed by aqueous-alcoholic potassium hydroxide solution to ethyl nitrosoindigotinmalonate.

A compound,  $C_{21}H_{17}O_5N_3$ , small, almost colourless needles, which become red at  $210^\circ$ , is formed during the preparation of ethyl indigotinmalonate.

**2:5-Iminodihydro-1:2:3-triazole. I. Constitution of Dimroth's 5-Anilinotriazole.** PAVITRA KUMAR DUTT (T., 1923, 123, 265-274).

**Purines. IV. The Action of Hydrogen Peroxide on certain Phenyl-substituted Uric Acids.** F. J. MOORE and ELIZABETH S. GATEWOOD (J. Amer. Chem. Soc., 1923, 45, 135-145).—It has

previously been shown (A., 1918, i, 104, 409, 410) that the action of hydrogen peroxide on uric acid may lead to two distinct series of products according to experimental conditions, but the results indicated no intermediate product between uric acid and the final products obtained. With a view to obtain information as to the relationship which may exist between the mechanism of this reaction and that of the permanganate oxidation, certain substituted uric acids have been prepared and their behaviour on oxidation by hydrogen peroxide has been studied.

9-Phenyluric acid on oxidation in alkaline solution with hydrogen peroxide gives *as*-phenylbiuret and a new phenylbiuret, m. p. 196—197.5° (cf. following abstract), together with ammonia, oxalic acid, and phenylcarbamide. 7-Methyluramil when treated in alkaline solution with phenylcarbamide yields 9-phenyl-7-methyl- $\psi$ -uric acid, m. p. 245—250°,  $n_D$  1.636;  $n_D$  1.714+, from which, by boiling with hydrochloric acid, 9-phenyl-7-methyluric acid,  $n_D$  1.887,  $n_D$  1.674, is obtained. On oxidation with hydrogen peroxide in the presence of potassium hydroxide, this uric acid gives oxalic acid, ammonia, and 6-phenyl- $\alpha$ -methylcarbamide. By a similar series of reactions starting with 1:3-dimethyluramil, 9-phenyl-1:3-dimethyl- $\psi$ -uric acid, m. p. 189—190°,  $n_D$  1.525,  $n_D$  1.647, giving a monohydrate, and 9-phenyl-1:3-dimethyluric acid,  $n_D$  1.155+,  $n_D$  1.684, are obtained. The latter compound, on oxidation as above, also yields ammonia, oxalic acid, and 6-phenyl- $\alpha$ -methylcarbamide.

9-Allyl- $\psi$ -uric acid, m. p. 227—228° (decomp.),  $n_D$  1.591,  $n_D$  1.69, is also obtained from the uramil and was converted into 9-allyluric acid,  $n_D$  1.75,  $n_D$  1.775. The optical properties of a number of familiar compounds allied to the above were determined during the work, and the results are tabulated.

From the above results on the oxidation of substituted uric acids, it is considered that the first step in the reaction is the breaking of the bonds between the carbon atoms 2 and 3, 4 and 5 and 5 and 7, forming in the case of 9-phenyluric acid *s*-phenylbiuret and in the cases of the other two the same phenylmethylbiuret. The phenylmethylbiuret then decomposes, giving ammonia, and phenylmethylcarbamide, while the *s*-phenylbiuret partly undergoes a similar decomposition, forming phenylcarbamide, and another portion is rearranged by the ammonia to form *as*-phenylbiuret.

W. G.

**Purines. V. A Third Phenylbiuret.** ELIZABETH S. GATEWOOD (*J. Amer. Chem. Soc.*, 1923, 45, 146—150; cf. preceding abstract).—The new phenylbiuret, m. p. 196—198° (decomp.),  $n_D$  1.559;  $n_D$  1.73, obtained during the oxidation of 9-phenyluric acid by hydrogen peroxide (*loc. cit.*) is clearly distinguished by its properties from the two isomerides already known. It can be converted into *as*-phenylbiuret by the action of ammonia and a great variety of organic bases, but not by alkalis. No method of reversing this change has been discovered. From certain theoretical considerations the author is inclined to the view that

the structure of this new biuret is that of *N*-phenylbiuret, a structure at present assigned by Schiff (A., 1907, i, 206) to the phenylbiuret prepared by Weith (A., 1878, 141). W. G.

**The Upper Limit of Diazotisability in the Benzene Series. Diazo-derivatives of Mesitylene.** GILBERT T. MORGAN and GLYN REES DAVIES (T., 1923, 123, 228—237).

**Azopicric Acid** [2:4:6:2':4':6'-Hexanitro-5:5'-dihydroxyazobenzene]. K. ELBS and FR. SCHLIEPHAKE (*J. pr. Chem.*, [ii], 1922, 104, 282—284).—The nitration of *m*-azophenol (cf. A., 1903, i, 539) by the prolonged action of an ice-cold mixture of concentrated sulphuric acid and potassium nitrate, subsequent treatment with water, and extraction with benzene, leads to the compound of 1 mol. of azopicric acid with 2 mols. of benzene, flat, deep blood-red prisms; this loses benzene gradually, more quickly on warming at 90°, giving a 60% yield of pure *azopicric acid* as a yellowish-red powder, m. p. 238—239° (decomp.), which explodes violently when quickly heated. Azopicric acid dissolves readily in benzene (giving the above-mentioned compound), and also in water, alcohol, ether, or acetone, but is insoluble in carbon disulphide or concentrated hydrochloric acid. In aqueous solution it is a fast dye to wool, and has an astringent (not bitter) taste. The potassium and barium salts are described. W. S. N.

**Capacity to Form Phenylhydrazones.** VI. BERNARDO ODDO and LUIGI PIATTI (*Gazzetta*, 1922, 52, ii, 333—346).—Cryoscopic investigations in anhydrous phenylhydrazine, similar to those already described (A., 1913, i, 1233; 1915, ii, 414, 415), have now been made on a number of compounds containing in the molecule either two carbonyl groups or one carbonyl together with other radicles.

Diacetyl reacts immediately with the phenylhydrazine, giving a precipitate which does not dissolve readily. After a time, however, the liquid becomes almost clear, and the depression of the freezing point gradually attains a value which is 50% of the theoretical value for the diacetyl taken, the formation of the monophenylhydrazone being thus indicated. Later, the phenylosazone is precipitated in increasing amount. Similar difficulties as regards solubility are presented by anthraquinone, with which a clear solution cannot be obtained.

With acetylacetone, the apparent molecular weight rapidly reaches a value equal to 40% of the theoretical value, and subsequently slowly falls to become constant at about one-third the calculated value, the diphenylhydrazone or, more probably, the pyrazole compound being formed:  $\text{OH}\cdot\text{CMe}\cdot\text{CHAc} + \text{NH}_2\cdot\text{NPh} = \text{OH}\cdot\text{CMe}\cdot\text{CH}\cdot\text{CMe}\cdot\text{N}\cdot\text{NPh} + \text{H}_2\text{O} = \begin{matrix} \text{N}=\text{CMe} \\ \text{NPh}\cdot\text{CMe} \end{matrix} \text{CH} + 2\text{H}_2\text{O}$ . Similar

results are obtained with benzil, except that the initial velocity of the reaction is somewhat less. With dipyrrolyl, although the phenylosazone is known, no reaction with phenylhydrazone occurs under the experimental conditions of the present investigation.

As regards terpenic ketones, camphor, bromocamphor, and

fenchone, which are bicyclic, are inert towards phenylhydrazine. The monocyclic pulegone, however, reacts completely, the molecular weight falling at approximately constant velocity to about 60% and then at gradually diminishing velocity to 52% of the theoretical value. Menthone behaves similarly to pulegone, with which, rather than with the other terpenic ketones examined, it presents structural analogies. Carvone is inactive towards phenylhydrazine, the double linking in the nucleus possibly favouring an enolic configuration. Santonin also is inactive.

The results obtained with aldehydes emphasise the promptitude with which the aldehydic function is exercised in presence of phenylhydrazine. The aldehydes investigated were dextrose, cuminaldehyde (isopropylbenzaldehyde), *o*-, *m*-, and *p*-nitrobenzaldehydes, phenylacetaldehyde, cinnamaldehyde, *m*-nitrocinnamaldehyde, vanillin, *p*-dimethylaminobenzaldehyde, furfuraldehyde, and phthalaldehyde. None of these remains inert towards phenylhydrazine, and most of them quickly precipitate the phenylhydrazones. Furfuraldehyde reacts instantly, but gives no precipitate. With phenylacetaldehyde, which also yields no precipitate, the reaction is somewhat slow in its final phase, this thus resembling the aliphatic aldehydes. Cinnamaldehyde and its *m*-nitro-derivative, on the other hand, exhibit towards phenylhydrazine the behaviour of an aromatic aldehyde, in spite of the fact that the aldehyde group lies in the side chain.

Dextrose furnishes no precipitate with phenylhydrazine, but the reaction proceeds with the regularity shown in the case of the aliphatic aldehydes, although the retarding influence of the alcoholic groups is manifest. Phthalaldehyde behaves abnormally, the value of the molecular weight in phenylhydrazine solution being only 23% of the value calculated from the amount of the aldehyde taken.

T. H. P.

**The Opening of the Lactone Ring of Phthalide Derivatives by Hydrazine.** J. TEPPEMA (*Rec. trav. chim.*, 1923, 42, 30-68).—The object of this work was to study the influence on the stability of the lactone ring in phthalide of substituents both in the benzene ring and in the methylene group of the lactone ring. The stability of the ring is gauged by the ability or otherwise of hydrazine to open the ring with formation of a benzhydrazide and further by the stability of aldehydo- and keto-derivatives of the benzhydrazide. The action of hydrazine on phthalide was studied by Wedel, who concluded that the product formed was the hydrazide of *o*-hydroxymethylbenzoic acid (A., 1900, i, 363), but Blaise and Luttringer concluded that the additive compound was formed at the keto-group without rupture of the lactone ring (A., 1905, i, 329). The results of the present work do not support the latter view. A number of derivatives of *o*-hydroxymethylbenzhydrazide with aldehydes and ketones were prepared.

*p*-Methoxybenzylidene-*o*-hydroxymethylbenzhydrazide,  
 $\text{OH}\cdot\text{CH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{NH}\cdot\text{N}\cdot\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{OMe},$

forms colourless needles, m. p. 165°. *iso*Propylidene-*o*-hydroxy-

*methylenbenzhydrazide* forms colourless spangles, m. p. 148°. A derivative could not be obtained with acetophenone. *d-Mannose-o-hydroxymethylbenzhydrazide* crystallises in colourless needles, m. p. 106–109°; in boiling aqueous solution it is decomposed by benzaldehyde with formation of benzylidene-*o*-hydroxymethylbenzhydrazide. *d-Galactose-o-hydroxymethylbenzhydrazide* was obtained in crystals, m. p. 70–75°, but could not be recrystallised unchanged. The corresponding dextrose derivative was obtained only as a syrup; it is decomposed by benzaldehyde in hot aqueous solution. An acetyl derivative of *o*-hydroxymethylbenzhydrazide can be obtained by the action of acetic anhydride in the cold. Its decomposition in the hot, with formation of phthalide, accounts for Wedel's failure to prepare it. The acetyl compound does not react with benzaldehyde and must therefore be a *N*-acetyl derivative. *N-Acetyl-o-hydroxymethylbenzhydrazide*,  $\text{OH}\cdot\text{CH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{NH}\cdot\text{NHAc}$ , forms colourless spangles, m. p. 146°. No benzoyl derivative of *o*-hydroxymethylbenzhydrazide could be obtained with benzoyl chloride.

The mono-nitro-derivative obtained by nitrating phthalide either with pure nitric acid or with a nitrate and sulphuric acid is 5-nitrophthalide, m. p. 143°, not 4-nitrophthalide as stated by Hoenig (A., 1886, 242). In the literature different methods of notation are adopted by different authors; the present author adopts the method shown in the annexed formula. 5-Nitro-2-hydroxymethylbenzhydrazide forms yellow needles, m. p. 167–168°. The isopropylidene derivative of this forms colourless needles, m. p. 165°; the benzylidene derivative forms colourless spangles, m. p. 167°.

The aldehyde and ketone derivatives of nitro-*o*-hydroxymethylbenzhydrazide are not hydrolysed so readily as those of *o*-hydroxymethylbenzhydrazide, with re-formation of the phthalide, and, conversely, the presence of the nitro-group facilitates the rupture of the lactone ring. *N-Acetyl-5-nitro-2-hydroxymethylbenzhydrazide* forms colourless spangles, m. p. 171°; when boiled with acetic anhydride, it is decomposed, forming 5-nitrophthalide.

5-Aminophthalide is best prepared by reducing 5-nitrophthalide with hydrogen sulphide in ammoniacal alcoholic solution. When reduced with phosphorus and hydrogen iodide, it gives an amino-*o*-toluic acid, m. p. 196°, not 153°, as stated by Hoenig. This was identified as 4-amino-*o*-toluic acid, which establishes the constitution of the above 5-nitrophthalide. 4-Amino-*o*-toluic acid was synthesised by a new method, through the steps 4-nitro-*o*-toluidine,  $\rightarrow$  4-nitro-2-cyanotoluene  $\rightarrow$  4-amino-2-cyanotoluene  $\rightarrow$  4-amino-*o*-toluic acid.

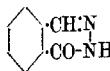

The lactone ring of 5-aminophthalide is opened by hydrazine with formation of 5-amino-2-hydroxymethylbenzhydrazide, colourless needles, m. p. 147°; benzylidene derivative, m. p. 161°; isopropylidene derivative, m. p. 170°. 5-Acetamidophthalide forms colourless needles, m. p. 222–223°. When 5-amino-2-hydroxymethylbenzhydrazide is treated with cold acetic anhydride, it forms the diacetyl derivative, 5-acetamido-2-hydroxymethylacetylbenzhydrazide,

small colourless needles, m. p. 195°; but with hot acetic anhydride, 5-acetamidophthalide is formed.

Contrary to the statement of Hoenig, 5-aminophthalide can be readily diazotised and transformed almost quantitatively into a halogen derivative by Sandmeyer's method. 5-Chlorophthalide forms colourless needles, m. p. 110°; 5-bromophthalide forms similar crystals, m. p. 98°. 5-Chloro-2-hydroxymethylbenzhydrazide forms colourless needles, m. p. 139°; benzylidene derivative, m. p. 165—166°; isopropylidene derivative, m. p. 153°; acetyl derivative, m. p. 160°. 5-Bromo-2-hydroxymethylbenzhydrazide forms colourless needles, m. p. 152°; benzylidene derivative, m. p. 171°; isopropylidene derivative, m. p. 157°; acetyl derivative, m. p. 153°.

The introduction of a single methyl, ethyl, or phenyl group into phthalide in the  $\alpha$ -position stabilises the lactone ring to such an extent that hydrazine cannot effect the rupture. A chloro-, bromo-, or nitro-group in the 5-position of  $\alpha$ -methylphthalide weakens the lactone ring sufficiently to permit rupture by hydrazine, but this is not the case with  $\alpha$ -ethylphthalide or  $\alpha$ -phenylphthalide. 5-Amino- $\alpha$ -ethyl- and 5-amino- $\alpha$ -methyl-phthalide do not react with hydrazine. The dialkyl and diphenylphthalides are extremely stable and their inactivity towards hydrazine is not affected by substituents in the 5-position.

$\alpha$ -Methylphthalide has  $n_D^{20}$  1.5450,  $d_4^{20}$  1.1601, m. p. 7°. 5-Nitro- $\alpha$ -methylphthalide, the principal nitration product of  $\alpha$ -methylphthalide, is accompanied by a small quantity of an isomeride, probably the 3-nitro-compound. With hydrazine, 5-nitro- $\alpha$ -methylphthalide gives 5-nitro-2- $\alpha$ -hydroxyethylbenzhydrazide,  $\text{CH}_3\cdot\text{CH}(\text{OH})\cdot\text{C}_6\text{H}_4(\text{NO}_2)\cdot\text{CO}\cdot\text{NH}\cdot\text{NH}_2$ , forming colourless needles, m. p. 120°. The isopropylidene derivative has m. p. 127°, but when recrystallised from alcohol partly decomposes with regeneration of the lactone. A benzylidene derivative could not be obtained on account of the formation of lactone. The lactone ring in 5-nitro- $\alpha$ -methylphthalide is therefore more stable than that in 5-nitrophthalide. 5-Nitro-2- $\alpha$ -hydroxyethyl-acetylbenzhydrazide, m. p. 126°, has similar properties to the other acetyl derivatives described. 5-Amino- $\alpha$ -methylphthalide does not react with hydrazine. From it were prepared 5-chloro- $\alpha$ -methylphthalide, colourless needles, m. p. 45°, and 5-bromo- $\alpha$ -methylphthalide, m. p. 59°. 5-Chloro-2- $\alpha$ -hydroxyethylbenzhydrazide forms colourless needles, m. p. 108°; its isopropylidene derivative has m. p. 119°. The 5-bromo-2- $\alpha$ -hydroxyethylbenzhydrazide has m. p. 119° and its isopropylidene derivative 135°. 5-Amino- $\alpha$ -ethylphthalide was obtained by reduction of the corresponding nitro-compound; it forms small, yellow needles, m. p. 140°. From this were obtained 5-chloro- $\alpha$ -ethylphthalide, colourless needles, m. p. 54°, and 5-bromo- $\alpha$ -ethylphthalide, similar crystals, m. p. 63°. By the action of hydrazine on  $\alpha$ -amino- or  $\alpha$ -bromo-phthalide, 1-keto-1:2-dihydrophthalazine (annexed formula) is obtained, and the same substance is formed from hydrazine and diphtalide ether, which thus behaves as the anhydride of phthalaldehydic acid. 5-Amino- $\alpha$ -dimethylphthalide cry-

tallises in colourless needles, m. p. 115°. With bromine, it gives 4:6-dibromo-5-amino- $\alpha$ -dimethylphthalide, colourless needles, m. p. 138°. 4:6-Dibromo-5-amino- $\alpha$ -diethylphthalide crystallises in spangles, m. p. 93°. Not one of these derivatives of a dialkylphthalide is acted on by hydrazine. The work serves to confirm and extend Hjelt's rule regarding the stability of lactone rings (A., 1891, 822).

**The Configuration of the Doubly-linked Tervalent Nitrogen Atom. The Resolution of the Pyridylhydrazones of cyclo-Hexylene Dithiocarbonate.** WILLIAM HOBSON MILLS and HANS SCHINDLER (T., 1923, 123, 312—323).

**The Ionisation of Protein Chlorides.** DAVID I. HITCHCOCK (J. Gen. Physiol., 1923, 5, 383—394).—By the use of the silver-silver chloride electrode and the hydrogen electrode, electrometric determinations have been made of the chloride and hydrogen-ion concentrations in solutions of proteins (gelatin, egg-albumin, casein, edestin, and serum-globulin) to which varying quantities of hydrochloric acid have been added. It is concluded that the hydrochlorides of these proteins are strongly ionised, and that there is no marked repression of the ionisation by excess of hydrochloric acid.  
W. O. K.

**Density of Albumin Solutions.** M. A. RAKUSIN and G. D. FLEISHER (Chem. Ztg., 1923, 47, 66).—A table is given of the density of albumin solutions at 17° up to a concentration of 15.35%, at which the solution is saturated. White of egg is a saturated solution of albumin. When freed from fat and clarified by treatment with lead acetate, albumin has a considerably lower density than the crude substance, the value for a 5% solution being  $d_{15}^{15}$  1.01288 for the pure substance and  $d_{15}^{15}$  1.01341 for the crude. The specific rotatory power is unchanged by the purifying process.  
H. C. R.

**The Nature of Nucleins.** S. NAKAGAWA (Z. physiol. Chem., 1923, 124, 274—277).—Hydrolysis of nucleoprotein by pepsin yields no nuclein. The idea of Steudel is confirmed that nucleoproteins are loose compounds of nucleic acid and a protein base.  
W. O. K.

**The Hydrolysis of Proteins by Strong Sulphuric Acid.** E. SALKOWSKI (Biochem. Z., 1922, 133, 1—20).—Horn, on complete hydrolysis by three times its weight of 73.6% sulphuric acid, gives practically no humin material. The hydrolysate reduces Fehling's solution to an extent which indicates the presence of 13% of apparent sugar. Pyruvic acid, aldehydes of the aliphatic series, and furfuraldehyde are also present.  
W. O. K.

**Heteroalbumose.** E. ZUNZ and P. GYÖRGY (Bull. Acad. roy. Belg., 1914, 359—380).—An investigation of Pick's heteroalbumose (A., 1900, i, 68) by two methods: (1) Fractionation by Siegfried's method (A., 1906, i, 144) and (2) ultra-filtration, using collodion and acetic acid of three different concentrations. The authors

conclude that Pick's hetero-albumose is really a mixture. The chief constituent (insoluble in twice its bulk of 95% alcohol) is a heteroalbumose with  $[\alpha]_D^{25} -72.5^\circ$ , but associated with it are several protoalbumoses of low rotatory power and soluble in twice their bulk of alcohol. One of these is apparently responsible for the Adamkiewicz reaction given by some preparations of Pick's heteroalbumose. Altogether, fifteen different fractions of the latter are examined and compared with the original substance by means of elementary analysis, rotatory power, gold numbers, refractive indices, etc. E. E. T.

**Bioluminescence. XV. Electro-reduction of Oxy-luciferin.** E. NEWTON HARVEY (*J. Gen. Physiol.*, 1923, 5, 275-284).—If a solution containing luciferin and luciferase and some sodium chloride is electrolysed, the oxy-luciferin is reduced at the cathode by the nascent hydrogen, and as it is oxidised back again in the presence of the luciferase, by the oxygen dissolved in the water, with the production of light, there is immediately luminescence. Similar reduction by nascent hydrogen also takes place at the surface of metals (aluminium, manganese, zinc, and cadmium) when these are immersed in water containing oxy-luciferin, although there is no actual production of molecular hydrogen. Other systems are described where electrochemical reduction of luciferin occurs. In general, the production of light by the combination oxy-luciferin-luciferase is a very good test for nascent hydrogen. Molecular hydrogen does not produce luminescence. If, however, a palladiumised surface be introduced, it becomes strongly luminescent, as it activates the hydrogen. W. O. K.

**The Mechanism of the Effect of Acids and Alkalis on the Digestion of Proteins by Pepsin or Trypsin. A Correction.** JOHN H. NORTHROP (*J. Gen. Physiol.*, 1923, 5, 415; cf. this vol., i, 69).—A statement made in the previous paper (*loc. cit.*) to the effect that the amount of acid required to bring protein solution to a given  $P_H$  is independent of the nature and valency of the anion is true only of strong acids. W. O. K.

**Influence of Reaction on the Activity of Trypsin. II.** W. E. RINGER (*Z. physiol. Chem.*, 1923, 124, 171-193; cf. A., 1922, i, 282).—The solution of fibrin by trypsin is inhibited by sulphates, thiocyanates, and ferrocyanides, but more strongly by multivalent cations such as calcium, which also strongly inhibit the swelling of fibrin in water. The effects, however, are not quite analogous; bile salts, for example, completely inhibit the solution of fibrin at concentrations at which the effect on the swelling is quite inappreciable. Salts with multivalent cations affect the viscosity of alkaline protein solutions (dialysed serum). The effect of these salts on the tryptic hydrolysis of such solutions is at first one of inhibition, but this very soon disappears. Experiments confirm the fact that alkaline protein solutions show a gradual increase in internal friction and that after a long time the internal friction again becomes less. W. O. K.

**Equilibrium between the so-called "Antitrypsin" of the Blood and Trypsin.** RAYMOND G. HUSSEY and JOHN H. NORTROP (*J. Gen. Physiol.*, 1923, 5, 335—351).—From a study of the inhibition of trypsin by blood plasma, it is concluded that the effect is not one of adsorption, but that it is more probably chemical in nature. It is shown that if the assumption is made that an easily dissociated compound of the trypsin and the inhibiting substance is formed, the law of mass action is obeyed according to the equation  $[\text{Trypsin}][\text{inhibiting substance}]/[\text{Compound of Trypsin and inhibiting substance}] = K$ . Equilibrium is attained very quickly and is reversible, and this fact opposes the view that there is an adsorption. Quantitative experiments have been carried out by the authors' method on (1) the effect of adding varying amounts of plasma to a constant amount of trypsin, (2) the effect of adding varying amounts of trypsin to a constant amount of plasma, and (3) the effect of dilution on a plasma-trypsin mixture, and the results accord with the theory that a reversible equilibrium is attained. These conclusions are in harmony with the results that have been obtained with other enzymes.

W. O. K.

**Invertase.** A. FODOR (*Z. physiol. Chem.*, 1923, 124, 278—281).—Criticism of the results of Willstätter, Graser, and Kuhn (A., 1922, i, 1200), pointing out the difficulty of being certain of the purity of the preparations obtained.

W. O. K.

**Kinetic Researches on Saccharase.** H. VON EULER and K. MYRBÄCK (*Z. physiol. Chem.*, 1923, 124, 159—170).—The unimolecular reaction constant  $k$  is determined for the inversion of sucrose by saccharase (invertase), from the expression  $k = 1/t \cdot \log a/(a-x)$ , where  $x$  is the amount of sucrose inverted in a time  $t$  out of the initial amount  $a$ . With increasing values of  $c$ , the initial concentration of the sucrose, the value of the product  $kc$  increases until  $c$  is about 4 g. per 100 c.c., after which it is constant until  $c$  is about 20 g. per 100 c.c., and then it decreases. If, on the assumption that a reversible equilibrium is reached between enzyme and substrate, the constant  $K = [\text{Enzyme}][\text{Substrate}]/[\text{Enzyme Substrate}]$  is calculated, which is possible if it be also assumed that all the enzyme is combined with the substrate when  $k$  is maximal, it is found to vary from 0.027 to 0.0175.

W. O. K.

**Influence of Amino-acid in Protecting Amylase from Inactivation by Mercury.** H. C. SHERMAN and MARY L. CALDWELL (*J. Amer. Chem. Soc.*, 1922, 44, 2923—2926).—Glycine and phenylalanine and presumably other amino-acids protect against small concentrations of mercuric chloride added when testing the activity of purified pancreatic amylase and allow the latter to act almost as efficiently as if no mercury were present. The minute amounts of mercury which might conceivably have been present in the histidine and tryptophan preparations used could not, therefore, account for their entire lack of activating influence on

the amylolytic action of the enzyme as previously recorded (A., 1922, i, 283). W. G.

**Influence of Lysine on the Hydrolysis of Starch by Purified Pancreatic Amylase.** H. C. SHERMAN and MARY L. CALDWELL (*J. Amer. Chem. Soc.*, 1922, 44, 2926—2930).—Lysine has no effect on the amylolytic action of pancreatic amylase, but exerts a favourable influence on its saccharogenic action. Accepting the view that the enzyme (pancreatic amylase) is essentially a protein substance which gradually becomes inactivated through hydrolysis in the aqueous medium in which it acts, and that the apparent activating influence of amino-acids is due to retardation of this hydrolysis of the enzyme, it is suggested that the lysine in the enzyme molecule is not split off until after the stage of amylolytic action has passed, but is only concerned in the later stages represented by saccharogenic activity. These observations confirm and extend the theory advanced to explain the effect of histidine and tryptophan on the same enzyme (A., 1922, i, 283). W. G.

**Influence of some Organic Compounds upon the Hydrolysis of Starch by Salivary and Pancreatic Amylases.** H. C. SHERMAN and NELLIE M. NAYLOR (*J. Amer. Chem. Soc.*, 1922, 44, 2957—2966).—The authors consider that the favourable effect reported by Rockwood (A., 1917, i, 358; 1918, i, 86, 274) to be exerted by several types of organic compounds on the activity of amylolytic enzymes was due in most, if not in all, cases, other than those of natural amino-acids, to hydrogen-ion or salt effects, rather than to the organic structure of the compounds. In the presence of favourable concentrations of chloride-, phosphate-, and hydrogen-ions, no favourable effect on the activity of the enzyme was shown by methyl- and ethyl-amine hydrochlorides, aniline sulphate, benzoic acid, benzamide, anthranilic acid, or hippuric acid. Previous results as to the favourable influence of several amino-acids resulting from protein hydrolysis have been confirmed and extended. This influence may be attributed either to a direct activating effect dependent on the structural nature of these substances as  $\alpha$ -amino-acids or to conservation of the enzyme by retarding its hydrolysis, but the results with hippuric acid fail to confirm the activation hypothesis. W. G.

**Some Actions of Thorium-X on Diastases and Micro-organisms.** J. P. AVERSENQ, L. JALOUSTRE, and E. MAURIN (*Compt. rend.*, 1923, 176, 193—195).—Thorium-X, at the concentrations used, activates in a marked manner the hydrolysing and oxidising enzymes studied, the increased action in a given time being of the order of 30%. Similarly, relatively small amounts of thorium-X were capable of increasing the vitality of certain pathogenic organisms and of certain living cells. W. G.

**Peroxydase.** III. RICHARD WILLSTÄTTER and ADOLF POL-LINGER (*Annalen*, 1923, 430, 269—319).—In continuation of previous work (A., 1918, i, 555) on the purification of peroxydase

preparations, the authors have made a detailed study of the influence of adsorption on and subsequent elution from alumina and kaolin, and of precipitation by tannic acid, on the activity of peroxydase solutions. On the basis of these experiments, two methods of purification are worked out in detail, the results of each operation being followed by determinations of the "purpurogallin number" (*loc. cit.*). According to one method, the peroxydase in a solution having a purpurogallin number 302 is first adsorbed on alumina suspended in 50% alcohol, removed in carbonic acid solution, and then again adsorbed on alumina in dilute alcohol. One further adsorption on kaolin in 50% alcohol and three subsequent adsorptions on alumina raise the purpurogallin number to 1900, the highest value as yet observed. According to the second method, the peroxydase is subjected to four adsorptions on alumina in 50% alcohol and three on kaolin in 0.02N-acetic acid, and a precipitation by tannin, the final purpurogallin number being 3070.

The question as to whether iron enters into the constitution of peroxydase cannot be conclusively settled on the analytical data, because, although for a given natural source and method of purification the iron content runs roughly parallel with the purpurogallin number, a change either in the source or the process affects the proportion of iron in a way which cannot at present be simply accounted for.

C. K. I.

**Reductases. II. Comparison of the Influence of Alkalis on Potato Reductase.** I. A. SMORODINCEV (*Z. physiol. Chem.*, 1923, 124, 202—210; cf. A., 1922, i, 1201).—The effect of alkali on the reductase in potatoes (nitrase) is to inhibit the activity, an effect apparently independent of the kation, and due to the hydroxyl-ion concentration.

W. O. K.

**Mode of Action of Vitamins.** ANTONIO DE GREGORIO ROCASOLANO (*Anal. Fis. Quim.*, 1922, 20, 433—436).—Theoretical. The vitamins are held to act as colloidal catalysts.

G. W. R.

**Vitamins-B and -D.** CASIMIR FUNK and JULIA B. PATON (*J. Metabolic Research*, 1922, 1, 737—775).—Vitamin-B is destroyed by alkali and also by heating in an autoclave under pressure for three hours; the effect of such treatment on vitamin-D is much smaller. When grown in a solution containing both vitamins, yeast or other fungi removes the latter, which is retained tenaciously by the yeast-cells.

CHEMICAL ABSTRACTS.

**An Attempt to Resolve Quaternary Phosphonium Compounds.** L. G. RADCLIFFE and W. H. BRINDLEY (*Chemistry and Industry*, 1922, 42, 64—66).—In the hope of effecting a resolution of a quaternary phosphonium compound, *phenyl-p-tolylmethyl-allylphosphonium d-bromocamphorsulphonate* was prepared, but attempts to crystallise it failed; it was only obtained as a jelly-like mass, finally becoming resinous. The synthesis of the compound was accomplished from *p*-tolylidichlorophosphine, through *phenyl-p-tolylchlorophosphine* to *phenyl-p-tolylmethylphosphine*,

which was then combined with allyl iodide. The final yield was very small. Attempts to prepare phenyl-*p*-tolylethyl-*n*-butylphosphonium iodide from phenyl-*p*-tolylethylphosphine and *n*-butyl iodide led only to the formation of an uncrystallisable oil.

E. H. R.

**Additive Reactions of Phosphorus Halides. VI. The 1:2- and 1:4-Addition of Diphenylchlorophosphine.** J. B. CONANT, J. B. S. BRAVERMAN, and R. E. HUSSEY (*J. Amer. Chem. Soc.*, 1923, **45**, 165—171; cf. A., 1921, i, 69).—Diphenylchlorophosphine reacts with benzaldehyde and phenyl styryl ketone in the presence of glacial acetic acid, giving, respectively, an hydroxy- and a keto-phosphine oxide. By using acetic anhydride in place of the acid, the mechanism of the reaction with the unsaturated ketone has been established. Under these conditions, an un-

saturated intermediate compound,  $O(PPh_2 \begin{smallmatrix} \diagup O-CPh \\ \diagdown CHPh \end{smallmatrix} \diagup CH)_2$ , is formed, but could not be isolated in a crystalline state. On treatment with water, it gives the ketophosphine oxide, and it readily combines with two equivalents of bromine to yield a dibromide without the evolution of hydrogen bromide. This dibromide, not isolated as such, on treatment with water gives a mixture of two isomeric monobromoketophosphine oxides, one of which can be obtained by direct bromination of the ketophosphine oxide itself. These two monobromo-derivatives behave differently towards alcoholic sodium hydroxide. The one with the high m. p. loses hydrogen bromide to give an unsaturated ketophosphine oxide, whilst the other is reduced to the ketophosphine oxide. On the other hand, by boiling it with potassium acetate in methyl alcohol, the bromo-compound with the high m. p. is reduced to the ketophosphine oxide.

The following compounds are described. *Diphenyl- $\alpha$ -hydroxybenzylphosphine oxide*, m. p. 230°, obtained from benzaldehyde and diphenylchlorophosphine. *Diphenyl- $\beta$ -benzoyl- $\alpha$ -phenylethylphosphine oxide*, m. p. 227°, similarly obtained from phenyl styryl ketone. *Diphenyl- $\beta$ -*p*-chlorobenzoyl- $\alpha$ -phenylethylphosphine oxide*, m. p. 225—226°. *Diphenyl- $\beta$ -bromo- $\beta$ -benzoyl- $\alpha$ -phenylethylphosphine oxide*, in two isomeric forms, m. p. 187° and 158°, respectively. *Diphenyl- $\beta$ -bromo- $\beta$ -*p*-chlorobenzoyl- $\alpha$ -phenylethylphosphine oxide*, in two isomeric forms, m. p. 196° and 187°, respectively. *Diphenyl- $\beta$ -benzoyl- $\alpha$ -phenylvinylphosphine oxide*, m. p. 143°; and *diphenyl- $\beta$ -*p*-chlorobenzoyl- $\alpha$ -phenylvinylphosphine oxide*, m. p. 151°.

W. G.

**Tetraphenyldiarsine.** PARRY BORGSTROM and MARGARET M. DEWAR (*J. Amer. Chem. Soc.*, 1922, **44**, 2915—2923).—An extension of previous work (A., 1920, i, 196). When tetraphenyldiarsine is prepared in a pure state, out of contact with air, its m. p. is 130—130.5° (corr.) (cf. Michaelis and Schulte, A., 1883, 187). Quantitative data are given for its oxidation in moist air and for its absorption of iodine, which latter decreases with the

age of the solution. This decrease in iodine absorption corresponds with an increase in molecular weight as determined cryoscopically in naphthalene as solvent. The specific conductivity in liquid sulphur dioxide increases with the age of the solution, changing from  $13.3 \times 10^{-6}$  to  $100 \times 10^{-6}$  mhos in nineteen days. The conductivity also increases with rise in temperature. The data indicate that the bond between the arsenic atoms of the tetraphenyldiarsine is easily broken. Bivalent arsenic of the type  $\text{Ph}_2\text{As}$  may be present transitorily in solution, but it is doubtful if it is the stable form. The valency or configuration of the stable form is not known.

Tetraphenyldiarsine reacts with methyl iodide, forming dimethyldiphenylarsonium iodide (cf. Steinkopf and Schwen, A., 1921, i, 694).  
W. G.

**Some Determinations of Molecular Weight in the Arsinic Acid Series.** RICHARD LORENZ and ELISABETH BREEHER (*Ber.*, 1923, 56, [B], 174—176; cf. Lorenz and Schmidt, A., 1920, i, 777, 897; ii, 465).—The molecular weights of arsanilic, *o*-toluidino-, resorcinic-, 3-nitro-4-aminophenyl-, 3-nitro-4-hydroxyphenyl-, 3-nitrophenyl-, *p*-phenylenedi-, and *o*-phenylenediamine-arsinic acids have been estimated in aqueous solution by the ebullioscopic method. They appear generally to have the simple, non-polymerised structure of the type  $\left[ \text{Ph} \cdot \text{AsO} \begin{smallmatrix} \text{O} \\ \text{H} \end{smallmatrix} \right]_{\text{H}}$ . *o*-Phenylenediaminearsinic acid, however, is polymerised to such an extent that it may exhibit double the normal molecular weight, but different preparations give different values.

Arsanilic acid,  $(\text{NH}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{AsO}_2)_2\text{H}_2$ , is strictly monobasic, and is preferably represented as an internal salt,

Similar observations are recorded with *o*-toluidinoarsinic acid, *p*-dimethylaminophenylarsinic acid, and *o*-phenylenediaminearsinic acid. Resorcinic-, 3-nitro-4-aminophenyl-, dichlorophenyl-, dibromophenyl-, 3-nitro-4-hydroxyphenyl-, *p*-iodophenyl-arsinic acids, and 4-amino-3-carboxyphenyl-arsine oxide behave normally with regard to electrical conductivity and exhibit normal molecular weights.  
H. W.

**Preparation of Mercury Dibenzyl.** A. GARCIA BANÚS (*Anal. Fis. Quím.*, 1922, 20, 667—668).—Mercury dibenzyl is prepared by treating benzyl chloride with excess of magnesium dust and adding mercuric chloride to the liquid, after decanting from excess of magnesium. The mixture is heated with frequent shaking under a reflux apparatus. Dilute acetic acid is added, and mercury dibenzyl is obtained by crystallisation from the ethereal solution. It has m. p. 110—111°.  
G. W. R.

### Physiological Chemistry.

**The Importance of Amides in Plant Feeding-stuffs.** F. HONCAMP (*Z. angew. Chem.*, 1923, 36, 45—49).—It is shown that urea may, at least partly, replace protein in feeding-stuffs without any injury to the animal. A. G. P.

**The Possibility of Urea as a Source of Protein in Ruminants. The Excretory Function of the Skin.** ARTHUR SCHEUNERT, WILHELM KLEIN, and MARIA STEUBER (*Biochem. Z.*, 1922, 133, 137—191).—From experiments in which urea was administered to animals as the source of nitrogen, it has been found impossible to demonstrate that it can function as a source of protein. W. O. K.

**The Measurement of Buffering.** GÜNTHER LEHMANN (*Biochem. Z.*, 1922, 133, 30—45).—A valuable measure of the buffering of a solution is given by  $b/(P_{H_1}-P_{H_2})$  where  $P_{H_1}$  is measured before and  $P_{H_2}$  after the addition to 10 c.c. of the buffer solution of a small quantity  $b$  of hydrochloric acid (or sodium hydroxide) measured in c.c. of 0.01N-solution. The  $P_H$  values are conveniently determined colorimetrically. Examples are given, chiefly of liquids of physiological importance. Values above 8 indicate strong buffering, 0.5—4, weak buffering, and below 0.5 no buffering. Blood gives a value of about 11. W. O. K.

**Comparative Buffering Value of American Peptones.** J. BRONFENBRENNER, G. G. DE BORD, and P. F. ORR (*Proc. Soc. Exp. Biol. Med.*, 1921, 19, 16).—The  $p_H$  of the various peptone solutions was determined electrometrically before and after the addition of measured amounts of acid and alkali, respectively. The initial reactions of the different solutions varied greatly; so did their buffer actions at a given  $p_H$ , some being 5 times greater than others. The buffering effect varied at different zones of  $p_H$ , being most marked between  $p_H$  9 and 8, and least between  $p_H$  5 and 4. For a given peptone the buffering varied at different  $p_H$  zones; the absolute concentration of buffer salts was highest at the lowest  $p_H$  and not at neutrality or high  $p_H$  as would be most desirable in media for use in the identification of bacteria by cultural methods. CHEMICAL ABSTRACTS.

**Antiketogenesis.** A. I. RINGER (*Proc. Soc. Exp. Biol. Med.*, 1921, 19, 97—99).—Glyceraldehyde, dihydroxyacetone, pyruvaldehyde, and pyruvic and lactic acids, when fed to diabetic animals, are completely and directly converted into dextrose and excreted in the urine, whilst acetaldehyde and possibly ethyl alcohol possess antiketogenetic properties. CHEMICAL ABSTRACTS.

**Chemical Researches on Nuclear Staining.** H. STEUDEL and SHUNGO OSATO (*Z. physiol. Chem.*, 1923, 124, 227—246).—It is considered probable that, in nuclear staining, a chemical

reaction takes place of the type: clupein nucleate+hydrochloride of the dye  $\rightarrow$  nucleate of the dye+clupein hydrochloride. By measuring the crystal violet absorbed from solutions of various strengths by heads of spermatozoa, it is shown that, if this assumption be true, the reaction does not proceed to completion, but that probably an equilibrium is set up. Similar results are obtained with protamine nucleic acid, with the nuclei of goose erythrocytes, with thymus leucocytes, and with nucleohiston, and also with other dyes—methylene-blue and eosin. W. O. K.

**The Nitrogenous Compounds Extracted from Testicles of the Ox.** KIYOSHI MORINAKA (*Z. physiol. Chem.*, 1923, 124, 259—266).—In an extract of ox testicles the following compounds have been identified: creatine, adenine, xanthine, arginine, histidine, choline, inositol, and probably guanine and hypoxanthine. W. O. K.

**The Maximal Quantity of the Glycogen Reserve in the Livers of Dogs of Different Ages.** (MMR) Z. GRUZEWSKA and E. FAURÉ-FRÉMIET (*Compt. rend.*, 1922, 175, 1237—1240; cf. A., 1921, i, 699).—Dogs were fed on a special diet and the liver and muscles analysed in order to determine the time during which the accumulated reserve of glycogen could remain unused in the liver. The conclusions are drawn that prolonged over-feeding was only tolerated by the liver in the case of a young and vigorous animal, and that the glycogenic function of the hepatic cell undergoes some modification either with age or with unfavourable circumstances without any apparent change in histological aspect. Further, in order to find the maximum glycogen content in the liver of a dog kept on an appropriate diet, the analysis must be carried out before the animal has attained its original weight as measured before fasting. H. J. E.

**Auto-oxidation and Anti-oxygen Action.** IV. CHARLES MOUREU and CHARLES DUFRAISSE (*Anal. Fis. Quim.*, 1922, 20, 383—393; cf. A., 1922, i, 250, 824).—A discussion of the general significance of auto-oxidation and anti-oxygen action in biology. The mechanism of the auto-oxidation of acetaldehyde and its inhibition by anti-oxygens is also discussed. It is supposed that acetaldehyde exists in two forms, one of which is very reactive and auto-oxidisable. The effect of an anti-oxygen is to catalyse the transformation of the reactive into the non-reactive form.

G. W. R.

**Isolation of the Thyroid Hormone.** BENNO ROMEIS (*Biochem. Z.*, 1922, 133, 97—111).—Thyroid gland is hydrolysed by boiling with a solution of barium hydroxide for five to six days, so that the biuret test disappears. The precipitate formed on acidifying with hydrochloric or acetic acid is purified by dissolving in dilute alkali, and reprecipitating several times by acidifying. The precipitate is extracted with 90% alcohol containing acetic acid, and on evaporating the alcohol, a precipitate separates, which is again submitted to the process of extraction by alcohol

containing acetic acid and by precipitation. This is repeated several times, and the resulting material is washed with ethyl ether and with light petroleum, and then consists of a very light brown powder, with a high iodine content. This substance resembles Kendall's thyroxin, to which it appears to be closely related. It is possibly even more active physiologically. W. O. K.

**Energy Exchanges in Muscle.** OTTO MEYERHOF (*Plüger's Archiv*, 1922, 195, 22—74; from *Chem. Zentr.*, 1922, iii, 1235—1236; cf. A., 1922, i, 897).—An investigation into the origin of the approximately 400 cal. liberated in the formation of 1 g. of lactic acid from glycogen (caloric quotient of lactic acid). The heat of combustion of lactic acid, estimated by way of zinc lactate, is 325,700 cal. per mol. The average caloric quotient of lactic acid with electrical stimulation is 370 cal. With cut muscle in a phosphate solution, the value is only 200 cal.; this is in fair agreement with the value calculated from the heat of decomposition of glycogen, the heat of dilution of lactic acid, and the heat of reaction with the phosphate. The extent to which lactic acid goes into solution influences the amount of heat developed. The heat of reaction of lactic acid with substances in intact muscle is affected by hydrogen-ion concentration. The difference between the heat of reaction of lactic acid in muscle (190—200 cal.) and with buffered solutions of amino-acids (130 cal.) or protein solutions (137—140 cal.) is attributed to changes in the state of ionisation of proteins in a non-aqueous phase. The temperature coefficient of lactic acid (per 10°) in cut muscle is 2—3, in intact muscle about 4. G. W. R.

**The Influence of Cooling on the Creatine in Muscle.** ALEXANDER PALLADIN and ANNA KUDERJAVZEV (*Biochem. Z.*, 1922, 133, 89—96).—There is a marked increase of creatine in the muscles of a rabbit if it is killed several hours after its body temperature has been reduced from 39° to about 30° by immersion for some time in a cold bath. This increase, of the order of 0.1%, reaches a maximum about twelve hours after the cooling, and there follows a slow return to normal. W. O. K.

**The Decomposition of Carbohydrates in Transversely Striped Muscles. III.** FRITZ LAQUER and PAUL MEYER (*Z. physiol. Chem.*, 1923, 124, 211—226; cf. A., 1922, i, 1089).—The effect of fresh frog's muscle in converting various carbohydrates into lactic acid has been investigated. The greatest activity is shown when acting on glycogen, followed by levulose, starch, dextrose, and mannose. All the other carbohydrates tested, galactose, sorbose, sucrose, maltose, diamylose, and tetramylose (obtained from starch by the action of *Bacillus macerans*), inulin and Merck's "Karamose" give insignificant yields of lactic acid. Thus if there is a reactive form of carbohydrate present in glycogen as previously suggested (*loc. cit.*), it does not appear to be any of the above. W. O. K.

**The Effect of Histozyum on the Homologues of Hippuric Acid.** I. A. SMORODINCEV (*Z. physiol. Chem.*, 1923, 124, 123—139).—Histozyum, which effects the hydrolysis of hippuric acid, appears in the kidneys and skeletal muscles of dogs and also markedly in the kidneys of pigs. It is also present in the spleen, lungs, heart, and skeletal muscles of dogs, but not in the liver, and is found in the liver of calves, oxen, and horses. It is almost insoluble in water and in aqueous glycerol. Besides hippuric acid, histozyum hydrolyses also *d*- $\alpha$ -benzamidobutyric acid and *l*-benzoyl-leucine, but not  $\beta$ -benzoylalanine, *dl*- $\beta$ -benzamidobutyric acid, benzamidoisobutyric acid, and *l*- $\beta$ -benzamidobutyric acid. Glycocholic acid and taurocholic acid are hydrolysed with the separation of cholic acid.

W. O. K.

**Faulty Diet and its Relation to the Structure of Bone.** P. G. SHIPLEY (*J. Amer. Med. Assoc.*, 1922, 79, 1563).—Among the dietetic principles concerned in the growth of bone are: (1) an uncharacterised organic substance, distinct from fat-soluble vitamin-*A*, and found in certain fish liver oils and in small amounts in butter and coconut oil, (2) calcium, (3) phosphorus, (4) water-soluble vitamin-*B*, (5) fat-soluble vitamin-*A*. Water-soluble vitamin-*C* influences the structure of the bone of the guinea pig, but not of the rat. Inadequacy of fat-soluble vitamin-*A* causes perfect calcification, but a high degree of osteoporosis develops; deficiency of water-soluble vitamin-*B* causes similar results. If the organic substance so abundantly present in fish oils is freely supplied, rickets will not develop in spite of a faulty ratio of calcium to phosphorus in the food. It is found that the shorter ultra-violet rays have an important antirachitic effect.

CHEMICAL ABSTRACTS.

**Decalcification of Teeth and Bones, and Regeneration of Bone through Diet.** P. R. HOWE (*J. Amer. Med. Assoc.*, 1922, 79, 1565—1567).—The magnesium content of sound teeth, when estimated by Tisdall and Kramer's method (*A.*, 1921, ii, 655), was found to range from 0.554 to 0.764% (average 0.649%), whilst decayed teeth contained 0.825 to 1.585% (average 1.154%). With all the proper food factors supplied except the antiscorbutic, the animal organism appears to withdraw calcium from the teeth and from some parts of the bone.

CHEMICAL ABSTRACTS.

**Tin in the Human Organism.** ÉMILE MISK (*Compt. rend.*, 1923, 176, 138—141).—Tin may be estimated in human organs by two methods. In the first, 100 g. of the pulped material and 1 g. of calcined magnesia are evaporated with 30 c.c. of 30% magnesium nitrate and the residue after drying at 250° is ignited at a dull red heat to a white ash, which is then fused with 2—3 g. of potassium hydroxide. The cold mass is extracted with water, and after filtration the filtrate is evaporated and the residue treated with nitric acid and the tin weighed as stannic oxide. In the second method, 100 g. of the material are evaporated with

50 c.c. of 30% potassium hydroxide and the residue heated to fusion, the cold mass then being treated as described above.

Tin exists normally in the human organism, and the liver has highest content, being followed by the stomach, kidneys, lungs, and brain. 0.03—0.04 g. of tin in 100 g. of human viscera is not excessive in amount. W. G.

**Glycogen Content of certain Invertebrates and Fishes.** L. G. KILBORN and J. J. R. MACLEOD (*Quart. J. Exp. Physiol.*, 1920, 12, 317—330).—By Pflüger's method, the following percentages of glycogen were found in the (moist) digestive glands (hepatopancreas): Asteroidea, 0.232 to 1.52; Lamellibranchiata, 0.31 to 1.56; Crustacea, 0.05 to 1.39; Elasmobranchii, 0.0 to 0.21; Teleostomi, 0.0 to 6.5. Feeding conditions and season seem partly responsible for the varying amounts. In the (moist) muscles the following percentages of glycogen were found: Lamellibranchiata, 0.077 to 2.67 (the latter in the adductor muscles); Crustacea, trace to 0.36; Elasmobranchii, 0.0 to 0.018; Teleostomi, 0.0 to 0.29. In all cases when it was possible to obtain a sufficient amount of heart muscle, the glycogen content was found to be several times greater than that of other muscles, and sometimes greater than that of the liver; thus in the lobster 0.85—1.42% was found in the heart muscle, while the other muscle content was 0.36%. In several cases, the glycogen was found to yield a sugar fermentable by yeast after hydrolysis. In other cases, part of the reducing material seemed to consist of other substances.

#### CHEMICAL ABSTRACTS.

**Concentration of Urea in Saliva.** P. S. HENCH and MARTHA ALDRICH (*J. Amer. Med. Assoc.*, 1922, 79, 1409—1412).—The combined urea- and ammonia-nitrogen values of the saliva are normally between 6 and 13 mg. per 100 c.c. These combined values closely approximate to those of the urea-nitrogen in the blood. In urea retention, the combined urea- and ammonia-nitrogen always increase with an increase in the blood urea-nitrogen.

#### CHEMICAL ABSTRACTS.

**Effect of Magnesium Sulphate on the Secretion of Bile.** EMMETT B. FRAZER (*J. Amer. Med. Assoc.*, 1922, 79, 1594—1596).—When introduced directly into the duodenum, or into the circulation, magnesium sulphate does not cause any change in the character of the bile, although in some instances the rate of flow was retarded.

#### CHEMICAL ABSTRACTS.

**The Solubility of Gallstones.** ANNE ROSIN (*Z. physiol. Chem.*, 1923, 124, 282—286).—Cholesterol gallstones are soluble to some extent in solutions of salts of bile acids, more particularly in solutions of sodium deoxycholate. W. O. K.

**The Excretion of Uric Acid on a Diet Poor in Purines.** H. STEUDEL (*Z. physiol. Chem.*, 1923, 124, 267—273).—The endogenous uric acid in the urine depends on the condition of the contents of the intestine. The urine of an individual whose faeces

showed fermenting powers was abnormally poor in uric acid, this being due apparently to destruction of the purine substances in the intestine.

W. O. K.

**The Rôle of the Effect of Acids in the Production of Adrenalin Hyperglycæmia.** F. KORNFELD and H. ELIAS (*Biochem. Z.*, 1922, 133, 192—211).—After the injection of adrenalin into rabbits, dogs, or human beings, there is only a very slight lowering of the carbon dioxide tension of the blood or in the case of men of the alveolar carbon dioxide tension (sometimes even this slight lowering is absent), but nevertheless there is marked hyperglycæmia. There is therefore no reason to believe that the hyperglycæmia is in any way due to the hypokapnia. W. O. K.

**The Formation of Conjugated Glycuronic Acids after Administration of Elbon.** KIVOSHI MORINAKA (*Z. physiol. Chem.*, 1923, 124, 247—252).—The urine of rabbits to which have been given by the mouth 2 g. of elbon (cinnamoyl-*p*-hydroxyphenylcarbamide) per day for a long time contains hippuric acid and also a levorotatory substance, isolated as the potassium salt, orange, colourless prisms, shown to be the potassium salt of *p*-hydroxyphenylcarbamideglycuronate, m. p. 231°, decomp.,  $[\alpha]_D^{20} -74.99^\circ$  in water. On hydrolysis with acid, glycuronic acid and *p*-aminophenol are obtained, the latter derived by the further hydrolysis of the *p*-hydroxyphenylcarbamide formed initially. W. O. K.

**[Physiological Action of Dialkyl- and Alkylaryl-barbituric acids.]** H. A. SHONLE and A. MOMENT (*J. Amer. Chem. Soc.*, 1923, 45, 243—249).—See this vol., i, 248.

**Comparative Toxicity of Different Acids towards Fish Sticklebacks.** (MILÉ) FRANCE GUEYLARD and MARCEL DUVAL (*Compt. rend.*, 1922, 175, 1243—1245).—In order to study the influence of acids on aquatic animals and to ascertain whether any toxic effect could be attributed solely to hydrogen-ion concentration, sticklebacks (*Gasterosteus aculeatus* var. *leirurus*) were placed in a series of solutions of acetic, lactic, propionic, and phosphoric acids of different hydrogen-ion concentration and the time of survival was noted. A diagram is given showing the curve obtained for each acid on plotting its  $p_H$  value against survival time in hours. The latter varies considerably with the  $p_H$  value, increasing slowly at first and then very rapidly with diminution in the concentration of hydrogen-ions, but the nature of the acids exerts considerable influence. For example, when  $p_H = 4$ , the fish live for more than eight hours in phosphoric acid, for one and a half hours in lactic acid, eleven minutes in acetic acid, and less than nine minutes in propionic acid.

H. J. E.

## Chemistry of Vegetable Physiology and Agriculture

**Activation of Hydrogen and Carbon Dioxide Assimilation by Bacteria.** W. RUHLAND (*Ber. Deut. bot. Ges.*, 1922, 40, 180—184).—The power of utilising the chemical energy of free hydrogen for carbon dioxide assimilation is widely distributed amongst bacteria. Contrary to opinions previously advanced that the carbon dioxide is first reduced by the activated hydrogen, a slow direct combustion of hydrogen occurs which furnishes the energy for the carbon dioxide reduction. This occurs, as with green plants, with the elimination of oxygen. Hidden by the hydrogen combustion, a slow exhalation of carbon dioxide occurs, involving the consumption of both free and combined oxygen. The presence of iron is essential for the assimilation, and it must be in combination as hydrogen carbonate. If carbon dioxide is excluded from the gaseous atmosphere of inorganic cultures, very little or no hydrogen is assimilated. The ratio of the volumes of hydrogen to oxygen consumed is in the youngest cultures less, but, later, greater than 2, the variation depending on the intensity of carbon dioxide exhalation. The maximum hydrogen assimilation occurs in weak alkaline solutions, and falls off rapidly on both sides to the respective limits of  $p_H=5.3$  and  $p_H=9.1$ . The protective action of many organic substances, for example, dextrose, against hydrogen assimilation is due to the rapid formation of acids to which they give rise, which causes the disappearance of the  $HCO_3^-$  ion, which alone can be assimilated. The utility of the hydrogen combustion expressed by the "economic quotient," Organic substance produced/Hydrogen and oxygen used, varies considerably, and is greatest in approximately neutral solution. With the same hydrogen-ion concentration and otherwise similar conditions, it is approximately proportional to the hydrogen and oxygen used up.  
G. F. M.

**The Microbic Metabolism of Lactic Acid and Pyruvic Acid.** E. AUBEL (*Compt. rend.*, 1923, 176, 332—335).—The author has isolated an organism from the Paris water supply which, when grown on a solution of dextrose and suitable mineral salts, produces during the first few days pyruvic acid and no lactic acid, but in the following days the pyruvic acid disappears and lactic acid makes its appearance. When the culture is on a similar medium, but the sugar is replaced by sodium pyruvate, the pyruvic acid slowly disappears and there is found in the medium acetic acid, an acid soluble in ether and giving the Hopkins reaction but only present in small amount, and a crystalline acid, m. p.  $152^\circ$ , not identified. When in the same medium the sodium pyruvate is replaced by calcium lactate, a portion of the lactic acid is converted into acetic acid and acetaldehyde, but pyruvic acid could not be detected.  
W. G.

**Growth and Respiration of Sulphur-oxidising Bacteria.**

SELMAN A. WAKSMAN and ROBERT L. STARKEY (*J. Gen. Physiol.*, 1923, 5, 285—310).—*Sulphomonas thio-oxidans* oxidises sulphur to sulphuric acid or sodium thiosulphate to sulphate, and at the same time absorbs atmospheric carbon dioxide as a source of carbon. The ratio between the sulphur oxidised and the carbon dioxide reduced is 31·8:1 and 64·2:1 in the cases of sulphur and thiosulphate, respectively. Excess of sulphur in the medium does not inhibit the oxidation, but nitrates have a strong inhibiting action. Dextrose is likewise innocuous, but peptone almost completely stops sulphur oxidation in 1% concentration. The injurious effect of acid becomes marked only at concentrations exceeding 0·5*N*. The optimum  $p_H$  for growth is between 2·0 and 5·5. The zone is sharply limited on the alkaline, but not on the acid side.

W. O. K.

**The Action of Saponin Substances on the Plant Cell.**

FRIEDRICH BOAS (*Ber. Deut. bot. Ges.*, 1922, 40, 249—253).—Cyclamin and digitonin in feeble concentration slightly increase the fermentative activity of the yeast-cell, in higher concentration they strongly retard it. This physiological action of these saponins is due to the formation of chemical compounds with the lipoids in the protoplasm, which are thereby inactivated, and the structure of the protoplasm is disturbed by the flocculation of the saponin-cholesteride. A slight modification of the lipid structure, insufficient to cause flocculation, increases the zymase activity, on the other hand, partly by increasing the permeability, and partly perhaps by removing retarding substances. Certain combinations of saponins such as quillaia saponin and digitonin are distinctly less poisonous than digitonin alone, and the combination digitonin-sodium glycine actually leads to increased zymase activity, which is to be attributed to the strong solvent action of the latter substance on lipoids, preventing the precipitation of the cholesterol and the consequent destruction of the cell-structure. No parallel could be traced between the surface activity and the chemical activity of the various saponins.

G. F. M.

**The Synthesis and Degradation of Asparagine in Plants.**

D. PRIANISCHNIKOV (*Ber. Deut. bot. Ges.*, 1922, 40, 242—248).—Whilst, as has already been shown, etiolated seedlings of Graminaceae and other plants can readily synthesise asparagine from ammonia presented in the form of a dilute solution of ammonium chloride or sulphate, and certain Leguminosae can effect the same synthesis only when calcium carbonate is also present, the yellow lupine showed under similar conditions a quite abnormal behaviour, no asparagine was formed, the normal asparagine content of the plant decreased, and the ammonia content became abnormally great, giving the cell juice an alkaline reaction. The presence of calcium carbonate only accentuated this phenomenon. This abnormal behaviour is entirely attributable to lack of carbohydrates, as on the one hand other plants were also shown to behave in this

abnormal way under an artificially created deficiency of carbohydrates, and on the other yellow lupine seedlings to which carbohydrates were supplied, either by utilising the green plants instead of etiolated plants for the experiments, or by feeding etiolated plants with dextrose solutions, behaved normally; that is to say, the asparagine-nitrogen increased, and the ammonia-nitrogen decreased. It follows, therefore, that it is not a peculiarity of the species but the conditions of nutrition which is the determining factor for the asparagine synthesis. Only when a carbohydrate or fatty carbon chain is present can the plant convert ammonia into asparagine and thence into amino-acids and proteins, otherwise ammonia accumulates, and the plants show the symptoms of ammonia poisoning. Asparagine is to be regarded as the analogue in the vegetable kingdom of carbamide in the animal kingdom. It is pointed out that the process is reversible, and in absence of carbohydrates degradation of protein to asparagine or glutamine, and finally to ammonia, occurs.

G. F. M.

**Incrustive Substances of Plants. III.** ERICH SCHMIDT, EBERHARD GEISLER, PAUL ARNDT, and FRITZ IHLOW (*Ber.*, 1923, 56, [B], 23—31; cf. A., 1921, i, 912; 1922, i, 206).—Further examination has confirmed the previous observation that aqueous solutions of chlorine dioxide are specific reagents for the removal of botanical incrustations. The cell-membranes of the higher fungi, archegoniates, and phanerogams are thus shown to be composed of tissue containing chitin or cellulose accompanied by hemicelluloses and pentosans and incrustation containing hexosans and pentosans accompanied by those portions of the cell-membrane which are attacked by chlorine dioxide.

The concentration of the chlorine dioxide solution (about 6%) is considerably greater than that recommended previously (*loc. cit.*). Its preparation from potassium chlorate, crystalline oxalic acid, and sulphuric acid is described in detail. Like the more dilute solution, it is without action on the tissue of plants.

For the removal of incrustations, the finely divided portions of plants are treated with an approximately 6% aqueous solution of chlorine dioxide in closed bottles at the atmospheric temperature in diffused daylight during seventy-two hours with occasional agitation. The precipitate is filtered and the residue mechanically agitated with water and again filtered. The combined filtrates are well stirred in a large porcelain dish to remove chlorine dioxide, and are afterwards dialysed against running water for at least forty-eight hours; they are subsequently evaporated to dryness under diminished pressure. The original residue is treated with a hot aqueous solution of crystalline sodium sulphite (2%) and the mixture filtered. The residue is thoroughly washed and the united filtrate and wash waters are dialysed against running water for at least seventy-two hours. They are subsequently evaporated to dryness under diminished pressure and the residue is united with that obtained by the treatment with chlorine dioxide. The product is separated by means of boiling absolute alcohol into

insoluble polysaccharides which usually contain 5–10% of ash (this cannot readily be removed by dialysis, but is reduced to about 1.5%, consisting chiefly of silica, by electro-osmosis) and soluble components of the membrane which are attacked by chlorine dioxide.

The method described previously (*loc. cit.*) for the preparation of skeleton substance completely free from incrustation requires to be supplemented by a second treatment with chlorine dioxide solution (0.2%) and sodium sulphite (2%). The residue is well filtered and placed first in alcohol and then in ether for about twenty-four hours. After being dried in a desiccator, it is thus obtained as a spongy material.

The quantitative estimation of tissue and incrustation is modified and carried out in small pressure bottles according to the process outlined above. Beech wood is thus shown to contain 54.09% of tissue and 45.91% of incrustation.

H. W.

**Amylase in Plants. I. The Production and Behaviour of Amylase in Living Plants.** KNUT SJÖBERG (*Biochem. Z.*, 1922, 133, 218–293).—Following Euler and Svanberg (*A.*, 1919, i, 614), the author finds that the amylolytic activity of plant preparations is conveniently measured as  $S = km/P$ , where  $k$  is the mean value of the reaction coefficient, calculated as a unimolecular reaction,  $m$  is the maximum weight of maltose produced, and  $P$  is the weight of the preparation applied, the maltose being produced from the starch by the preparation under standard conditions as regards  $p_H$  and temperature. From measurements of the maltose at various times,  $k$  is calculated. The optimum  $p_H$  for plant diastase is from 5 to 5.4. During the ripening of seeds there occurs a very marked increase of the amylase. Various plants at various seasons have been investigated, and it is found that the amylase activity varies very greatly, being greatest in young leaves. Algæ increase in amylase when nourished in a solution containing starch, calcium lactate, or calcium tartrate, whereas a decrease occurs if the solution contains sucrose, lactose, maltose, glucose, or galactose. Generally speaking, there is no correlation between the content of a plant in amylase, and in starch, or in sugar.

W. O. K.

**Amylase in Plants. II. The Sensitiveness of the Amylase of *Phaseolus vulgaris* to Temperature.** KNUT SJÖBERG (*Biochem. Z.*, 1922, 133, 294–330).—An investigation of the amylase of *Phaseolus vulgaris* shows that there are two enzymes concerned in the conversion of starch into sugar. The rate of disappearance of starch has the same temperature constant,  $A = \log(k_2/k_1)T_1T_2/0.4343(T_2 - T_1)$  between 20° and 40° of about 9600, follows the law of a unimolecular reaction, and, moreover, the enzyme causing the disappearance of the starch is destroyed by sodium chloride. On the other hand, the rate of formation of sugar has a temperature constant varying from 10,000 at 20°, to 5700 at 40°, its inactivation does not follow the law of a uni-

molecular reaction, and there is no inhibition by sodium chloride. For the formation of sugar, the optimum  $p_H$  is from 5 to 5.5, and for the disappearance of starch it is from 4 to 6. The amylase is most stable at  $p_H$  6.5–7.0. The temperature at which the enzymes are wholly destroyed is  $45^\circ$  for both enzymes. W. O. K.

[Constituents of] Cork. P. KARRER, J. PEYER, and ZORRA ZEGA (*Helv. Chim. Acta*, 1922, 5, 853–863).—The carbohydrates contained in cork were studied in the course of an attempt to characterise in a more satisfactory manner than heretofore the constituents of cork. After removing the alcohols by extraction with solvents and hydrolysing with alcoholic potash to remove fatty acids, a residue was left equal to about 8% of the weight of the original air-dried cork. When this was treated with acetic anhydride and anhydrous zinc chloride at  $50$ – $60^\circ$ , part of it went into solution, and when the solution was poured into water a precipitate resembling cellulose acetate was thrown down. It had  $[\alpha]_D^{20}$   $-21.2^\circ$  to  $-22.1^\circ$  and on hydrolysis gave dextrose. By repeating the process several times on the cork residue, less pure fractions with a smaller laevorotation were obtained. The total yield obtained was about 12.1 g. of acetyl product from 430 g. of original cork. From it a very small quantity of crystalline cellobiose octa-acetate was obtained. A similar yield of acetyl compound was obtained by treating unhydrolysed cork with acetic anhydride and zinc chloride. Since the residue retained all the properties of the original cork, it is concluded that the carbohydrates cannot play any important part in the structure of the cork. It has been suggested by Grün and Wittka (*A.*, 1922, i, 114) that cellulose esters of higher fatty acids may be constituents of cork-like substances. The properties of such substances as cellulose hexapalmitate, however, do not resemble those of cork. The following are described.

*l*-Glucosan tripalmitate,  $C_{54}H_{100}O_8$ , prepared by the action of palmityl chloride on *l*-glucosan in chloroform solution in presence of quinoline, forms fine, white needles, m. p.  $68.5^\circ$ ,  $[\alpha]_D^{20} -21.08^\circ$ . *l*-Glucosan tristearate,  $C_{60}H_{112}O_8$ , prepared in the same way as the last, m. p.  $73.4^\circ$ ,  $[\alpha]_D^{20} -18.4^\circ$ . Cellulose hexapalmitate,

$C_{12}H_{14}O_{10}(CO-C_{15}H_{31})_6$ , prepared in a similar way, is a white, amorphous substance, m. p.  $78^\circ$ ,  $[\alpha]_D^{20} -3.0^\circ$ . E. H. R.

The Starch of Floridean Algæ. G. MANGENOT (*Compt. rend.*, 1923, 176, 183–185).—In the main a discussion of the subject from the point of view of plant physiology. The starch of the Florideæ, both from the chemical and physiological point of view, behaves like typical starch, except that its colour with iodine in potassium iodide distinguishes it slightly. W. G.

Biochemical Study of the *Laminaria*. Variations in the Chief Constituents. Their Relationships, Dependence on External Conditions, and their Functions. P. FREUNDLER, (Mlle) LAURENT, and (Mlle) MÉNAGER (*Bull. Soc. chim.*, 1922, [iv], 31, 1341–1347; cf. *A.*, 1922, i, 98).—Further examination

of certain species of *Laminaria* shows that at the end of winter they are all completely deprived of carbohydrate reserve material, which in September attained a maximum of about 40%. At this period also the perennial *Laminaria* contain little or no "fixed" iodine. The energy for the early spring growth is thought to be provided by a reserve of iodine which is stored up by means of a special pigment which is not found in the annual algæ, and is transported to the growing areas by means of the algin. A lack of sunshine, as in 1922, is accompanied by a considerable diminution of iodine in certain regions, but it is not so pronounced in places under the influence of warm ocean currents. The greater part of the iodine in the algæ is present in unstable organic combination, but it was found that the amount that could be estimated by incineration increased spontaneously on keeping. Closely associated with the iodine are a yellow pigment decolorisable by sodium hydrogen sulphite, and a red pigment found only in deep-water algæ, which is insoluble in the sulphite, but soluble in ammonia with an intense red colour. The algin appears to act as salt concentrators. They absorb, for example, 20–25% of their weight of calcium or alkali metal chlorides, giving insoluble gels (alkali alginates). The presence of hydrolysing and alcohol-forming enzymes was established.

G. F. M.

**Phycocerythrin in the Myxophyceæ.** N. WILLE (*Ber. Deut. bot. Ges.*, 1922, 40, 188–192).—The occurrence is recorded of a phycocerythrin in a species of Myxophyceæ, identified as *Phormidium persicinum* growing 3–4 fathoms deep off the south coasts of Norway, which gives an absorption spectrum identical with that of the phycocerythrin found in the Floridææ, and is undoubtedly identical in other respects with that substance. A phycocerythrin has already been detected by Boresch in other species of Myxophyceæ, but this was apparently different from the colouring matter of the Floridææ, as it showed only one absorption band in the green, whilst the colouring matter of *P. persicinum* shows three bands, that near the F line being particularly characteristic of the phycocerythrin of the Floridææ.

G. F. M.

**The Pigment of the Alga *Palmellococcus miniatius*, Chod., var. *porphyrea*, Wille.** K. BORESCH (*Ber. Deut. bot. Ges.*, 1922, 40, 288–291).—The water-soluble pigment which occurs in a species of *Palmellococcus* found growing in moist places in the Botanical Garden in Prague and identified by Wille as *P. miniatius*, Chod., var. *porphyrea*, was identified by its absorption spectrum and reactions as a mixture of phycocyanin, and the phycocerythrin characteristic of the Schizophyceæ. The identity of the pigments in such widely-separated groups of algæ points to the common chemico-physiological relationship of plants.

G. F. M.

**The Occurrence of *d*-Quercitin in the Seed Kernels of *Achras sapota*, L.** A. W. VAN DER HAAR (*Rec. trav. chim.*, 1922, 41, 784–786).—*d*-Quercitin together with the saponins was

extracted from the dried and powdered seeds by means of methyl alcohol and separated from the saponins by precipitation with ether followed by extraction of the precipitate with methyl alcohol. The product was shown by various tests to be identical with the *d*-quercitin obtained from acorns. The author states that the mixture of lactose and sucrose obtained by Bouchardat (A., 1871, 1915) from the sap and also from the ripe fruit of *Achras sapota* was in reality a mixture of sucrose with quercitin. H. J. E.

**The Localisation of the Hydrocyanic Acid Glucosides and of Emulsin in Bitter Almonds and in Cherry-laurel Leaves.** L. ROSENTHALER and K. SEILER (*Ber. Deut. pharm. Ges.*, 1922, 32, 245—248).—A method is described for the microscopic detection of hydrocyanic acid from the glucoside and emulsin in the plant-tissues (cf. *Schweiz. Apoth. Ztg.*, 1922, 60, 477). In bitter almonds, both amygdalin and emulsin are found in all tissues except the shell. Detailed data are given of the distribution of prulaurasin and emulsin in the leaves of the cherry-laurel at the beginning of March. In general, both substances occur in the same tissues, although there are some in which prulaurasin is found without emulsin. Where the emulsin and the hydrocyanic acid glucoside are present in the same cell and yet do not react, there must be some internal separation of them within the cell.

P. M.

**The Odorous Constituents of Apples. II. Evidence of the Presence of Geraniol.** FREDERICK B. POWER and VICTOR K. CHESNUT (*J. Amer. Chem. Soc.*, 1922, 44, 2938—2942).—An examination of the essential oil from the parings of McIntosh apples, a particularly fragrant variety of the fruit, confirms the results of a previous investigation (A., 1920, i, 653), that the odorous constituents of apples consist chiefly of amyl esters, but in addition proof of the presence of geraniol was obtained. It is probable that geraniol either in the free state or in the form of esters is contained in varying amounts in all apples, but is more abundant in those varieties which possess its distinctive odour.

W. G.

**The Constituents of the Benzene Extract of American Cotton.** ROBERT GEORGE FARGHER and MAURICE ERNEST PROBERT (*J. Text. Inst.*, 1923, 14, T., 49—65).—The material at the disposal of the authors was obtained by heating approximately two tons of American cotton with commercial "90% benzol" in a rotating kier by means of steam at 40 lb. pressure, and consisted, therefore, of the material extracted with benzene, together with that removed by the condensed steam. The crude product was dried at 100° in a vacuum, when it was left as a dark brown solid wax. On the laboratory scale, the benzene extract amounted to 0.51% of the dried cotton.

The crude wax was mixed with purified sawdust and extracted by light petroleum, ether, benzene, alcohol, and chloroform, and

the extracts were submitted to exhaustive examination, which is described in detail. The following substances were isolated.

*Alcohols*.—Gossypyl alcohol is the chief constituent; montanyl alcohol occurs in smaller amount, and carnaübyl alcohol, ceryl alcohol, sitosterol, and  $\alpha$ - and  $\beta$ -amyryns are also present. Sitossterolin, the glucoside, was also encountered. *Acids*.—Palmitic, stearic, and oleic acids occur in the free state; montanic, cerotic, palmitic, and stearic acids, and a new acid, occur as salts, chiefly of sodium; whilst carnaübic, palmitic, stearic, and oleic acids, and a lower homologue of oleic acid are present as esters. *Hydrocarbons*.—Triacontane and hentriacontane have been isolated, but the bulk of the hydrocarbons present are liquid.

*Gossypyl alcohol*,  $C_{30}H_{62}O$ , is the chief constituent of the benzene extract. It occurs in three forms, differing in solubility, but yielding the same derivatives. The  $\alpha$ -form, which is the least soluble, crystallises in feathery needles, m. p. 87—88°; the  $\beta$ -form separates in leaflets, m. p. 85—87°; and the  $\gamma$ -modification forms small leaflets, m. p. 82—83°. On recovery from the acetate, the  $\alpha$ -form appears to have changed into the  $\beta$ -modification. *Gossypyl acetate* forms small, silky needles, m. p. 68—69°; the *benzoate* is a felted mass of minute needles, m. p. 65°; the *p-bromobenzoate* forms clusters of needles, m. p. 66—67°; and the *p-nitrobenzoate* crystallises in tufts of needles, m. p. 72°. The various forms of the alcohol all gave the same acid on fusion with potash-lime. *Gossypic acid*,  $C_{30}H_{60}O_2$ , crystallises in radiating clusters of needles, m. p. 85—86°; the *methyl ester* has m. p. 68—69°, the *ethyl ester*, m. p. 66—66·5°, the *amide*, m. p. 108—109°, and the *anilide*, m. p. 99·5°.

*Montanyl alcohol*,  $C_{28}H_{58}O$ , crystallises as a mass of minute needles, m. p. 85—86°; its *acetate* forms clusters of leaflets or needles, m. p. 69°; the *benzoate* has m. p. 66—67°; the *p-bromobenzoate* is a mass of minute needles, m. p. 66—66·5°; and the *p-nitrobenzoate* has m. p. 70—70·5°. On fusion with potash-lime, the alcohol yielded montanic acid which was completely identified with a sample from montan wax.

Both gossypyl and montanyl alcohols obstinately retain water, even when heated for some hours at 115° in a vacuum. The anhydrous forms were obtained by saponification of the acetates. This tendency necessitated a careful examination of their derivatives, and conversion into the substituted benzoates and the corresponding acids proved to be the best means of characterising the alcohols. Furthermore, molecular-weight determinations were successfully made by saponifying the esters and titrating.

Of the acids present, carnaübic acid and the new acid are worthy of mention. The former has been definitely characterised. It crystallises in leaflets, m. p. 72—73°; the *methyl ester* has m. p. 55—56°, the *ethyl ester*, m. p. 52—53°; the *amide*,  $C_{23}H_{47}\cdot CO\cdot NH_2$ , m. p. 103·5°; and the *anilide*, m. p. 94—94·5°. The new acid,  $C_{34}H_{68}O_2$ , is possibly identical with an acid found by Schalfée in 1876, associated with the melissic acid of beeswax; it separates in fern-like clusters, m. p. 90—91°; the *methyl ester* has m. p. 75—76°, the *amide*, m. p. 108—109°, and the *anilide*, m. p. 105°.

The liquid hydrocarbons were divided into five fractions boiling between 170° and 220°, under 28 mm., and five more with b. p. 150—210°/1 mm. All the oils were pale yellow and reacted with a solution of bromine in chloroform. Densities and refractive indices are recorded. J. C. W.

***Stenocalix pitanga*, Berg, or *Eugenia pitanga*, Berg-Arech (Pitanga or Nangapire).** VÍCTOR COPPERTI and MATÍAS GONZÁLEZ (*Anal. Fis. Quím.*, 1922, 20, 406—419).—The leaves of *Eugenia pitanga*, a Uruguayan tree, yield an essential oil, which contains as its principal constituents citronellol, geranyl acetate, geraniol, cineol, terpinene, sesquiterpenes, and polyterpenes. A resin also occurs composed of resin acids, resens, and resinotannols. Alkaloids, glucosides, bitter principles, and other neutral substances are absent. The leaves are not toxic. G. W. R.

**Examination of Authentic Grape Juices for Methyl Anthranilate.** FREDERICK B. POWER and VICTOR K. CHESNUT (*J. Agric. Res.*, 1923, 23, 47—53).—Grapes usually regarded as representing pure-bred *Vitis labrusca*, which includes the concord, the commonest variety grown in the Eastern States of America and used for edible purposes and the preparation of unfermented grape juice, all contain methyl anthranilate. With few exceptions it was also found in varying amounts in hybrids of *V. labrusca*, especially when this species predominates. On the other hand, this ester could not be detected in juices from Californian grapes which are derived from *V. vinifera*, the European cultivated species, nor from *V. rotundifolia*, the species grown in the Southern States. It is suggested that the presence or absence of methyl anthranilate may possess some diagnostic value in determining the botanical relationship of varieties of uncertain origin. In those varieties in which it occurs methyl anthranilate doubtless imparts a distinctive odour, but it does not completely account for the entire aroma, and a complete chemical examination of the odorous constituents still remains to be accomplished. G. F. M.

**The Presence of Aucubin and Melampyritol [Dulcitol] in some Species of Melampyrum.** (Mlle) MARIE BRAECKE (*Compt. rend.*, 1922, 175, 990—992; cf. Bridel and Braecke, A., 1922, 1, 209, 799).—Following the extraction of aucubin from *Melampyrum arvense*, an attempt was made to ascertain whether it is present in other species, and also whether dulcitol, present in *M. nemorosum* and *M. arvense*, could be found. Aucubin was obtained in pure condition from *M. cristatum*, *M. nemorosum*, and *M. pratense*; dulcitol is present in *M. cristatum*, but was not obtained from *M. pratense*. H. J. E.

**Confirmation of the Occurrence of Linalyl Esters in Peaches.** FREDERICK B. POWER and VICTOR K. CHESNUT (*J. Amer. Chem. Soc.*, 1922, 44, 2966—2967; cf. A., 1922, 1, 99).—In addition to the formation of citral by the oxidation of the alcohol

mixture arising from the saponification of the esters obtained from peaches the authors have now proved the presence of acetone and lævulinic acid in the products of oxidation. These substances were also obtained by the oxidation of linalool itself, and thus confirmation of the presence of linalyl esters in peaches was obtained.

W. G.

**The Enzymes of the Latex of the Indian Poppy (*Papaver somniferum*).** HAROLD EDWARD ANNETT (*Biochem. J.*, 1922, 16, 763—769).—The latex of the Indian opium poppy has a powerful oxidising action on guaiacum tincture, pyrogallol, benzidine, and tyrosine in the absence of hydrogen peroxide. The reaction is inhibited by the presence of this reagent. The actions on benzidine and tyrosine are particularly powerful. The dialysed latex before and after filtration also oxidises the above reagents. Opium powder stored for three years contains an oxidising enzyme which acts on benzidine. It is suggested that the loss of morphine in dry opium powder on storage may be due to the action of oxidising enzymes. Amylase, invertase, maltase, emulsin, and urease are absent from the latex, which shows, however, a weak proteolytic activity.

S. S. Z.

**The Bark of *Tiliacora acuminata*, Miers.** L. VAN ITALLIE and A. J. STEENHAUER (*Pharm. Weekblad*, 1922, 59, 1381—1388).—Among the products obtained from the alcoholic extract of the dry powdered bark is a new alkaloid, *Tiliacorine*, of m. p. 260—261°, decomp.,  $\alpha_D +105.3^\circ$ , and composition  $C_{30}H_{27}O_3N(OMe)_2$ . The methoxy-groups were estimated by Zeisel's method, but no other light could be obtained on the constitution. (See *J.S.C.I.*, 1923, 159A.)

S. I. L.

**The Presence of Aucubin in the Seeds of *Veronica hederæ-folia*, L.** C. CHARAUX (*Bull. Soc. Chim. biol.*, 1922, 4, 568—570).—A glucoside, isolated from the seeds of *Veronica hederæ-folia* by extraction with alcohol in presence of calcium carbonate, has been identified as aucubin, m. p. 180°,  $[\alpha]_D -163.5^\circ$ . W. O. K.

**The Chemical Composition of Soja Bean Oil.** WALTER F. BAUGHMAN and GEORGE S. JAMIESON (*J. Amer. Chem. Soc.*, 1922, 44, 2947—2952).—The sample of soja bean oil examined had  $d_4^{20}$  0.9203;  $n_D^{20}$  1.4736; iodine number (Hanus) 128.0; saponification number, 189.5; acid number, 0.5; acetyl number, 17.0; Reichert-Meißl number, 0.16; Polenske number, 0.26; unsaponifiable matter, 0.6%; saturated acids, 11.5%; unsaturated acids, 83.5%. Detailed analysis showed its composition to be as follows: Glycerides of linolenic acid 2.3%, of linolic acid 51.5%, of oleic acid 33.4%, of palmitic acid 6.8%, of stearic acid 4.4%, of arachidic acid 0.7%, and of lignoceric acid 0.1%, and 0.6% of unsaponifiable matter. Total 99.8%.

W. G.

**The Chemical Composition of Sunflower-seed Oil.** GEORGE S. JAMIESON and WALTER F. BAUGHMAN (*J. Amer. Chem. Soc.*, 1922, 44, 2952—2957).—The sample of sunflower-seed oil from

south-eastern Missouri examined had  $d_{20}^{25}$  0.9193;  $n_D^{20}$  1.4736; iodine number (Hanus), 130.8; saponification number, 188.0; acid number, 2.3; acetyl number, 14.5; Reichert-Meissl number, 0.27; Polenske number, 0.25; unsaponifiable matter, 1.20%; saturated acids, 7.1%; unsaturated acids, 86.6%. Detailed analysis showed its composition to be as follows: Glycerides of oleic acid 33.4%, of linolic acid 57.5%, of palmitic acid 3.5%, of stearic acid 2.9%, of arachidic acid 0.6%, and of lignoceric acid 0.4%, and 1.2% of unsaponifiable matter. Total 99.5%.

W. G.

**The Genesis of Carbohydrates in Wheat. Presence of Lævulosans in the Stem.** H. COLIN and H. BELVAL (*Compt. rend.*, 1922, 175, 1441—1443).—Prior to the formation of the ear, the stem of the wheat plant contains only those carbohydrates coming to it from the leaf, and the ratio of reducing sugars to sucrose is much greater in it than in the leaf. From the month of June, however, as soon as the corn has shot, a change occurs. After the sugars have been extracted by alcohol from the stem a residue remains which, on hydrolysis with acid, gives a large amount of lævulose and at the time of ripening the carbohydrates of the stem consist of sucrose and lævulosans.

W. G.

**Bird-lime. III.** YUSHICHI NISHIZAWA (*J. Chem. Soc. Japan*, 1922, 43, 810—817; cf. A., 1921, i, 760; 1922, i, 652).—The decomposition products of white bird-lime have been studied. A mixture of powdered calcium oxide and bird-lime was subjected to dry distillation at the ordinary pressure and the product was fractionated at about 48 mm. pressure, the refractive indices of the fractions being measured. The fraction distilling at 155—160°/48 mm. had the formula  $C_{14}H_{28}O$  or  $C_{15}H_{30}O$ ; it did not give an aldehydic reaction. The fraction distilling at about 155°/48 mm. absorbed 8.3 g. of ozone; the product on decomposition with boiling water gave an oily aldehydic compound, its oxime had m. p. 76°, and the semicarbazone, colourless plates, m. p. 91°. From the fraction distilling at 200—270°/5—7 mm. crystals, m. p. 82°, were obtained which gave an oxime, m. p. 58°, and semicarbazone, m. p. 170°, and proved to be identical with palmitone obtained by the distillation of calcium palmitate.

K. K.

**The Soil Solution Extracted by Lipman's Direct Pressure Method compared with 1:5 Water Extracts.** PAUL S. BURGESS (*Soil Sci.*, 1922, 14, 191—216).—Analysis of 1:5 water extracts and of the soil solution shows that if all the soil moisture be assumed to act as solvent, the soil solution contains approximately as much calcium, magnesium, and nitrate as is removed in the extract, but considerably less phosphate, potash, and sulphate. On the assumption that "unfree water" exists, the amount of calcium, magnesium, nitrate, and sulphate in the extract is about twice that in the soil solution; and phosphate and potassium are in considerably larger proportions.

A. G. P.

**The Relation of Soil Moisture to Physiological Salt Balance for Plants.** JOHN W. SHIVE (*Soil Sci.*, 1922, 14, 391—411).—Crop yields on soils at various moisture-contents and with the addition of various fertilising salt mixtures were examined. It was shown that the salt balance characteristic of high yields is not markedly affected by the moisture content, provided the osmotic pressure of added solutions is roughly the same. Only when the total concentration of the solutions added to the soil were widely different was there any serious alteration in the optimum salt balance. The effect of moisture conditions on crop yield is as great as that brought about by varied fertiliser treatment. Unfavourable moisture conditions cannot be corrected by any kind of fertiliser treatment. Fertilisers cannot be utilised efficiently by the plant unless the optimum soil moisture obtains. A. G. P.

**The Potential Acidity of Soils.** OLOF ARRHENIUS (*Soil Sci.*, 1922, 14, 223—232).—The potential acidity or buffer action of soils was shown in many cases to be correlated with the type of titration curve and with soil fertility, a high buffer capacity being usually associated with a productive soil. The lime requirement of soils may be determined from data showing the relative changes in  $pH$  values brought about by titration with alkali and acid. A. G. P.

**The Measurement of Soil Acidity by Means of Alkaline Solutions.** V. VINCENT (*Compt. rend.*, 1922, 175, 1233—1234).—Solutions of lime-water and of calcium or sodium hydrogen carbonate give inconsistent results when used for measuring soil acidity, the latter giving a lower value as the organic matter in the soil combines more completely with the lime-water, whereas the hydrogen carbonate only measures organic acids together with the acidity due to aluminium salts. It is stated that these facts afford some explanation of the physical reaction of soils to the addition of calcium compounds and that the nature of the calcium compound conditions the alkalinity of the soil water. H. J. E.

**Absorption by Colloidal and Non-colloidal Soil Constituents.** M. S. ANDERSON, W. H. FRY, P. L. GILE, H. E. MIDDLETON, and W. O. ROBINSON (*U.S. Dept. Agr. Bull.*, 1922, 1122, 1—20).—A complete separation of the colloidal matter from the finer mineral particles of the soil was not found possible and a direct determination could therefore not be made of the relative absorption in soils due to colloids and non-colloids from a fractionation of the soil into these two classes of materials. From a study of the absorptive capacities of twenty-one soil minerals powdered to definite sizes varying between 1 and 50 microns in diameter, it was calculated that except in the case of the most highly micaceous soils in which the non-colloidal absorptions might reach 10—20% of the whole soil absorption, less than 5% of the total absorption of the soil is due to the non-colloidal part. Absorption by non-colloidal constituents should therefore

not seriously affect absorptive methods for estimating the amount of colloids in soil. Minerals ground to a state of subdivision probably equal to that of the mixed soil colloids, or "ultra clays," absorb less than the average ultra clay. The average absorption of peat and synthetic inorganic gels, on the other hand, is more nearly like that of the ultra clays. The fact that soil colloids are not merely finely comminuted minerals but appear to be of quite different nature from the non-colloidal particles thus affords an explanation for the marked difference in the absorptive capacities of these two classes of soil materials. CHEMICAL ABSTRACTS.

**Influence of the Calcium-Magnesium Ratio on Soils under Continuous Cultivation.** H. H. HILL (*Virginia Agr. Exp. Sta., Tech. Bull.*, 1922, 24, 1—15).—Continuous cropping of a loam soil with maize was found to change the ratio of calcium to magnesium in the soil from about 1:1 to 1:2. Good results were obtained with equal proportions of magnesium and calcium, but when magnesium was in excess, crop exhaustion was manifest. When acid phosphate was used alone, the calcium:magnesium ratio was not as wide as on the plots which received mixtures of acid phosphate, potassium sulphate, and sodium nitrate; potassium sulphate and sodium nitrate when applied alone exerted no appreciable effect on the retention of calcium. CHEMICAL ABSTRACTS.

**(Theoretical and Practical Principles of) Carbon Dioxide Manuring.** HENRIC LUNDEGÅRDH (*Angew. Botanik*, 1922, 4, 120—151; from *Chem. Zentr.*, 1922, iii, 1387).—The intensity of carbon dioxide assimilation by the leaves of beans and potatoes in closed cylinders in full daylight is nearly proportional to the concentration of carbon dioxide in the air up to two to four times the normal amount. Assimilation is increased even when the carbon dioxide content is further increased. From analyses of the atmosphere in the vicinity of leaves of growing crops it is shown that the proportion of carbon dioxide present and available for assimilation varies with different types of manuring by about 28%. The carbon dioxide concentration is increased by artificial fertilisers as well as by farmyard manure. It is shown that the carbon dioxide concentration at the level of assimilating leaves is controlled by the production of carbon dioxide in the soil. In the layers immediately above the soil, it is only slightly affected by wind velocity. Rain and warmth increase the production of carbon dioxide by the soil and, consequently, its assimilation by plants. G. W. R.

---

## Organic Chemistry.

**The Oxidation of Hydrocarbons, with Special Reference to the Production of Formaldehyde. II. The Action of Oxygen on Methane.** T. SHERLOCK WHEELER and E. W. BLAIR (*J. Soc. Chem. Ind.*, 1923, 42, 81—86, 87—92r).—In continuation of previous work on the oxidation of ethylene (A., 1922, i, 1105), the authors have investigated the oxidation of methane, more especially as regards the effects of temperature, time of heating, catalysts, etc., on the production of formaldehyde. The results obtained indicate that a short time of heating and slow oxidation are the principal factors determining a good yield of formaldehyde. The higher the temperature the more liable formaldehyde, in a given concentration, is to decompose or oxidise. At 500°, it does not decompose rapidly if present in concentrations below 2%. At concentrations below 0.2%, formaldehyde is completely unstable at 720°. With shorter times of heating, equimolecular mixtures of methane and oxygen give the higher yields of formaldehyde; for longer times and probably also for higher temperatures, the yields are greater in the case of mixtures containing excess of hydrocarbon. In all cases, the yield of formic acid is very small. Whereas the presence of a very small amount of ammonia increases the stability of this product, no similar effect is observed with formaldehyde. The results are in agreement with the hydroxylation theory of the oxidation of methane proposed by Bone.

J. S. G. T.

**The Oxidation of Paraffin by means of Atmospheric Oxygen.** ADOLF GRÜN and E. ULBRICH (*Z. angew. Chem.*, 1923, 36, 125—126).—The yield of total and insoluble fatty acids in the oxidation of paraffin with air is very largely increased by increasing the rapidity of the air current. By increasing the current of air from 150 litres to 1200 litres per hour, other conditions being kept constant, the yield of insoluble fatty acids was increased from 36.5% to 61.7%. The yield is also dependent on the moisture content of the air, but the data obtained on this point are somewhat conflicting. The increase of yield caused by the more rapid air current is chiefly due to the more efficient stirring which occurs, but also partly to the increased volume of oxygen made available. Experiments carried out with air diluted with various proportions of carbon dioxide showed that gas mixtures containing as little as 1.3% by weight of oxygen exert a marked oxidising effect when passed through paraffin heated at 160°.

H. C. R.

**The Reaction between Ethylenic Hydrocarbons and the Grignard Reagent.** HENRY GILMAN and H. MARJORIE CRAWFORD (*J. Amer. Chem. Soc.*, 1923, 45, 554—558).—A quantitative study of the behaviour of magnesium methyl iodide towards a number of hydrocarbons having one or more ethylenic linkings in their

molecule shows that there is not an addition of the Grignard reagent to such a linking. This applies not only to the ordinary conditions but also in a case where an excess of the organo-magnesium halide was used or the ordinary ether was replaced by *n*-butyl ether as a solvent. W. G.

**Preparation and Reactions of Bromopicin.** LOUIS HUNTER (T., 1923, 123, 543—549).

**Unsaturated Residues in their Chemical and Pharmacological Relationship.** IV. JULIUS VON BRAUN and WERNER SCHIRMACHER (*Ber.*, 1923, 56, [B], 538—548).—It has been shown previously that unsaturated hydrocarbon residues are not firmly united with halogen, oxygen, sulphur, or nitrogen if the double bond is in the  $\beta\gamma$ -position with respect to these atoms. The effect of the lengthening of the hydrocarbon chain has been examined by a comparison of the stability of  $\Delta^2$ -butenyl compounds with the corresponding allyl derivatives. Somewhat unexpectedly, the butenyl compounds are found to be less stable than the allyl compounds. Pharmacologically the butenyl resemble the allyl derivatives in their action, but are somewhat less powerful.

$\Delta^2$ -Butenyl bromide is considerably more readily hydrolysed by water at 18° than is allyl bromide. The transformation of  $\Delta^2$ -butenyl bromide into *trimethyl- $\Delta^2$ -butenylammonium bromide*, a colourless, hygroscopic, crystalline mass, m. p. 165°, by trimethylamine dissolved in benzene takes place about two hundred times as rapidly as the conversion of *n*-butyl bromide into *trimethyl-n-butylammonium bromide*, m. p. 182°, under similar conditions.  $\Delta^2$ -Butenyl bromide reacts very readily with magnesium, giving an octadiene, b. p. 113—114°,  $d_4^{20}$  0.7420,  $n_D^{20}$  1.4324.  $\Delta^2$ -Butenyl bromide and magnesium phenyl bromide gives  *$\Delta^2$ -butenylbenzene*,  $C_6H_5\cdot CH_2\cdot CH:CHMe$ , a colourless liquid, b. p. 61—63°/12 mm.,  $d_4^{20}$  0.9069,  $n_D^{20}$  1.5157, the yield being 61% of that theoretically possible. Magnesium *p*-anisyl bromide and  $\Delta^2$ -butenyl bromide yield *p- $\Delta^2$ -butenylanisole*, b. p. 108—109°/12 mm.,  $d_4^{20}$  0.9715,  $n_D^{20}$  1.5229; the double bond in this substance appears to be very resistant to displacement towards the benzene nucleus. It is readily hydrogenated in methyl-alcoholic solution in the presence of palladium to *p-n*-butylanisole, a colourless liquid, b. p. 104—105°/10 mm.,  $d_4^{20}$  0.9396,  $n_D^{20}$  1.5045.

*Phenyl  $\Delta^2$ -butenyl ether*, a liquid, b. p. 95—98°/12 mm.,  $d_4^{20}$  0.969,  $n_D^{20}$  1.5187, is obtained in almost theoretical yield by the method recommended by Claisen and Eisleb (A., 1913, i, 1175) for the corresponding allyl compound. It is relatively more readily isomerised than the allyl derivative when heated, yielding *o- $\Delta^2$ -butenylphenol*, b. p. 108—112°/10.5 mm.,  $d_4^{20}$  1.0066,  $n_D^{20}$  1.5385; the latter substance gives non-crystalline benzoyl and *p*-nitrobenzoyl compounds, and is converted by methyl sulphate into *o- $\Delta^2$ -butenylanisole*, b. p. 102—105°/12 mm.,  $d_4^{20}$  0.9721,  $n_D^{20}$  1.5255. Similarly,  $\alpha$ -naphthyl  $\Delta^2$ -butenyl ether is partly isomerised when distilled in a vacuum to 2- $\Delta^2$ -butenyl- $\alpha$ -naphthol,

a yellow liquid, b. p. 177—180°/12 mm. (the corresponding *methyl ether* is a colourless liquid, b. p. 164—166°/13 mm.).

$\Delta^8$ -Butenyl bromide reacts very readily with ammonium thiocyanate dissolved in alcohol, but the primarily-formed  $\Delta^8$ -*butenyl thiocyanate* becomes isomerised when distilled to the corresponding thiocarbimide, b. p. 158—159° (*phenyl- $\Delta^8$ -butenylthiocarbimide* crystallises in colourless needles, m. p. 110°).

*Methyl- $\Delta^8$ -butenylaniline* is a colourless liquid, b. p. 118—120°/14 mm., which yields a non-crystalline *hydrochloride* and *picrate* and a *methiodide*, m. p. 109°. It is readily converted by cyanogen bromide into the non-crystalline, *phenylmethylidibutenylammonium bromide* (the corresponding *chloroplatinate* is a pale yellow powder, decomp. 145°), and *phenylmethylecyanamide*, b. p. 139—140°/14 mm., m. p. 32°. *Allyl- $\Delta^8$ -butenylaniline*, prepared from  $\Delta^8$ -butenyl bromide and allylaniline, is a colourless liquid, b. p. 127—130°/12 mm., which gives a non-crystalline *hydrochloride* and *methiodide* and a *picrate*, m. p. 120°. It is converted by cautious treatment with cyanogen bromide into the non-crystalline *phenylallyldibutenylammonium bromide* (corresponding *chloroplatinate*, decomp. 109°) and *phenylallylcyanamide*, a colourless liquid, b. p. 153—155°/12 mm., which is also obtained from allylaniline and cyanogen bromide.

$\Delta^8$ -*Butenylhomocholine*,  $\text{CHMe}\cdot\text{CH}\cdot\text{CH}_2\cdot\text{NMe}_2\cdot\text{Br}\cdot[\text{CH}_2]_3\cdot\text{OH}$ , a colourless, very hygroscopic, crystalline mass, m. p. 52°, is readily prepared from  $\gamma$ -hydroxypropyldimethylamine and  $\Delta^8$ -butenyl bromide in benzene solution.

$\Delta^8$ -*Butenylnorcodeine* has m. p. 44° after softening at 40°. The corresponding *picrate*, m. p. 128°, and *chloroplatinate*, decomp. 198—200°, are described; the *hydrochloride* has little tendency towards crystallisation.

*Ethyl di- $\Delta^8$ -butenylmalonate*, b. p. 152—154°/17 mm., is prepared in 80% yield from butenyl bromide and ethyl malonate; the corresponding acid could not be caused to crystallise. The ester is converted by sodium ethoxide and carbamide into di-

$\Delta^8$ -*butenylbarbituric acid*,  $\text{CO}\begin{smallmatrix} \text{NH}\cdot\text{CO} \\ \text{NH}\cdot\text{CO} \end{smallmatrix}\text{C}(\text{CH}_2\cdot\text{CH}\cdot\text{CHMe})_2$ , leaflets, m. p. 109° (the *sodium salt* and the additive *product* with bromine, m. p. 195°, are described). H. W.

**The Function of Phosphoric Oxide in the Elimination of Water from Ethyl Alcohol and Ether.** D. BALAREFF (*J. pr. Chem.*, 1922, [ii], 368—377).—The dehydrating action of phosphoric oxide on ethyl alcohol vapour, the water in which exerts an appreciable partial pressure, or ethyl ether vapour (cf. Nef, A., 1901, i, 626) is partly catalytic and partly dependent on the formation of unstable additive products. At the ordinary temperature, ethyl alcohol gives, with phosphoric oxide, metaphosphoric acid, and the esters,  $\text{Et}_2\text{H}_2\text{P}_2\text{O}_7$ ,  $\text{EtH}_2\text{PO}_4$ ,  $\text{Et}_2\text{HPO}_4$ , and  $\text{Et}_3\text{PO}_4$ , and perhaps other compounds; with metaphosphoric acid,  $\text{EtH}_2\text{PO}_4$ . Phosphoric oxide dehydrates the esters  $\text{EtH}_2\text{PO}_4$  and  $\text{Et}_2\text{HPO}_4$ , giving a mixture of ethyl metaphosphate and pyrophosphate. W. S. N.

**Aliphatic Nitro-alcohols. The Degradation of Nitrotrimethyleneglycol.** RUDOLF WILKENDORF and MAX TRENNEL (*Ber.*, 1923, 56, [B], 611—620).—It has been shown by Henry in 1895 that "nitroisobutyglycerol,"  $\text{NO}_2\cdot\text{C}(\text{CH}_2\cdot\text{OH})_3$ , is readily obtained by the condensation of nitromethane with formaldehyde under the influence of alkali hydroxides. The removal of one molecule of formaldehyde from the compound with the formation of sodionitrotrimethylene glycol,  $\text{NO}_2\cdot\text{CNa}(\text{CH}_2\cdot\text{OH})_2$ , has been effected by Schmidt and Wilkendorf (*A.*, 1919, i, 249) by means of sodium ethoxide, but the further removal of a second molecule of formaldehyde with production of  $\beta$ -nitroethyl alcohol could not be effected. If, however, the metallic atom in sodionitrotrimethylene glycol is replaced by halogen and the product is treated with sodium ethoxide,  $\beta$ -chloro- $\beta$ -nitroethyl alcohol is produced in accordance with the equation  $\text{NO}_2\cdot\text{CCl}(\text{CH}_2\cdot\text{OH})_2 + 2\text{NaOEt} = \text{NO}_2\cdot\text{CNaCl}\cdot\text{CH}_2\cdot\text{ONa} + 2\text{EtOH} + \text{H}\cdot\text{CHO}$ . If now the chloronitroethyl alcohol is liberated by addition of acid, it immediately recondenses with the aldehyde to produce the original material. It is therefore necessary to remove the formaldehyde, which is conveniently effected by treating the sodio-compound with aqueous sodium hydroxide solution and nitromethane, whereby sodionitrotrimethylene glycol is produced. The mixture is acidified and the chloronitroethyl alcohol is separated from nitrotrimethylene glycol by distillation with steam. Catalytic reduction of the former compound in the presence of palladium and pyridine yields  $\beta$ -nitroethyl alcohol.

$\beta$ -Chloro- $\beta$ -nitropropane- $\alpha\gamma$ -diol is converted by a solution of sodium in ethyl alcohol into the compound,

which is transformed into  $\beta$ -chloro- $\beta$ -nitroethyl alcohol,

b. p. 103°/15 mm. The latter substance is also obtained by the condensation of chloronitromethane with formaldehyde in the presence of saturated aqueous potassium carbonate solution. The corresponding *acetate* is a colourless, viscous liquid, b. p. 101—102°/18 mm.  $\beta\beta$ -Dichloro- $\beta$ -nitroethyl alcohol, a colourless, viscous liquid, b. p. 88—89°/12 mm. (*acetate*, b. p. 105°/28 mm.), is prepared by treating an ethereal suspension of the sodium compound prepared from  $\beta$ -chloro- $\beta$ -nitropropane- $\alpha\gamma$ -diol (see above) with a slow current of dry chlorine in the absence of light.

$\beta$ -Bromo- $\beta$ -nitropropane- $\alpha\gamma$ -diol is converted by successive treatment with an alcoholic solution of sodium ethoxide and bromonitromethane (the latter combines with the liberated formaldehyde) into the compound,  $\text{NO}_2\cdot\text{CNaBr}\cdot\text{CH}_2\cdot\text{ONa}$ , which is transformed by oxalic acid in the presence of ether into  $\beta$ -bromo- $\beta$ -nitroethyl alcohol, b. p. 113°/15 mm.; the corresponding *acetate* has b. p. 110—111°/20 mm.  $\beta\beta$ -Dibromo- $\beta$ -nitroethyl alcohol has b. p. 121°/19 mm., and yields an *acetate*, b. p. 105—106°/8 mm. Catalytic reduction of  $\beta$ -chloro-,  $\beta\beta$ -dichloro-, or  $\beta$ -bromo-nitroethyl alcohol yields  $\beta$ -nitroethyl alcohol, b. p. 102°/10 mm. Treatment of an aqueous solution of  $\beta$ -nitroethyl alcohol with hydrogen in

the presence of oxalic acid and palladised barium sulphate leads to the production of  $\beta$ -hydroxylaminoethyl alcohol oxalate, m. p. 121–123° (decomp.) after softening at 119°; the corresponding free hydroxylamino-compound could not be caused to crystallise (cf. Kühn, *Diss.*, Berlin, 1922; Lutze, *Diss.*, Berlin, 1922).

$\beta\beta$ -Dichloro- $\beta$ -nitroethyl alcohol is transformed by methylalcoholic sodium methoxide solution into sodium chloride, sodium nitrite, carbon monoxide, and nitrogen. H. W.

**Preparation of some Esters and Glycidic Derivatives of Alkylglycerols.** RAMOND DELABY (*Compt. rend.*, 1923, 176, 589–591).— $\alpha\beta$ -Dibromohydrins of alkylglycerols were obtained by the action of bromine on the corresponding alkylvinylcarbinols dissolved in twice their volume of ether.  $\alpha\beta$ -Dibromobutan- $\gamma$ -ol boils at 102–105°/13 mm.,  $d_4^{20}$  1.944,  $n_D^{23}$  1.5405.  $\alpha\beta$ -Dibromopentan- $\gamma$ -ol boils at 112–115°/15 mm., and has  $d_4^{19}$  1.828,  $n_D^{20}$  1.5327.  $\alpha\beta$ -Dibromohexan- $\gamma$ -ol boils at 126–129°/13 mm., and has  $d_4^{19}$  1.724, and  $n_D^{20}$  1.5230.  $\alpha\beta$ -Dibromoheptan- $\gamma$ -ol boils at 132–133°/12 mm., and has  $d_4^{17}$  1.613 and  $n_D^{18}$  1.5191. The displacement of the hydroxyl group by a third bromine atom could only be effected by the action of phosphorus pentabromide. The resulting tribromoderivatives had the following characters:  $\alpha\beta\gamma$ -tribromobutane, b. p. 110–113°/19 mm.,  $d_4^{18}$  2.190,  $n_D^{21}$  1.5691;  $\alpha\beta\gamma$ -tribromopentane, b. p. 125–128°/21 mm.,  $d_4^{14}$  2.095,  $n_D^{18}$  1.5621;  $\alpha\beta\gamma$ -tribromohexane, b. p. 137–141°/21 mm.,  $d_4^{13}$  1.896,  $n_D^{18}$  1.5451;  $\alpha\beta\gamma$ -tribromohexane, b. p. 148–149°/27 mm.,  $d_4^{18}$  1.827,  $n_D^{18}$  1.5394. The epibromohydrins were obtained by agitating finely powdered potassium hydroxide with an ethereal solution of the bromohydrins. The *epibromohydrin* of butane- $\alpha\beta\gamma$ -triol boils at 142–144°,  $d_4^{18}$  1.468,  $n_D^{18}$  1.4685. The *epibromohydrin* of heptane- $\alpha\beta\gamma$ -triol has a pleasant anise-like odour, b. p. 202–205°, and 91°/11 mm.,  $d_4^{17}$  1.246,  $n_D^{18}$  1.4675. Butane- $\alpha\beta\gamma$ -triol and pentane- $\alpha\beta\gamma$ -triol are well characterised by their *tribenzoates*, melting at 79–80° and 99–100°, respectively. G. F. M.

**Aluminium Trialkyl Etherates.** ERICH KRAUSE and BRUNO WENDT (*Ber.*, 1923, 56, [B], 466–472).—Aluminium trialkyls have been prepared many years ago by Buckton and Odling from aluminium and mercury alkyls. In their endeavours to obtain these compounds by a more convenient process, the authors have studied the action of ethyl bromide in the presence of ethyl ether on an alloy of magnesium and aluminium containing 15.16% of the latter together with 0.24% of silicon and traces of iron and calcium under conditions similar to those usually adopted in the preparation of Grignard's reagents. When the vigorous action is completed, the ether is removed as far as possible by distillation from a water-bath and the residue is distilled under diminished pressure in an atmosphere of nitrogen, whereby the volatile aluminium compound is removed from the non-volatile magnesium derivatives. Somewhat unexpectedly, the product is found to consist of *aluminium triethyl etherate*,  $4AlEt_3 \cdot 3Et_2O$ , a colourless, mobile liquid, b. p. 112°/16 mm., which can be preserved indefinitely

in a sealed tube even if exposed to light. It decomposes very rapidly on exposure to air, but does not generally become spontaneously inflamed; it reacts explosively with water. It has b. p.  $216-218^{\circ}$ /atmospheric pressure (very slight decomp.). The composition of the product is given with some reserve owing to the exceptional experimental difficulties encountered in its analysis but the presence of ethyl ether in the product is placed beyond doubt by its actual isolation by the cautious decomposition of the etherate with water vapour and by the synthesis of the etherate from ether-free aluminium triethyl (prepared from aluminium and mercury ethyl) and ether. The etherate is more conveniently prepared in considerable quantity by the action of sublimed aluminium chloride on a solution of magnesium ethyl bromide in ether; as thus prepared, it has b. p.  $112^{\circ}/16$  mm.,  $110.5^{\circ}/13.5$  mm.,  $d_{4}^{20}$  (vac.)  $0.8200$ ,  $n_{D}^{20}$   $1.43433$ ,  $n_{D}^{25}$   $1.43700$ ,  $n_{D}^{30}$   $1.44349$ ,  $n_{H}^{20}$   $1.44884$ .

Aluminium trimethyl etherate,  $4AlMe_3 \cdot 3Et_2O$ , has b. p.  $68^{\circ}/15$  mm., and, in contrast to the ether-free compound, cannot be caused to solidify. It almost invariably inflames spontaneously on exposure to air.

Aluminium tri-n-propyl etherate,  $4AlPr_3 \cdot 3Et_2O$ , has b. p.  $135^{\circ}/18$  mm. H. W.

**Acceleration of the Hydrolysis of  $\beta\beta'$ -Dichlorodiethyl Sulphide by Alkaline Colloidal Solutions.** ROBERT E. WILSON, EVERETT W. FULLER, and MILTON O. SCHUR (*J. Amer. Chem. Soc.*, 1922, **44**, 2762—2783).— $\beta\beta'$ -Dichlorodiethyl sulphide may be completely hydrolysed by a colloidal solution of 3% of sulphonated maize oil and 2% of sodium carbonate in thirty-five minutes at  $85^{\circ}$ . The action consists in the acceleration of the rate of solution of the gas per unit area of interface. This process was used during the war in the field laundries to effect the rapid and complete removal of "mustard gas" from contaminated clothing. J. F. S.

**Action of Methyl Sulphate and Potassium Methyl Sulphate on Monocarboxylic Acids in the Absence of Water.** L. J. SIMON (*Compt. rend.*, 1923, **176**, 583—586).—Methyl sulphate and potassium methyl sulphate can in certain cases be advantageously employed for the preparation of methyl esters by direct action on the free acids themselves in absence of water according to the equations:  $CH_3 \cdot CO_2H + Me_2SO_4 = MeHSO_4 + CH_3 \cdot CO_2Me$ , and  $CH_3 \cdot CO_2H + MeHSO_4 = H_2SO_4 + CH_3 \cdot CO_2Me$ . Thus with acetic acid the first reaction occurs on heating with somewhat more than 1 mol. of methyl sulphate at  $120^{\circ}$ , and on raising the temperature to  $200^{\circ}$  when the first reaction is nearly over, the second takes place with very slight decomposition into sulphur dioxide, etc. The yield of methyl acetate exceeds 80% of the theory. Similar results were obtained with mono-, di-, and tri-chloroacetic acids, butyric acid, etc. Benzoic acid gave a smaller yield of something over 50% of the theory. The action of potassium methyl sulphate on acetic acid at about  $200^{\circ}$  gave a 70% yield of methyl acetate, and

on benzoic acid the same yield of methyl benzoate as was obtained with methyl sulphate.

G. F. M.

**Polynuclear Acetato- and Similar Kations of Barium and of Cerium.** R. WEINLAND and ALFRED HENRICHSSEN (*Ber.*, 1923, 56, [B], 528—538).—It has been shown previously by Weinland and Stroh (A., 1922, i, 981) that lead forms polynuclear kations with acetic acid. Similar salts of barium and cerium are now described, in some of which the acetato-complex is replaced by other residues. The barium acetato-compounds all appear to contain the same dibariumdiacetato-complex,  $[\text{Ba} \langle \text{CH}_3\text{CO}_2 \rangle_2 \text{Ba}]$ .

The following individual compounds are described: *Dibariumdiacetato-perchlorate acetate*,  $[\text{Ba}_2(\text{OAc})_2] \text{OAc} / \text{ClO}_4$ , transparent, rectangular plates, obtained from barium acetate and perchloric acid or sodium perchlorate in aqueous solution (the latter mode of formation appears to indicate that the dibariumdiacetato-kation is present in barium acetate); *Dibariumdiacetato-diperchlorate*,  $[\text{Ba}_2(\text{OAc})_2](\text{ClO}_4)_2 \cdot 2\text{AcOH}$ , large, transparent prisms, from barium acetate and perchloric acid in glacial acetic acid solution; *dibariumdiacetato-picrate heptahydrate*, yellow, slender rods; *dibariumdiacetato-chlorate acetate*,  $[\text{Ba}_2(\text{OAc})_2] \text{OAc} / \text{ClO}_3$ , transparent rhombohedra, from barium acetate and sodium chlorate.

The following salts contain the analogous dibariumdiformato-kation: the *nitrate*,  $[\text{Ba}_2(\text{HCO}_2)_2]_2(\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$ , large, hexagonal pyramids, obtained from barium formate and nitric acid in aqueous solution; the *perchlorate formate*,  $[\text{Ba}_2(\text{HCO}_2)_2] \text{ClO}_4 / \text{HCO}_2 \cdot \text{H}_2\text{O}$ , lustrous cubes, prepared by the spontaneous evaporation of an aqueous solution of barium formate and perchloric acid; the *picrate*,  $[\text{Ba}_2(\text{HCO}_2)_2][\text{C}_6\text{H}_2(\text{NO}_2)_3\text{O}]_2 \cdot 4\text{H}_2\text{O}$ , dark yellow prisms; the *ferricyanide potassium formate*,  $[\text{Ba}_2(\text{HCO}_2)_2][\text{Fe}(\text{CN})_6]_2 \cdot 2\text{HCO}_2\text{K} \cdot 8\text{H}_2\text{O}$ , dark red crystals, from barium formate and potassium ferricyanide; the *ferricyanide*,  $[\text{Ba}_2(\text{HCO}_2)_2][\text{Fe}(\text{CN})_6]_2 \cdot 10\text{H}_2\text{O}$ , small, dark red plates, from barium formate and sodium ferricyanide; the *cobalticyanide potassium formate*,  $[\text{Ba}_2(\text{HCO}_2)_2][\text{Co}(\text{CN})_6]_2 \cdot 2\text{HCO}_2\text{K} \cdot 8\text{H}_2\text{O}$ , pale yellow crystals; the *nitroprusside*,

$[\text{Ba}_2(\text{HCO}_2)_2][\text{Fe}(\text{CN})_5\text{NO}] \cdot 6\text{H}_2\text{O}$ , aggregates of reddish-brown leaflets.

Similar salts of cerium are described which appear to contain the triceriumtriacetato-kation. They are prepared by the action of the requisite acid on a solution of cerium acetate. Unlike the dibariumdiacetato-compounds which in certain cases can be obtained from neutral solution, the cerium compounds are only produced in a strongly acid medium. The following salts are described:

The *perchlorate acetate*,  $[\text{Ce}_3(\text{OAc})_3] \text{ClO}_4 / (\text{OAc})_4 \cdot 12\text{H}_2\text{O}$ , long, slender, colourless rods; the *picrate acetate*,  $[\text{Ce}_3(\text{OAc})_3][\text{C}_6\text{H}_2(\text{NO}_2)_3\text{O}]_3 \cdot 3\text{H}_2\text{O}$ , orange-red, rectangular plates; the *nitrate*,  $[\text{Ce}_3(\text{OAc})_3](\text{NO}_3)_6 \cdot 13\text{H}_2\text{O}$ .

pale pink, hexagonal plates which possibly owe their colour to traces of other rare earths; the *chromate*,  $[\text{Ce}_3(\text{OAc})_3](\text{CrO}_4)_3 \cdot 6\text{H}_2\text{O}$ , a yellowish-brown, microcrystalline powder; the *chloride acetate*,  $2[\text{Ce}_3(\text{OAc})_3]_{\text{OAc}}^{\text{Cl}_2} \cdot \text{Ce}(\text{OAc})_3 \cdot 28\text{H}_2\text{O}$ , colourless crystals. H. W.

**Chloroiodoacetic Acid.** HOLLAND CROMPTON and KATE MYFANWY CARTER (T., 1923, 123, 576–577).

**Trifluoroacetic Acid.** FRÉD. SWARTS (*Bull. Acad. roy. Belg.*, 1922, [v], 8, 343–370).—*p*-Aminobenzotrifluoride, on prolonged heating with chromic acid mixture, gives *trifluoroacetic acid* (70% of the theoretical quantity), which may be distilled over with water, and *hexa- $\alpha$ -fluoro-m-azotoluene*,  $\text{N}_2(\text{C}_6\text{H}_4\text{CF}_3)_2$ , orange needles, m. p.  $82.3^\circ$ , b. p.  $282^\circ$ , very volatile with steam. These two substances appear to form a compound, which is readily decomposed by sodium hydroxide. In the first stages of the oxidation (or, using permanganate), a brown, amorphous, sparingly soluble substance is formed, possibly a *quinonedianilide* of the formula  $\text{CF}_3\text{C}_6\text{H}_2\text{O}(\text{NH}\cdot\text{C}_6\text{H}_3\text{CF}_3)_2$ . Trifluoroacetic acid, obtained by distilling the sodium salt with sulphuric acid, forms rhombic plates, m. p.  $-15.25^\circ$  to  $-15.28^\circ$ , b. p.  $72.4$ – $72.5^\circ$ ,  $d^{20}_4$  1.53514, fumes in the air, has a vesicant action, and dissolves in water with evolution of heat. It forms a constant boiling mixture with water, b. p.  $105.46^\circ$ , 79.4% of acid. Degrees of dissociation for  $v=32$ , 64, and 128 are respectively 0.943, 0.966, and 0.979, giving a dissociation constant (100 *k*) of about 50. The sodium, potassium, ammonium, barium, and silver salts are described (cf. *Mem. Acad. roy. Belg.* [8vo collection], 1894–5, 51, and A., 1921, ii, 261). Trifluoroacetates give no fluoroform, and very little oxalic acid, when heated with sodium hydroxide (cf. A., 1906, i, 478).

*Ethyl trifluoroacetate*, obtained from sodium trifluoroacetate, alcohol, and sulphuric acid, has b. p.  $61.7^\circ/761$  mm.,  $d^{20}_4$  1.19529,  $n^{16}_D$  1.30783,  $n^{16}_B$  1.31237 and  $n^{16}_Y$  1.31527.

*Hexafluoroacetic anhydride*, from phosphoric oxide and trifluoroacetic acid, has m. p.  $-65^\circ$ , b. p.  $39.5$ – $40.1^\circ$ ; vapour non-associated. *Trifluoroacetamide*, leaflets, m. p.  $74.8^\circ$ , b. p.  $162.5^\circ$ , from the ethyl ester and ammonia, is volatile at ordinary temperatures. *Trifluoroacetoneitrile*, from the amide and phosphoric oxide, boils at about  $-61^\circ$ . Trifluoroacetic acid and aniline, when heated together at  $170^\circ$  give, besides *trifluoroacetanilide*, m. p.  $87.64^\circ$ , b. p.  $220$ – $225^\circ$ , a little fluoroform (cf. A., 1906, i, 159).

Sodium trifluoroacetate begins to decompose at  $205^\circ$ , giving *trifluoroacetyl fluoride*, b. p. about  $-59^\circ$ , together with some anhydride.

The paper concludes with a useful summary of the physical properties of various fluoro-derivatives of acetic acid, as compared with those of the corresponding chloro-derivatives. E. E. T.

**The Nature of Subsidiary Valency. XXVI. Complex Compounds with Sulphur Dioxide.** FRITZ EPHRAIM and CLARA AELLIG (*Helv. Chim. Acta*, 1923, 6, 37–53).—The extent

to which the alkali metal salts of fatty acids will form additive compounds with sulphur dioxide was studied using lithium, sodium, potassium, rubidium, and caesium salts of the normal fatty acids from formic to valeric, and, in addition, the benzoates. Gaseous sulphur dioxide was taken up very slowly by the salts, and the most satisfactory method of investigation was to mix the anhydrous salt with liquid sulphur dioxide and allow the excess to evaporate. The lithium salts did not form compounds. Of the formates, the sodium salt formed no compound, the potassium salt took up about  $\frac{1}{2}\text{SO}_2$  and the rubidium and caesium salt each about  $1\text{SO}_2$ . The remaining salts, including the benzoates, combined with approximately 1 mol. of sulphur dioxide. The sodium salt compounds are the least stable and gradually lose their combined sulphur dioxide in the course of a few months at the ordinary temperature. The potassium, rubidium, and caesium salts are comparatively stable up to  $70^\circ$ . At this temperature not merely loss of sulphur dioxide but more extensive decomposition takes place, and in the case of the formates free sulphur is formed. The additive compounds are white or faintly coloured with the exception of the formates, which are orange, resembling the compounds of alkali iodides with sulphur dioxide.

An investigation into the cause of the yellow colour of sodium hydrogen sulphite solutions showed that the colour is a characteristic property of the solution and not due to impurity. The colour was always obtained, using the purest materials, when sodium, potassium, or ammonium hydroxide solutions, or the solutions of their carbonates, sulphites, formates, and acetates were saturated with sulphur dioxide. To a less extent, the colour was obtained with solutions of calcium hydroxide and zinc acetate, but not with those of the chlorides, sulphates, and nitrates of the alkali metals nor with hydroxides of the alkaline-earth metals (except calcium), magnesium, or cadmium. The colour reaches its maximum when 5*N*-solutions of alkali hydroxides are saturated with sulphur dioxide, and is not perceptible below 0.5*N*. Spectroscopically, it is very similar to a dilute chromate solution. On dilution it does not follow Beer's law, but rapidly disappears. The colour may be due to the formation of complexes of the type of  $\text{KI}_4\text{SO}_2$  which in solution gives a colour three hundred times as intense as that of sodium hydrogen sulphite at the same concentration. There is insufficient evidence to afford a satisfactory explanation of the colour.

E. H. R.

#### Catalytic Decomposition of (Organic) Acids and Ketones.

A. MAHLER (*Caoutchouc et Gutta-percha*, 1922, 19, 473—475; from *Chem. Zentr.*, 1923, i, 38).—The decomposition of organic acids passed over a copper-aluminium catalyst at  $600\text{--}650^\circ$  is not of uniform type, since the products undergo further decomposition. Acids with six or less carbon atoms decompose almost completely with formation of gaseous products, water, and a small amount of ketones. From the higher acids liquids are produced which give on hydrogenation petroleum-like products including benzene

*m*\*

derivatives. Acetic acid gives carbon dioxide, carbon monoxide, methane, and hydrogen. *iso*Butyric acid gives hydrocarbons of the  $C_nH_{2n}$  and  $C_nH_{2n+2}$  series. Butyric acid gives the same products. Among the products from *isovaleric acid* is *isobutylene*. Benzene and toluene are found among the decomposition products of nonoic acid. Acetone gives carbon monoxide, methane, and hydrogen. Higher ketones give corresponding unsaturated compounds.

G. W. R.

**The Configuration of the Crotonic Acids.** K. VON AUWERS and H. WISSEBACH (*Ber.*, 1923, 56, [B], 715—733).—The literature of the various attempts to elucidate the configuration of the isomeric crotonic acids is exhaustively reviewed, and the various arguments which have been brought forward are criticised in detail. Since, in spite of the large amount of physical and chemical evidence which is available, it has not been possible to establish the configuration of the acids, the authors have endeavoured to decide the question by chemical means, using as starting point substances of known composition and utilising reactions which occur under mild conditions and do not immediately involve the doubly-linked carbon atoms of the acids, thus minimising the possibility of transformations and abnormal reactions.

The possibility of converting  $\gamma\gamma$ -trichlorocrotonic acid smoothly into maleic or fumaric acid has been examined. This cannot be accomplished satisfactorily by means of alkali, but fumaric acid is formed in excellent yield under the influence of sulphuric acid (60%) at 160—180°. The reaction in this state is unsuitable for configurative purposes, but, fortunately, the same change can be induced by concentrated sulphuric acid at the atmospheric temperature, although it occurs much more slowly; under these conditions, the formation of maleic acid cannot be detected. To permit valid conclusions as to the relationship of trichlorocrotonic and fumaric acids to be drawn from this result, it is, however, necessary to establish the stability of maleic acid under the experimental conditions. This acid is known to be very slightly isomerised by sulphuric acid, and in a series of experiments it is proved to be stable towards hydrogen chloride in the presence of concentrated sulphuric acid. Also, the formation of chlorosuccinic acid could not be established with certainty in any of the numerous experiments; according to the observations of previous works, it must have been produced in relatively considerable quantities if maleic acid had been formed. It is therefore regarded as established that  $\gamma\gamma$ -trichlorocrotonic acid is converted directly into fumaric acid and hence has the fumaroid configuration.

The replacement of the halogen atoms of  $\gamma\gamma$ -trichlorocrotonic acids by hydrogen has been investigated. This cannot be effected in the required manner by the action of sodium amalgam on the acid, of sodium or aluminium amalgam on its ethyl ester, or of sodium wire and moist ether on the amide. Zinc dust and acetic acid, however, convert the trichloro-acid or its ester into the di-

chloro-compounds, and the dichloro-acid is reducible by sodium amalgam to solid crotonic acid and a little butyric acid; the formation of isocrotonic acid is not observed. The possibility of molecular transformation during the reduction is discussed but regarded as highly improbable; solid crotonic acid is therefore to be regarded as the *trans*-form and isocrotonic acid as the *cis*-modification.

The configurations of the monohalogenated crotonic acids can now be deduced if it is granted that electrochemical differences in the molecules of organic compounds tend to become neutralised, and that addition of halogen if occurring in the *cis*-position is followed by loss of hydrogen halide in the same position and vice versa. Each crotonic acid must then form by addition of halogen and subsequent removal of the  $\beta$ -halogen atom as hydrogen halide an  $\alpha$ -halogeno-derivative of the stereoisomeric form. The configurations thus deduced are identical with those suggested by Michael and Pfeiffer from other considerations.

The annexed configurations (I) and (II) are ascribed to tiglic and angelic acids, respectively, since their relation to one another is very similar to that

between crotonic and isocrotonic acids (cf. Sudborough and Davies, *L.*, 1909, 95, 976).

The applicability of physical constants to the elucidation of the configuration of stereoisomeric compounds is discussed in detail. Melting point appears to be useful only in the cases of parent compounds since the mutual influence of substituents may completely alter the configurational relationship in the molecule. In the cases of density and refractive index, it does not invariably appear that the relative position of the groups is the decisive factor. Although a sufficiently large number of observations has not yet been made, it appears probable that the dissociation constant may be the most trustworthy physical datum. H. W.

**$\gamma\gamma\gamma$ -Trichlorocrotonic Acid,  $\gamma\gamma$ -Dichlorocrotonic Acid, and Maleinaldehydic Acid.** K. VON AUWERS and H. WISSEBACH (*Ber.*, 1923, 56, [B], 731—741; cf. preceding abstract).— $\gamma\gamma\gamma$ -Trichloro- $\beta$ -hydroxybutyric acid is obtained in approximately theoretical yield by the action of chloral hydrate on malonic acid in the presence of pyridine and is converted in the usual manner into  $\gamma\gamma\gamma$ -trichlorocrotonic acid.  $\gamma\gamma\gamma$ -Trichlorocrotonyl chloride, prepared conveniently by the action of thionyl chloride on the acid, is an almost colourless liquid, b. p.  $75^\circ/11$  mm., (i)  $d_4^{18}$  1.5292,  $d_4^{20}$  1.528,  $n_D^{18}$  1.51414,  $n_D^{18}$  1.51812,  $n_D^{18}$  1.52890,  $n_D^{18}$  1.53823,  $n_D^{17}$  1.5176; (ii)  $d_4^{17}$  1.5285,  $d_4^{20}$  1.525,  $n_D^{17}$  1.51395,  $n_D^{17}$  1.51798,  $n_D^{17}$  1.52881,  $n_D^{17}$  1.53830,  $n_D^{20}$  1.5167.  $\gamma\gamma\gamma$ -Trichlorocrotonamide crystallises in lustrous leaflets, m. p.  $83^\circ$ .  $\gamma\gamma\gamma$ -Trichlorocrotononitrile, obtained from the amide and phosphoric oxide, is a colourless liquid, b. p.  $74$ — $75^\circ/10$  mm., b. p.  $91^\circ/25$  mm.,  $d_4^{12}$  1.4319,  $d_4^{20}$  1.420,  $n_D^{12}$  1.50837,  $n_D^{12}$  1.51225,  $n_D^{12}$  1.52242,  $n_D^{12}$  1.53138,

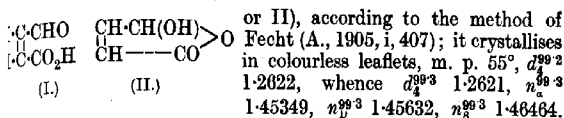

$n_D^{20}$  1.5083.  $\gamma\gamma$ -Trichlorocrotonanilide crystallises in lustrous leaflets, m. p. 162.5–163.5°.

$\gamma\gamma$ -Dichlorocrotonic acid, long, transparent, oblique prisms, m. p. 42–43°, b. p. 130°/18 mm., 123°/13 mm.,  $d_4^{20}$  1.3331, whence  $d_4^{20}$  1.3327,  $n_D^{20}$  1.45680,  $n_D^{25}$  1.45966,  $n_D^{30}$  1.46777,  $n_D^{35}$  1.47565, is readily prepared by the action of zinc dust and acetic acid on an aqueous alcoholic solution of  $\gamma\gamma$ -trichlorocrotonic acid; in consequence of the ready polymerisation of the dichloro-acid, the yields of the latter are somewhat variable but average about 60% of that theoretically possible; the reaction proceeds more smoothly if the esters are used. The ready mobility of one chlorine atom and the stability of the remaining two in the trichloro-acid is explained by Thiele's theory of partial valencies and by the assumption of residual valency of the chlorine atoms which is illus.

trated by the formula  $\begin{array}{c} \text{Cl} \\ | \\ \text{C} \\ | \\ \text{Cl} \end{array} \text{—CH=CH—C} \begin{array}{c} \text{OH} \\ | \\ \text{O} \end{array}$ .  $\gamma\gamma$ -Dichloro-

crotonic acid is converted by concentrated sulphuric acid into succinic acid in 88% yield, an aldehyde appearing to be formed intermediately. It unites readily with bromine in chloroform solution in the presence of sunlight giving  $\gamma\gamma$ -dichloro- $\alpha\beta$ -dibromobutyric acid, lustrous leaflets, m. p. 120–121°, after previous softening. Ethyl  $\gamma\gamma$ -dichlorocrotonate, prepared by reduction of the corresponding trichloro-ester, has b. p. 91°/20 mm., 82°/12 mm.,  $d_4^{16}$  1.2323,  $d_4^{20}$  1.229,  $n_D^{16}$  1.46096,  $n_D^{18}$  1.46347,  $n_D^{16}$  1.47098,  $n_D^{16}$  1.47711,  $n_D^{20}$  1.4619. It rapidly polymerises when preserved at the atmospheric temperature. It could not be caused to react with phenylhydrazine, semicarbazide hydrochloride, hydroxylamine sulphate, or sodium iodide dissolved in acetone. Ethyl  $\gamma\gamma$ -dichloro- $\alpha\beta$ -dibromobutyrate is an almost colourless liquid, b. p. 142–144°/14 mm., 158–159°/21 mm.,  $d_4^{22}$  1.8257,  $d_4^{20}$  1.830,  $\eta_{22}^{22}$  1.51936,  $\eta_{22}^{22}$  1.52233,  $\eta_{22}^{22}$  1.53096,  $\eta_{22}^{22}$  1.53787,  $\eta_{22}^{20}$  1.5235. Methyl  $\gamma\gamma$ -dichlorocrotonate is a colourless, mobile liquid, b. p. 77°/14 mm.,  $d_4^{17}$  1.3050,  $d_4^{20}$  1.302,  $n_D^{17}$  1.46744,  $n_D^{17}$  1.47040,  $n_D^{17}$  1.47811,  $n_D^{17}$  1.48442,  $n_D^{20}$  1.4694. Methyl  $\gamma\gamma$ -dichloro- $\alpha\beta$ -dibromobutyrate crystallises in transparent, quadratic plates, m. p. 37° after previous softening, b. p. 145°/19 mm.  $\gamma\gamma$ -Dichlorocrotonyl chloride is an almost colourless liquid, b. p. 66–67°/12 mm.,  $d_4^{16}$  1.4429,  $d_4^{20}$  1.442,  $n_D^{16}$  1.49547,  $n_D^{16}$  1.49928,  $n_D^{16}$  1.50818,  $n_D^{16}$  1.51674,  $n_D^{20}$  1.4991.  $\gamma\gamma$ -Dichlorocrotonamide, prepared by reduction of the trichloro-compound, crystallises in needles or leaflets, m. p. 82–83°; it is converted by bromine into  $\gamma\gamma$ -dichloro- $\alpha\beta$ -dibromobutyramide, lustrous leaflets, decomp. 162° after shrinking at 156–157°, when moderately rapidly heated.  $\gamma\gamma$ -Dichlorocrotonanilide forms long, lustrous leaflets, m. p. 83°.  $\gamma\gamma$ -Dichlorocrotononitrile is a colourless liquid with an odour of almonds, b. p. 82–83°/12 mm., 93.5–93.8°/21 mm.,  $d_4^{20}$  1.3049,  $n_D^{20}$  1.49359,  $n_D^{20}$  1.49735,  $n_D^{20}$  1.50714,  $n_D^{20}$  1.51500.

$\gamma$ -Hydroxy- $\Delta^6$ -crotonolactone is converted into maleinaldehydeic acid or 2-keto-5'-hydroxy-3:4-dihydrofuran (annexed formula, I

The optical data indicate that the cyclic form is mainly present in the molten substance. The corresponding *p*-nitrophenylhydrazone as m. p. 221° or (+EtOH), m. p. 211–212°. The aldehyde is decomposed by concentrated sulphuric acid without appearing to yield definite products; the formation of succinic acid could not be observed.

H. W.

**The Preparation and Constitution of Synthetic Fats containing a Carbohydrate Chain.** HELEN S. GILCHRIST (*Rep. Brit. Assoc.*, 1922, 357).—When  $\alpha$ -methylglucoside is heated with olive oil in the presence of sodium ethoxide, a mono-oleate of  $\alpha$ -methylglucoside is first formed, whilst in the case of mannitol di-oleate is formed. In each case, internal dehydration follows at once, the carbohydrate chain losing one molecule of water and the fatty residues remaining intact. Anhydromethylglucoside mono-oleate and mannitol di-oleate are definite chemical individuals. On methylation, they yield unstable monomethyl derivatives. When heated with acidified alcohol, they give methyl oleate together with an alkylated sugar derivative. In both cases the anhydro-ring persists during hydrolysis.

**Hydrogenation and Dehydrogenation of Castor Oil and its Derivatives.** ANDRÉ BROCHET (*Compt. rend.*, 1923, 176, 513–515; cf. Mailhe, this vol., i, 88).—Castor oil is completely hydrogenated under a pressure of eleven atmospheres in the presence of reduced nickel at 112–114° in ninety minutes. The hydrogenated oil has m. p. 86° and iodine number 2. When heated in an open flask, it begins to give off hydrogen at 150°, and the volume liberated increases with rise in temperature up to about 280°. The original castor oil absorbs 70 c.c. of hydrogen per gram, but the hydrogenated oil only gives off 40 c.c. per gram. Methyl ricinoleate is hydrogenated in the same manner as castor oil and absorbs the theoretical amount of hydrogen in less than an hour at 100–105° under a pressure of twelve atmospheres.

W. G.

**A New Tetradecenoic Acid from Sperm and Dolphin Oils.** MITSUMARU TSUJIMOTO (*Chem. Umschau*, 1923, 30, 33–36).—A tetradecenoic acid,  $\text{C}_{14}\text{H}_{26}\text{O}_2$ , was isolated from sperm oil by converting the glycerides into methyl esters, separating the fraction boiling up to 180°/15 mm., brominating, and refractionating the bromo-esters, whereby a fraction boiling at 132–136°/5 mm. was obtained. This was debrominated by means of zinc and acetic acid, and saponified, non-saponifiable matter was removed by extraction with ether, and the fat acid was liberated by the addition of mineral acid. It formed a colourless liquid boiling between 190° and 200°/15 mm.,  $d_4^{15} 0.9079$ ,  $n_D^{15} 1.4566$ , iodine value 106.8. On hydrogenation it was converted into myristic acid,

and on oxidation gave a *dihydroxy-myristic acid*,  $C_{14}H_{28}(OH)_2O_2$ , m. p. 118–119°. The latter acid on oxidation with dichromate and sulphuric acid gave a reaction product from which nonoic acid was isolated. Only a very small amount of a substance which probably represented the corresponding scission product, glutaric acid, was obtained, but the results so far obtained indicate that the tetradecenoic acid is probably the  $\Delta^8$ -compound,

Tetradecenoic acid was also isolated from the low boiling fraction of the methylated sperm oil by the lead salt–light petroleum method, and from dolphin oil by the above bromination method. The yield from sperm oil was about 3% and from dolphin oil about 0.4%.

**A New Substance in Birch Tar.** I. K. TRAUBENBERG (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 153–156).—*Dokozanic acid*,  $C_{21}H_{42}O_2$  or  $C_{22}H_{44}O_2$ , lustrous leaflets, m. p. 72°, is found to the extent of 0.4% in birch tar; it is a fatty acid, similar in appearance and properties to stearic acid. The silver and sodium salts are prepared and described. The product of oxidation with nitric acid is an acidic substance, m. p. 67°, of the formula  $C_{22}H_{44}O_3$ , and is probably a hydroxy acid.

R. T.

**Pyruvic Acid from Lactic Acid.** J. G. SMULL and P. SUBROW (*Chem. and Met. Eng.*, 1923, 28, 357–358).—By electrolytic oxidation of lactic acid in acid, alkaline, or neutral electrolytes in a divided cell it was found that pyruvic acid was not formed when a platinum anode was used unless substances were present which removed the pyruvic acid immediately from the sphere of oxidation. Better yields were obtained by the use of a lead anode and an alkaline anolyte, but the efficiency of the process is low (cf. *J.S.C.I.*, 1923, April).

**Inorganic Complex Salts. II. Erdmann's Salt and its Derivatives.** WILLIAM THOMAS (*T.*, 1923, 123, 617–619).

**Complex Metallic Ammines. VIII. The Introduction of Di- and Tri-basic Organic Acid Radicles into the Pentamminecobaltic Complex.** JAMES COOPER DUFF (*T.*, 1923, 123, 560–575).

**isoPropylmalonic Acid Derivatives and Steric Hindrance.** E. PREISWERK (*Helv. Chim. Acta*, 1923, 6, 192–198).—The effect of the *isopropyl* group on the reactivity of substituents in its proximity is often attributed to steric hindrance, but a study of the influence of the group in three compounds, ethyl *isopropyl*malonate, ethyl *isopropyl*cyanoacetate [ethyl  $\alpha$ -cyano- $\beta$ -methylbutyrate], and *isopropyl*barbituric acid, proves that this explanation does not always hold. In each of these cases the carbon atom to which the *isopropyl* group is attached carries a reactive hydrogen atom, which can, in general, be substituted by an alkyl group. Ethyl *isopropyl*malonate cannot be alkylated at all,

although the corresponding ethylmalonate and *n*-propylmalonate can be alkylated. In the case of the derivatives of ethyl cyanoacetate, the *isopropyl* derivative can be alkylated as readily as any other alkyl derivative. More remarkable than this is the observation that *isopropylbarbituric acid* can be alkylated more readily than either ethyl- or *n*-propyl-barbituric acid.

The ease with which these substances can be alkylated may be taken to depend on their acidity. Barbituric acid is a comparatively strong acid, stronger than acetic, and is not easily alkylated, on account of the stability of its alkali salts. The *C*-alkylated barbituric acids are less strongly acidic, especially the *isopropyl* derivative, which is weaker than acetic acid. By weakening the acidic properties, the alkyl groups facilitate alkylation.

In the case of ethyl cyanoacetate, the weakening of acidity due to the introduction of alkyl groups is unimportant. Ethyl malonate is the most feebly acidic of the substances under consideration and in its alkyl derivatives the acidity becomes so weak that the labile hydrogen atom loses its reactivity altogether. This explains why ethyl *isopropylmalonate* cannot be alkylated.

*Methylisopropylbarbituric acid*, obtained by methylating *isopropylbarbituric acid* in sodium hydroxide solution with methyl iodide, forms colourless crystals, m. p. 186–187°. *isopropylallylbarbituric acid* forms colourless crystals, m. p. 137–138°. *Diisopropylbarbituric acid* forms colourless crystals, m. p. 230° (decomp.).

E. H. R.

**Effect of Molybdic Acid and of Molybdates on the Rotatory Power of Malic Acid.** E. DARMOIS (*J. Phys. Radium*, 1923, 4, 49–70).—A historical résumé is given of the work of Gernez and others on the effect of alkali molybdates and tungstates on the rotatory powers of malic and tartaric acids. The author has investigated more especially the effect of ammonium and sodium molybdates on the rotatory power of malic acid. Solutions were prepared by adding ammonia or sodium hydroxide to aqueous solutions containing *n* gram-molecules of molybdic acid and 1 gram-molecule of malic acid, *n* ranging from 0 to 5, and the rotatory powers for  $\lambda\lambda$  5780, 5460, and 4360 Å. measured. Curves showing the relation of the rotatory power to *n*, for various concentrations of sodium hydroxide or ammonium, all possess respective maxima. The largest dextrorotatory power measured in each case corresponded with *n*=2, and characterised solutions containing 2 gram molecules of either ammonia or sodium hydroxide to 1 of malic acid. The results of Gernez indicating the existence of solutions having maxima of *lævo*- and *dextro*-rotations and the results of the present investigation are explicable on the assumption of the existence of definite compounds, the dimolybdomalates, *e.g.*,  $2\text{MoO}_3 \cdot \text{C}_4\text{H}_6\text{O}_5 \cdot 2\text{NaOH}$ , and  $2\text{MoO}_3 \cdot \text{C}_4\text{H}_6\text{O}_5 \cdot 2\text{NH}_3$ , and of molybdomalates, *e.g.*,  $\text{MoO}_3 \cdot 2\text{C}_4\text{H}_6\text{O}_5 \cdot 2\text{NaOH}$ . Crystals of sodium dimolybdomalate are monoclinic and exist as hemihedral enantiomorphs [ $a : b : c = 1.442 : 1 : 1.939$ ,  $\beta = 97^\circ 46'$ ]. Barium dimolybdo-

malate has been prepared in the form of well defined crystals. Values of the respective rotatory and dispersive powers are given.

J. S. G. T.

***d*-Malic Acid and the Utilisation of Ammonium Molybdomalate for the Decomposition of *r*-Malic Acid.** E. DARMOIS and J. PÉREL (*Compt. rend.*, 1923, 176, 391—394).—*r*-Ammonium molybdomalate is not deposited from its solution as such, but gives a mixture of crystals of the *d*- and *l*-salts, which may be separated mechanically. The optical rotation of these salts is of such a magnitude,  $[\alpha]_{578} \pm 220^\circ$ , that it is possible very readily to determine the purity of the resulting isomerides. The active molybdomalates may readily be converted into the active malic acids by decomposition with hydrogen sulphide in the presence of nitric acid, the malic acid being precipitated as its lead salt after filtering off the molybdenum sulphide. The lead salt is then decomposed by hydrogen sulphide. The preparation of *d*-malic acid from the natural *l*-acid by the Walden inversion gives a mixture of 75% of the *d*-acid and 25% of the *l*-acid, partial racemisation occurring during the inversion.

W. G.

**The Formation of Derivatives of Oxalacetic Acid from Tartaric Acid.** FREDERICK DANIEL CHATTAWAY and GEORGE DAVID PARKES (*T.*, 1923, 123, 663—669).

**Complex Aluminium Salts of Aliphatic Hydroxy-acids.** OSKAR GOLDMAN (*Biochem. Z.*, 1922, 133, 459—468).—The following salts of aluminium and an organic acid have been obtained: aluminium hydrogen tartrate,  $\text{Al}(\text{C}_4\text{H}_5\text{O}_6)_3$ ; ammonium hydrogen aluminotartrate,  $\text{C}_6\text{H}_{15}\text{O}_{12}\text{N}_2\text{Al}$ ; aluminotartaric acid, potassium aluminotartrate,  $\text{C}_8\text{H}_7\text{O}_{12}\text{K}_2\text{Al}$ ; sodium aluminotartrate,  $\text{C}_{12}\text{H}_9\text{O}_{15}\text{Na}_6\text{Al}$ ; an aluminium mucate,  $\text{C}_6\text{H}_7\text{O}_8\text{Al}$ ; ammonium aluminomucate,  $\text{C}_6\text{H}_{13}\text{O}_8\text{N}_2\text{Al}$ ; sodium aluminomucate,  $\text{C}_6\text{H}_5\text{O}_8\text{Na}_2\text{Al}$ . Constitutional formulæ are suggested.

W. O. K.

**Preparation of Formaldehyde.** P. BOBROV (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 130—136).—The yields of formaldehyde obtained by passing a mixture of methyl alcohol vapour and air through a heated tube containing copper gauze spirals as catalyst are usually 37—42% of theory. By using instead of spirals copper gauze disks packed perpendicularly to the axis of the tube, the yields were increased to 67.6—71.6% of theory. The presence of acetone up to 4% in the spirit does not materially affect the reaction. The use of copper, gold, and silver finely distributed on asbestos, as catalysts, in conjunction with the copper disks, is tried, using spirit mixed with acetone, the amount of the latter being gradually increased to 11%. Under these conditions, copper catalyst gives yields of 70.04—72.4%, gold gives 72.79%, and silver 77.73% of the theoretical. Variations in the temperature of the alcohol vapour affect the yields less than when copper disks alone are used. On the other hand, gold and silver soon lose their catalytic power, probably owing to their relative volatility in these circumstances, which gives rise, eventually, to the formation of a

metallic mirror in the tube. Pure methyl alcohol with silver catalyst gives yields of 89.5%. The formaldehyde thus obtained, however, almost immediately polymerises to a hard, white solid, which condenses in the cooler parts of the tube, blocking it, so that the process cannot continue to the end.

R. T.

**Catalysis in the Preparation of Acetal.** HOMER ADKINS and BRYNJULV H. NISSEN (*J. Amer. Chem. Soc.*, 1922, 44, 2749—2755).—Calcium, lithium, magnesium, cerium, ammonium, manganese, and zinc chlorides, calcium nitrate, calcium bromide, copper sulphate, sodium and lithium iodides act as true catalysts and not merely as dehydrating agents in the preparation of acetal from alcohol and acetaldehyde. Acetal is best prepared by placing 200 g. of anhydrous calcium chloride and 1050 g. of 95% alcohol in a 4-litre bottle and cooling to 8° or less. Five hundred g. of cold acetaldehyde are poured slowly down the inside wall of the bottle to form a layer on the alcohol. The bottle is closed and shaken intermittently for twelve hours. After settling, the clear upper layer is separated and washed three times with water, allowed to settle, dried, fractionated, etc. Following the procedure fully detailed in the paper, a total yield of 64% can be obtained. The equilibrium point of the equation  $\text{CH}_3\cdot\text{CHO} + 2\text{EtOH} \rightleftharpoons \text{CH}_3\cdot\text{CH}(\text{OEt})_2 + \text{H}_2\text{O}$  in the presence of calcium chloride lies at 76% of acetal. Acetal has  $d_4^{20}$  0.8254,  $d_{15}^{15}$  0.8334;  $n_D^{25}$  1.3682. Its vapour pressure and solubility in water and alcohol have been determined over a wide range of temperature. The following values of the vapour pressure are recorded: 33°, 52 mm.; 52.8°, 121 mm.; 62°, 178 mm.; 71°, 244 mm.; 81.7°, 365 mm.; 90.5°, 499 mm.; 95.1°, 586 mm.; 101.2°, 720 mm.; 103°, 745 mm., and 104.2°, 760 mm.

J. F. S.

**Synthesis of  $\alpha$ -Dihydroxyhexaldehyde and its Methyl Semiactal.** BURCKHARDT HELFERICH and ARNO RUSSE (*Ber.*, 1923, 56, [B], 759—766).—The synthesis of the aldehyde is described. The main interest of the work lies in the observation that the presence of two hydroxy-groups in the  $\alpha$ - and  $\gamma$ -positions of an aldehyde is sufficient for the production of two isomeric semi-acetals; under the same or similar conditions, this does not appear to be the case with  $\gamma$ -hydroxyaldehydes.

$\alpha$ -Diketoheptaldehydediethylacetal,  $\text{CH}_3\text{Me}\cdot\text{CO}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{CH}(\text{OEt})_2$ , is prepared by the action of sodium ethoxide on a mixture of diethoxyacetic ester and methyl ethyl ketone. It is a colourless, mobile liquid, b. p. 110—116°/10 mm.,  $d_4^{18}$  1.0102,  $n_D^{18}$  1.4505; the copper salt,  $\text{C}_{20}\text{H}_{34}\text{O}_8\text{Cu}$ , m. p. 115°, is described. When reduced by sodium amalgam, the aldehyde combines with only one molecular proportion of water, yielding hydroxyketo- $\alpha$ -hexaldehydediethylacetal, a viscous, pale yellow liquid, b. p. 110—120°/3.5 mm.,  $d_4^{18}$  1.0040,  $n_D^{18}$  1.4401.

Methyl dimethoxyacetate, a mobile, colourless liquid, b. p. 61—64°/12 mm.,  $d_4^{18}$  1.0962,  $n_D^{18}$  1.4045, is prepared by the action of methyl-alcoholic sodium methoxide on potassium dichloroacetate

followed by esterification of the product with methyl-alcoholic hydrogen chloride. It condenses with methyl ethyl ketone in the presence of sodium methoxide to give  $\alpha$ -diketo-n-hexaldehydedimethylacetal, a colourless, mobile liquid, b. p. 100–106°/11 mm.,  $d_4^{20}$  1.0660,  $n_D^{20}$  1.4574, which yields a dark blue monohydrated copper salt, m. p. 72°, and a dark green, anhydrous copper compound, m. p. 78°. It is reduced by sodium amalgam in alkaline solution in the presence of ammonium chloride to  $\alpha$ -dihydroxy-n-hexaldehydedimethylacetal,  $\text{CH}_3\text{Me}\cdot\text{CH}(\text{OH})\cdot\text{CH}_2\cdot\text{CH}(\text{OH})\cdot\text{CH}(\text{OMe})_2$ , a pale yellow, viscous liquid, b. p. 112–120°/3 mm.,  $d_4^{21}$  1.0407,  $n_D^{18}$  1.4460, which is hydrolysed by N/10-sulphuric acid at the atmospheric temperature to  $\alpha$ -dihydroxy-n-hexaldehyde, a pale yellow, moderately mobile liquid, b. p. 95–107.5°/0.5 mm.,  $d_4^{20.5}$  1.0927,  $n_D^{18.5}$  1.4564; the aldehyde yields amorphous products with phenylhydrazine or its p-nitro-derivative. The di-methylacetal is transformed by well-cooled, methyl-alcoholic hydrogen chloride (1%) into the corresponding semiacetal A (?),

a colourless, mobile liquid, b. p. 103–109.5°/12 mm.,  $d_4^{22.5}$  1.0510,  $n_D^{20.7}$  1.4375, and by methyl-alcoholic hydrogen chloride (0.25%) at 100° into the semiacetal B (?),  $\text{CH}_3\text{Me}\cdot\text{CH} < \begin{matrix} \text{O} \\ \text{CH}\cdot\text{OMe} \\ \text{CH}_2\cdot\text{CH}\cdot\text{OH} \end{matrix}$ , a mobile, colourless liquid, b. p. 102–115°/13–15 mm.,  $d_4^{20}$  1.0246,  $n_D^{20.6}$  1.4379. The isomerides differ from one another to some extent in odour, taste, and solubility in water, but mainly in the differing rate of hydrolysis by N/100-sulphuric acid. They are not hydrolysed by  $\alpha$ -glucosidase from yeast or by emulsin. H. W.

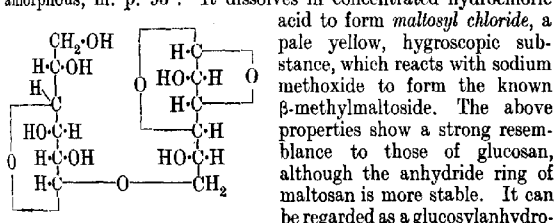

**The Hydration of Dialkylethinylcarbinols and the Preparation of  $\alpha$ -Hydroxymethyl Ketones.** RENÉ LOCQUIN and SUNG WOUSSENG (*Compt. rend.*, 1923, 176, 516–518).—The method of preparing methyl  $\alpha$ -hydroxyisopropyl ketone from methylbutinenol by the action of mercuric sulphate in dilute sulphuric acid (cf. Scheibler and Fischer, A., 1922, i, 1108), is generally applicable for the preparation of such methyl  $\alpha$ -hydroxyalkyl ketones from dialkylethinylcarbinols. The following new ketones have been prepared in this way.  $\gamma$ -Ethylpentane- $\gamma$ -ol- $\beta$ -one,  $\text{OH}\cdot\text{CET}_2\cdot\text{COMe}$ , b. p. 56–57°/13 mm., and 163–165°,  $d_4^{21}$  0.9353,  $n_D^{21}$  1.4303, giving an oxime, b. p. 116–118°, a semicarbazone, m. p. 155–156°, and an acetate, b. p. 87–90°, the semicarbazone of which has m. p. 145–146°.  $\gamma$ -Propylhexane- $\gamma$ -ol- $\beta$ -one,  $\text{OH}\cdot\text{CPr}_2\cdot\text{COMe}$ , b. p. 86–88°/14 mm., and 195°,  $d_4^{21}$  0.9124,  $n_D^{21}$  1.4343, giving an oxime, b. p. 134–135°/11 mm., m. p. 67°, a semicarbazone, m. p. 163°, and an acetate, b. p. 107–109°/13 mm.  $\beta\beta$ -Trimethylpentane- $\gamma$ -ol- $\delta$ -one,  $\text{CMe}_3\cdot\text{CMe}(\text{OH})\cdot\text{COMe}$ , b. p. 70–72°/14 mm., and 177°,  $d_4^{21}$  0.9388,  $n_D^{21}$  1.4442, giving an oxime, b. p. 124°/12 mm., m. p. 67–68°, and a semicarbazone, m. p. 193–194°.  $\gamma$ -Nonylbutane- $\gamma$ -ol- $\beta$ -one,  $\text{C}_8\text{H}_{17}\cdot\text{CMe}(\text{OH})\cdot\text{COMe}$ , b. p. 146–147°/12 mm.,  $d_4^{21}$  0.8941,  $n_D^{21}$  1.4472, giving a semicarbazone, m. p. 131–132°. 1-Acetylcyclohexan-1-ol, b. p. 91°/11 mm.,  $d_4^{21}$  1.1033,

$n_D^{20}$  1.4726, giving an *oxime*, b. p. 146–147°/11 mm., m. p. 94–95°, and a *semicarbazone*, m. p. 217°. W. G.

**Researches on Residual Affinity and Co-ordination. XV. Interactions of Acetylpropionylmethane and the Tetrachlorides of Selenium and Tellurium.** GILBERT T. MORGAN and HARRY GORDON REEVES (T., 1923, 123, 444–452).

**The Influence of Dextrins on the Crystallisation of Maltose.** L. DE HOOP and M. J. VAN TUSSENBROCK (*Biochem. Z.*, 1923, 135, 217–223).—In the commercial diastatic hydrolysis of starch, a maltose syrup is obtained which cannot be caused to crystallise directly. The authors have sought to discover the cause by determining the influence exerted by various substances, such as dextrins, proteins, peptones, and amino-acids on the crystallisation of pure maltose. It is found premature to attribute the lack of crystallising power of maltose syrup to dextrins. H. K.

**Maltosan.** AMÉ PICTET and ANDRÉ MARFORT (*Helv. Chim. Acta*, 1923, 6, 129–133).—When maltose is slowly heated to 160° under reduced pressure (15 mm.) it is converted into an anhydride, *maltosan*,  $C_{12}H_{20}O_{10}$ , forming a brown, amorphous powder which cannot be crystallised. It has no sharp m. p. but becomes viscous at 120° and liquid at 145–150°;  $[\alpha]_D^{20} +75.6^\circ$ . It cannot be distilled, and is not hydrated to maltose when boiled for a prolonged period with water. It reduces Fehling's solution at the boiling temperature, its reducing power being equal to that of maltose, and with phenylhydrazine it forms maltosazone. It reduces cold neutral potassium permanganate and is fermented by brewer's yeast. It forms a *hexa-acetyl* derivative,  $C_{24}H_{32}O_{16}$ , amorphous, m. p. 95°. It dissolves in concentrated hydrochloric

acid to form *maltosyl chloride*, a pale yellow, hygroscopic substance, which reacts with sodium methoxide to form the known  $\beta$ -methylmaltoside. The above properties show a strong resemblance to those of glucosan, although the anhydride ring of maltosan is more stable. It can be regarded as a glucosylanhydro-

glucose of the formula shown. Maltosan remains unchanged under conditions which cause polymerisation of the hexosans, such as heating with zinc chloride. E. H. R.

**The Preparation of Xylose from Maize Cobs.** ARTHUR ROBERT LING and DINSHAW RATTONJI NANJI (T., 1923, 123, 620–621).

**Swelling of Starch and the Coagulation of Albuminoids by Heat.** W. W. LEPESCHKIN (*Kolloid Z.*, 1923, 32, 42–44).—The swelling of starch is shown to be due to hydration with the formation of amylopectin. Every variety of starch has not its

own swelling temperature; this process is a chemical reaction and as such is dependent on the temperature. The temperature coefficient is extraordinarily high, and is estimated at  $57 \times 10^4$ — $83.9 \times 10^4$ . Similarly the coagulation of proteins is a chemical reaction and consists in the withdrawal of water from the molecule. This process is also dependent on the temperature and has a temperature coefficient of  $58 \times 10^3$ — $95.4 \times 10^3$ . These very high temperature coefficients are explained as due to the cumulative effects of the acceleration of the rate of diffusion, increased solubility, and increased velocity of the actual reactions.

J. F. S.

**The Starch-Iodine Complex. II.** L. BERZELLER (*Biochem. Z.*, 1922, 133, 502—508; cf. A., 1918, i, 101).—The compound formed between iodine and starch is considered to be an adsorption compound. Less iodine is taken up from alcohol than from water, and none from benzene or carbon tetrachloride, and this agrees with experimental results obtained with adsorbing charcoal. Measurements made of the adsorption of iodine by starch solution, by determination of the partition coefficient (between the starch solution and tetrachloroethane), or by dialysis, show that less is adsorbed than by solid starch.

W. O. K.

**The Limiting Dextrin formed by the Diastatic Degradation of Starch.** C. J. LINTNER and MAX KIRSCHNER (*Z. angew. Chem.*, 1923, 36, 119—122).—Achroodextrin II (cf. Lintner and Düll, A., 1895, i, 409), formed together with maltose by the action of diastase on starch, forms a dibenzoate and a diacetate and is attacked by neither emulsin nor *Saccharomyces Pombé*, but is converted quantitatively into dextrose by taka-diastase and completely fermented by the simultaneous action of diastase and yeast. Compounds intermediate between maltose and achroodextrin II, such as maltodextrins (cf. Brown and Millar, T., 1899, 286, 315), are not formed by the purely diastatic degradation of starch, and where they occur, as in beer, they must result from the action of maltase (cf. *J.S.C.I.*, 1923, April).

T. H. P.

**The Constitution of Polysaccharides. The Molecular Structure of Cotton Cellulose.** JAMES COLQUHOUN IRVINE and EDMUND LANGLEY HIRST (T., 1923, 123, 518—532).

**The Absorption of Sodium Hydroxide Solutions by Cotton.** HUBERT FRANK COWARD and LEO SPENCER (*J. Text. Inst.*, 1923, 14, T. 32—45).—In order to throw some light on the question whether mercerisation is a chemical or physical phenomenon, the authors have determined the composition of the solid phase when purified cotton is immersed in sodium hydroxide solutions of various concentrations, and when cotton so treated is subsequently washed in more dilute solutions of alkali or in water. The measurements made were the weight of the dried cotton (steam oven), the weight of the centrifuged mass (seven and a half minutes at 7000 revolutions per minute; see following abstract), and the weight of sodium hydroxide absorbed, as determined by titration. The temperature was 15—18°. The curves obtained for sodium

hydroxide absorbed, over the whole range of solubility of the alkali, are complex and give no indication of the formation of definite chemical compounds, neither are they of the form commonly found for simple adsorption. However, the ratio of alkali absorbed to water absorbed is greater than the ratio of alkali to water in the original solution, and this preferential absorption is approximately proportional to the concentration of the solution in contact with the cotton. The shape of the curves in this case also does not give direct evidence of the formation of definite compounds, but it is not inconsistent with the view that a series of compounds,  $(C_6H_{10}O_5)_m(NaOH)_n$ , is formed.

The volume of the absorbed solution has also been taken as a measure of the swelling of the hairs. It appears that swelling increases up to a limiting concentration of about 14.3% sodium hydroxide, when it remains constant, the hair having become about three times its original size. This limitation is imposed by the cuticle of the hair, since the contents are capable of even twelve-fold expansion. In the case of fabrics, the maximum swelling is much less, because of the mechanical constraints, and this, and similar phenomena connected with swelling, are discussed in the light of their practical significance in mercerising and dyeing.

J. C. W.

**The Efficacy of a Centrifuge for Removing Surface Liquids from Cotton Hairs.** HUBERT FRANK COWARD and LEO SPENCE (J. Text. Inst., 1923, 14, T. 29—32).—The centrifuge employed could be driven at 8000 revolutions per minute, or with an acceleration 2900 times that of gravity. Comparing the rates of removal of various liquids from cotton and glass wool, it is found that a few minutes' centrifuging, with an acceleration about 2000 times that of gravity, suffices to remove interfibrillar liquid down to 5 or 10% of the weight of the dry fibres, except in the case of very viscous liquids such as castor oil. Since, however, cotton retains water of the order of 50% of its weight, and sodium hydroxide solutions up to nearly 300%, under the above conditions, it follows that these liquids are held within the body of the cotton hairs to substantially the amount left after centrifuging as described. This is supported by the fact that cotton hairs swell considerably when immersed in water or sodium hydroxide solutions, but scarcely alter in liquids like alcohol or xylene.

J. C. W.

**Theory of the Solvent Action of Aqueous Solutions of Neutral Salts on Cellulose.** HERBERT E. WILLIAMS (Mem. Manchester Phil. Soc., 1921, 65, No. 12, 1—13).—The solution of cellulose in an aqueous solution of a neutral salt is independent of the chemical nature of the salt, but it is largely dependent on the physical properties of the salt solution. For such a solution to dissolve cellulose it must contain a hydrate, that is, an associated molecular complex of the salt and water. But this complex must be of such an order that it has a viscosity above a certain minimum, and a positive heat of dilution between well-defined limits. These limiting conditions will vary according to the nature of the cellulose

and the treatment which it has undergone; but for any particular cellulose the limits will be constant for all salt solutions in water.  
J. F. S.

**The Action of Acetyl Bromide on Cellulose.** LÁSZLÓ ZECHMEISTER (*Ber.*, 1923, 56, [B], 573—578; cf. Bergmann and Beck, A., 1921, i, 649; Hess, A., 1922, i, 12; Karrer, A., 1921, i, 311, 766, 768; Zechmeister, *Diss.*, Zürich, 1913).—It does not appear to be possible to convert intact or nearly intact cellulose by means of acetyl bromide into acetylbromo-derivatives. The material behaves indifferently towards the reagent, acetylation or introduction of the bromine atom only occurring to a marked extent as it passes into solution, becoming thereby considerably degraded. Hydrogen bromide and acetic acid which are invariably present in technical acetyl bromide have a very important accelerating action on the acetolysis of cellulose. If the reagent is purified by being distilled over bright calcium turnings, its attack is very greatly delayed.

By the cautious addition of water to acetyl bromide, it is possible to hydrolyse it to any desired extent; it is found that with increasing hydrolysis its action becomes increasingly energetic. The course of the change is followed by analysis of the products which can be precipitated with water, since the undissolved fibres are not appreciably affected and the soluble products are difficult to determine. In the initial stages of the change, fission of the cellulose molecule appears to be initiated by hydrogen bromide, after which the disengaged hydroxyl groups become acetylated. Hydrogen bromide is thereby liberated which further hastens the general degradation. Hand in hand with the step-wise conversion into derivatives of simpler carbohydrates there occurs a partial displacement of the acetyl groups by the bromine atom, which resembles the conversion of dextrose penta-acetate into acetylbromoglucose.

Starch is converted by technical acetyl bromide into acetobromoglucose; the yields are, however, poor, and the conversion is effected more readily by acetyl bromide and a large excess of hydrogen bromide (cf. Bergmann and Beck, *loc. cit.*). It is remarkable that pine wood is soluble without residue in technical acetyl bromide (cf. Karrer and Widmer, A., 1921, i, 771). H. W.

**[Cellulose Copper Compounds.]** KURT HESS and ERNST MESSMER (*Ber.*, 1923, 56, [B], 587—591; cf. A., 1921, i, 401; 1922, i, 988).—A reply to the recent criticisms of Traube (this vol., i, 186). H. W.

**Nature of the Swelling Process. VII. Molecular Processes during Swelling and the Heat of Swelling.** E. KNOEVENAGEL and E. VOLZ (*Koll. Chem. Beihefte*, 1923, 17, 51—71; cf. A., 1921, i, 420, 709, 710, 771; this vol., i, 17).—A continuation of previously published work. The swelling of cellulose acetate in binary mixtures of alcohol, nitrobenzene, and benzene has been investigated for a large number of binary mixtures of

various compositions. The results show that the liquid is adsorbed by the cellulose acetate in molecular proportions. The number of molecules of alcohol, benzene, or water adsorbed bears a constant relationship to the number of molecules of cellulose acetate, and where binary liquid mixtures of varying composition are used the sum of the number of molecules of each liquid taken up in the swelling is constant. The heat change occasioned by the swelling of cellulose acetate in the same binary mixtures has also been determined. The results although complicated by the nature of the process clearly indicate that the heat change has a molecular relationship.

J. F. S.

**Graphic Representation of the Decomposition of Mono-, Di-, and Tri-methylamine Gas Mixtures.** RUDOLF MICHEL (*Chem. Ztg.*, 1923, 47, 173—174).—A method is developed for the graphic representation of the thermal decomposition of the methylamines into hydrogen cyanide, ammonia, methane, hydrogen, and carbon. All the possible ways in which this may occur are summed up in the three following fundamental equations: (1)  $\text{NH}_2\text{Me} = \text{NH}_3 + \text{H}_2 + \text{C}$ ; (2)  $\text{N}(\text{CH}_3)_2 = \text{HCN} + 2\text{CH}_4$ , and (3)  $\text{N}(\text{CH}_3)_3 = \text{HCN} + 4\text{H}_2 + 2\text{C}$ , and the gas mixtures formed are represented each by a corner of a Gibbs triangle, every point within the triangle thus representing one of the possible mixtures of gases which may arise from the decomposition of a methylamine mixture. The thermochemical relationships are also expressed by means of a Gibbs triangle in a similar way.

**Researches on Pseudo-bases. IV. A New Synthesis of Tertiary Amines of the Form  $\text{R}\cdot\text{CH}_2\cdot\text{NR}^1\text{R}^2$ .** GERTRUDE MAUD ROBINSON and ROBERT ROBINSON (*T.*, 1923, 123, 532—543).

**Perhalides of Quaternary Ammonium Salts.** FREDERICK DANIEL CHATTAWAY and GEORGE HOYLE (*T.*, 1923, 123, 654—662).

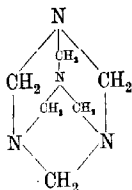

**The Complex Ions formed by Silver Salts and Ethylenediamine in Aqueous Solution.** P. JOB (*Compt. rend.*, 1923, 176, 442—445).—The silver-ion forms with ethylenediamine, in a dilute aqueous solution of the silver salt, two complex ions of the types  $\text{Ag en}_2$  and  $\text{Ag en}$ , where en represents a molecule of ethylenediamine. The second complex only exists in any appreciable quantity when the concentration of the diamine is very small. The equilibrium constants of the two ions are  $K = 6.8 \times 10^7$  and  $k = 10^5$ , respectively, at 16°. The affinities of the silver-ion for ethylenediamine are in normal solution given by

The second value coincides almost exactly with the value calculated by Bodländer (*A.*, 1904, ii, 122) for the affinity of silver for ammonia.

W. G.

**Crystal Structure of Hexamethylenetetramine.** ROSCOR G. DICKINSON and ALBERT L. RAYMOND (*J. Amer. Chem. Soc.*, 1923, 45, 22—29).—Crystals of hexamethylenetetramine have been examined by X-ray methods, using spectral photographs and Laue photographs. The data thus obtained have been accounted for by a structure with tetrahedral symmetry which may be regarded as built up of like molecules of  $C_6H_{12}N_4$  in parallel orientation and on a body-centred cubic lattice of edge 7.02 Å. Both the carbon

atoms and the nitrogen atoms are equivalent among themselves. This fact is not shown by any of the structural formulæ hitherto put forward for this substance, but is in keeping with the annexed formula. Two nitrogen atoms are at a distance of about 1.44 Å. from each carbon atom, and at least approximately in the direction of two vertices of a tetrahedron, which is in agreement with the accepted view of the tetrahedral nature of the carbon atom. J. F. S.

**Compounds of Normal Salts with Amino-acids and Polypeptides.** PAUL PFEIFFER (*Z. angew. Chem.*, 1923, 36, 137—138).—Compounds of the types  $MeX_n, 1A$ ;  $MeX_n, 2A$ ;  $MeX_n, 4A$ ;  $MeX_n, 1A$ ;  $MeX_n, 2A$ ;  $MeX_n, 3A$ ;  $MeX_n, 4A$ ; and  $MeX_n, 3A$  such as

and  $CaBr_2, 3NH_2 \cdot CH_2 \cdot CO_2H$  have been prepared in crystalline form and they yield clear neutral aqueous solutions. From a consideration of their solubility, optical activity, and depression of the freezing point in aqueous solution, it is concluded that these complex compounds exist even in solution. Hence it is suggested that the adsorption of salts by the more complex colloids, such as albumin, is partly due to chemical combination, and the fact that such adsorption does not occur in definite constant proportions is ascribed to the inability of the normal salt to penetrate completely into the complex albumin molecules. This chemical theory of adsorption is also considered to hold good in industrial processes such as dyeing, weighting of silk, and tanning. A. J. H.

**Synthesis of Two New Leucines.** K. KURONO (*Biochem. Z.*, 1922, 134, 434—436).— $\alpha$ -Amino- $\alpha$ -methylvaleric acid and  $\alpha$ -amino- $\alpha$ -dimethylpropionic acid have been prepared by the method of Zelinsky and Stadnikoff. The former melts in a sealed tube at 295° and forms a deep blue copper salt, readily soluble in water and in spirit.  $\alpha$ -Naphthylcarbamido- $\alpha$ -methylvaleric acid melts at 191°. The second acid melts in a sealed tube at 293° and forms a deep blue copper salt, easily soluble in water. H. K.

**A New Type of Nitrogenous Sugar Derivative.** JOHN PRYDE (*Rep. Brit. Assoc.*, 1922, 357—358).—Tetramethylglucose was oxidised to tetramethylgluconic acid, which was isolated as the lactone. When this was treated with dry ammonia in alcoholic solution, a crystalline compound was obtained which appeared to

be, not the acid amide, but an amino-lactone. When this was treated with cold alkaline hypochlorite, a crystalline substance was obtained having the composition of the expected intermediate carbimide, but also having, from its behaviour, the constitution of an internal urethane,  $\text{OMe-CH} \begin{smallmatrix} \text{CH(OMe)} \\ \text{CH-O-CO} \end{smallmatrix} \text{>NH}$ . The formation of this substance shows the stabilising effect of methyl groups in the sugar chain and is an interesting example of the conversion of a carbohydrate into a derivative in which nitrogen is present in a stable cyclic substituent.

E. H. R.

**A Remarkable Occurrence of Carbamide.** EDMUND O. VON LIPPMANN (*Ber.*, 1923, 56, [B], 566—567).—A deposit observed in the blind end of a tube connected with the main steam supply of a beet-sugar factory was found to consist of nearly pure carbamide. The ammoniacal liquor of the evaporating plant was used as feed water for the boilers, and was apparently unusually rich in ammonia. Ammonium carbamate appears to have been the precursor of carbamide.

H. W.

**Urethanes from Chlorine-substituted Secondary and Tertiary Alcohols.** LESTER YODER (*J. Amer. Chem. Soc.*, 1923, 45, 475—479).—The carbamates of chlorine-substituted secondary and tertiary alcohols containing a trichloromethyl group were prepared by treating the sodium or the magnesium bromide derivative in benzene or ethereal solution with carbonyl chloride and then adding ammonia to the acid chloride thus formed. In this way were prepared *dimethyltrichloromethylcarbonyl carbamate*, m. p.  $102^{\circ}$ , *phenyltrichloromethylcarbonyl carbamate*, m. p.  $127^{\circ}$ , *dimethyltrichloromethylcarbonyl carbamate*, m. p.  $118^{\circ}$ , *dimethyldichloromethylcarbonyl carbamate*, m. p.  $122^{\circ}$ , and *methyltrichloromethylcarbonyl carbamate*, m. p.  $125^{\circ}$ .

Chloral hydrate condenses with glycerol in the presence of zinc chloride to give *2-trichloromethyl-1:3-dioxolane-4-carbinol*,

b. p.  $125\text{--}128^{\circ}/10\text{ mm.}$ , which yielded a *urethane*, m. p.  $114^{\circ}$ .

The new alkyltrichloromethyl carbamates are tasteless and odourless. Methyl- and dimethyl-trichloromethyl carbamates have quite a strong hypnotic action. The dioxolane has a marked and fleeting hypnotic effect but its urethane has practically no hypnotic effect.

W. G.

**Ethyl Succinamate.** P. P. RUBCOV (*J. Russ. Phys. Chem. Soc.*, 1918, 50, [1—2], 136—137).—*Ethyl succinamate*,

m. p.  $74\text{--}75^{\circ}$ , b. p.  $230\text{--}240^{\circ}$ , is obtained by heating the silver salt of the corresponding acid in a sealed tube for two hours at  $60\text{--}65^{\circ}$  with ethyl iodide.

R. T.

**Decomposition and Formation of Calcium Cyanamide.** VICTOR EHRLICH (*Z. Elektrochem.*, 1922, 28, 529—542).—The con-

ditions under which the decomposition and formation of calcium cyanamide occur have been experimentally investigated. It is shown that the decomposition of calcium cyanamide, which commences above  $1100^{\circ}$ , is not determined solely by the temperature. Above  $1200^{\circ}$ , calcium cyanamide sublimes, but at  $1300^{\circ}$  a re-formation of calcium carbide can be deduced from the separation of lime and carbon in the nitrolime reaction. The carbon monoxide thus produced decomposes the pure sublimed calcium cyanamide partly with the formation of lime and carbon and partly with the formation of calcium carbide. Pure calcium cyanamide sublimes at  $1300^{\circ}$  without previously melting; the addition of approximately 10% of lime reduces the melting point to  $1200^{\circ}$ , and an addition of 15% of calcium chloride reduces it to  $850-900^{\circ}$ . Calcium cyanamide, free from carbon, decomposes above  $1000^{\circ}$  with the liberation of nitrogen according to the equation  $\text{CaC} + \text{N}_2 = \text{CaCN}_2$ . Dissociation pressure measurements have been made for various temperatures; the following values are recorded:  $1000^{\circ}$ , 2.5 mm.,  $1100^{\circ}$ , 14 mm.,  $1140^{\circ}$ , 32 mm., and  $1190^{\circ}$ , 73 mm. The addition of other materials to calcium cyanamide has little effect on the dissociation pressure at temperatures below  $1200^{\circ}$ , but above this temperature, due to the rapid sublimation of the calcium cyanamide and consequent reduction of the concentration, the dissociation pressure is strongly reduced. The decomposition of calcium cyanamide takes place with a much smaller nitrogen pressure than is the case with nitrolime under the same temperature conditions. The presence of carbon, therefore, raises the dissociation pressure, very probably under the influence of the reaction  $\text{CaC}_2 = \text{CaC} + \text{C}$  which takes place from left to right below  $1100^{\circ}$  and in the opposite sense above this temperature. The process is a heterogeneous one, the course of which is determined by the constitution of the surface and the velocity of diffusion. The nitrolime reaction represented by the equation  $\text{CaC}_2 + \text{N}_2 = \text{CaCN}_2 + \text{C}$  can be regarded as made up of the two reactions indicated by equations, above. A primary formation of cyanide is unlikely. The heat change of the formation of calcium cyanamide has been calculated on the basis of the Nernst heat theorem, and the value 61400 cal. obtained. It is likely that the heat change in the formation of nitrolime does not differ much from this value but is possibly a little higher.

J. F. S.

**Action of Organometallic Derivatives of Magnesium on Nitriles.** P. BRUYLANTS (*Bull. Acad. roy. Belg.*, 1922, [v], 8, 7-23).—Acetonitrile (1 mol.) reacts with ethereal magnesium methyl (ethyl) bromide (1 mol.) to give methane (ethane) (1 mol.), and, according to conditions, either diacetonitrile, or one of its condensation products (3-cyano-6-hydroxy-2:4-dimethylpyridine [cf. Moir, T., 1902, 81, 100] or 6-amino-3-cyano-2:4-dimethylpyridine [cf. von Meyer, A., 1908, i, 909]). The initial course of the reaction is to be represented thus:  $\text{CH}_3\text{CN} \rightleftharpoons \text{CH}_2\text{:CNH} \rightarrow \text{CH}_2\text{:CNMgBr} \rightarrow \text{NH:CMg-CH}_2\text{CN}$ . No acetone is formed, and special care is necessary if diacetonitrile itself is required. Two

other substances are formed: (1) a solid substance,  $C_8H_7N_3$  (?), m. p. 198–200°, converted by boiling water into ammonia and a substance of m. p. 135°; and (2) a base,  $C_7H_7N_2$  (?), m. p. 123°, giving a chloroaurate, m. p. 103°.

E. E. T.

**Action of Organometallic Derivatives of Magnesium on Nitriles.** OMER DE BOOSERÉ (*Bull. Soc. chim. Belg.*, 1923, 32, 26–51).—An investigation affording further evidence that nitriles do not always behave normally with the Grignard reagent.  $\gamma$ -Chlorobutyronitrile, when treated with an equimolecular proportion of magnesium ethyl bromide, is converted into four substances, as follows: (1) *cyclopropyl ethyl ketone* (23–25%) (cf. A., 1909, i, 226). (2) *Ethyl  $\gamma$ -chloropropyl ketone* (14–17%), colourless liquid, b. p. 182–183°/761 mm., or 77.5–78.5°/15 mm.,  $n_D^{20}$  1.4411,  $d_4^{20}$  1.0269; gives a *semicarbazone*, m. p. 98–99°; with solid potassium hydroxide gives *cyclopropyl ethyl ketone* (cf. A., 1889, 843), the latter giving the chloro-ketone when treated with hydrochloric acid. This fraction (2) also contains *cyclopropyl ethyl ketimine*, liquid, b. p. 127–128°/759 mm. (*hydrochloride*, solid, b. p. 160–170°/14–16 mm.) (cf. A., 1920, i, 485). (3) *Ethyl amyl ketone* (?). (4) Polymerides of *cyclopropane carboxylonitrile*. When, in the above reaction, two molecular proportions of Grignard reagent are used, the yields of fractions (1) and (2) become, respectively, 28–30% and 27–31%.

The interaction of magnesium ethyl bromide and ethyl  $\gamma$ -chloropropyl ketone affords as primary product the expected *diethyl- $\gamma$ -chloropropylcarbinol*, but the latter on distillation, even under diminished pressure, decomposes to give (1)  $\beta$ -ethylhexylene  $\beta$ -oxide, b. p. 145–150°,  $n_D^{20}$  1.4317,  $d_4^{20}$  0.8703, (2)  $\zeta$ -chloro- $\gamma$ -ethyl- $\Delta^1$ -hexene, b. p. 173°,  $n_D^{20}$  1.4524,  $d_4^{20}$  0.9102, and (3) an inseparable mixture (b. p. 90–105°/15 mm.), probably containing *diethyl- $\gamma$ -chloropropylcarbinol* and  $\gamma$ -*dichloro- $\gamma$ -ethylhexane* (cf. A., 1909, i, 79). The product of the interaction of magnesium ethyl bromide and ethyl  $\gamma$ -chlorobutyrate, evidently the above carbinol, decomposes, even on distillation under diminished pressure, more of the chlorohexene being produced in this case.

$\beta$ -Chlorobutyronitrile (1 mol.) and magnesium ethyl bromide (1 mol.) give rise to a mixture containing (1) the two isomeric crotononitriles (cf. A., 1922, i, 817), (2), the *trimeride* of one of these, white needles, m. p. 173–174°, b. p. 215–240°/13 mm., and (3) a small quantity of a mixture of two ketones. When 2 mols. of Grignard reagent are used, the main product is the trimeric crotononitrile.

$\alpha$ -Chlorobutyryl chloride, when added to aqueous ammonia at 0°, is converted into  $\alpha$ -chlorobutyramide, which also is formed when methyl  $\alpha$ -chlorobutyrate is digested for several hours with concentrated aqueous ammonia. The author notes that the chlorination of a mixture of butyric acid and butyryl chloride gives, besides  $\alpha$ -chlorobutyryl chloride, the *anhydride*, b. p. 125–130°/15 mm.

$\alpha$ -Chlorobutyramide, white needles, m. p. 81°, gives  $\alpha$ -chlorobutyronitrile with thionyl chloride. This nitrile, with one mole-

cular proportion of magnesium ethyl bromide, is converted into a mixture containing (1) a small quantity of an unsaturated hydrocarbon (?), b. p. 76–85°, (2) the two crotononitriles, and (3) unidentified products of higher b. p. When two molecular proportions of Grignard reagent are used, no hydrocarbon is formed and very little crotononitrile, the main product being an amine, which the author believes to be  $\gamma$ -imino- $\gamma$ -ethylhexane,  $\begin{matrix} \text{C} \\ \text{C} \end{matrix} \begin{matrix} \text{Et}_2 \\ \text{Et} \end{matrix} > \text{NH}$ .

The latter boils at 157–158°, combines with calcium chloride, forms a hydrochloride (white needles, m. p. 185–186°), gives a yellow crystalline chloroplatinate and reacts with bromine to give a *N*-bromo-derivative. A secondary product of the above reaction, of unknown constitution, boils at 118–123°/15 mm. E. E. T.

**Solubility of Prussian Blue.** MORTZ KOHN (*Monatsh.*, 1923, 43, 373–376).—Prussian Blue dissolves in solutions of the neutral oxalates of potassium, sodium, and ammonium to give greenish solutions. The interaction of ferric chloride and potassium ferrocyanide, even if an excess of one of these substances is present, does not lead to a precipitate of Prussian blue in presence of these neutral oxalates. The above green solutions, unlike those of Prussian blue in aqueous oxalic acid, are true solutions.

E. E. T.

**The Formation of Hydroxamic Acids from Keten.** CHARLES DE WITT HURD and PAUL B. COCHRAN (*J. Amer. Chem. Soc.*, 1923, 45, 515–521).—Keten will react readily with a monohydroxamic acid to form, not only a monoacetyl ester, but also a diacetyl ester. In this way, from pyromucylhydroxamic acid the authors obtained, not only the monoacetate, m. p. 94–96°, but also the diacetate, m. p. 54–55°. Similar results were obtained with diphenylacet-hydroxamic acid and benzhydroxamic acid.

An improved apparatus is described for preparing keten by the method of Schmidlin and Bergman (*A.*, 1910, i, 816), the undecomposed acetone issuing from the reaction tube being removed from contact with the keten almost as soon as it leaves the tube.

The similarity of the behaviour of keten and of phenylthiocarbimide towards monohydroxamic acids is discussed. W. G.

**Mercury Propyl and Mercury isoPropyl.** MARCEL GORET (*Bull. Sci. Pharmacol.*, 1922, 29, 297–305; from *Chem. Zentr.*, 1922, iii, 1371).—Mercury dipropyl is prepared by the action of sodium amalgam on propyl bromide in the presence of ethyl acetate. It is separated from the products of reaction by distillation in steam and subsequent fractionation; it has  $d_4^{20}$  2.046; b. p. 189°/760 mm., 82–86°/25 mm. From the residue after steam distillation mercury propyl is obtained after crystallisation from ethyl alcohol in leaflets, m. p. 135°. Mercury propyl chloride is obtained by the action of mercuric chloride on mercury propyl in alcoholic solutions; it forms white scales, m. p. 143°. Mercury propyl bromide, from the action of bromine on mercury propyl, forms leaflets, m. p. 135°. Mercury propyl iodide is crystalline, m. p. 113°. Mercury propyl acetate, from the action of acetic anhydride on mercury dipropyl or of

acetic acid on the corresponding hydroxide, is crystalline, m. p. 57–58°. *Mercury diisopropyl* has b. p. 75–77°/25 mm.,  $d_4^{20}$  2.05. *Mercury isopropyl hydroxide* is prepared by the action of moist silver oxide on one of the halides. It gives with the corresponding acids, *mercury isopropyl sulphide*, m. p. 60°; *mercury isopropyl cyanide*, m. p. 85°; *mercury isopropyl acetate*, m. p. 95°; *mercury isopropyl chloride*, needles, m. p. 97°. *Mercury isopropyl bromide* forms needles, m. p. 98°; *mercury isopropyl iodide*, leaflets, m. p. 125°.

G. W. R.

**Low Temperature Coal Tar and the Products of its Superheating.** FRANZ FISCHER (*Ber.*, 1923, 56, [B], 601–603).—In a recent communication, Schütz (this vol., i, 195) has described a low temperature tar which differs greatly from that obtained previously by the author and his co-workers (*A.*, 1917, i, 258; 1920, i, 277), in that it contains very considerable amounts of benzene and phenol. The differences cannot be attributed solely to the differing types of coal employed; it appears that the product examined by Schütz was a superheated low-temperature tar. The temperature employed (500–600°) is considerably higher than that which is actually necessary, and the structure of Schütz's retorts is such that the volatile products are necessarily exposed to the highest temperature of the furnace. Under these conditions, it has been shown previously that hydroaromatic hydrocarbons are dehydrogenated to benzene, and phenols with a long side chain are transformed into phenol and olefinic hydrocarbons. The volume of gas obtained by Schütz from each ton of coal is much greater than that usually observed in low-temperature work, and affords additional evidence of secondary decomposition. H. W.

**The Benzene Theory.** C. W. A. LELY (*Chem. Weekblad*, 1923, 20, 82–83).—An answer to criticisms by Olivier, by Prins, and by Schoutissen (this vol., i, 195, 196) of the triangular formula suggested by the author (this vol., i, 99).

S. I. L.

**Is Kekulé's Benzene Theory Tenable?** C. W. A. LELY (*Chem. Weekblad*, 1923, 20, 90–96).—The triangular formula and the theory of synchronous rotation put forward for benzene (this vol., i, 99) are developed and extended to pyridine, thiophene, pyrrole, quinoline, pyrazole, glyoxaline, etc.

S. I. L.

**Solubility of cyclohexane in Liquid Sulphur Dioxide.** W. F. SEYER and V. DUNBAR (*Trans. Roy. Soc. Canada*, 1922, 16, III, 307–310).—A determination of the equilibrium diagram of the system liquid sulphur dioxide–cyclohexane indicates the existence of a transition point at  $-17.0^\circ$ , corresponding with the maximum solubility of sulphur dioxide in cyclohexane, and of a eutectic point at  $-72.5^\circ$ , at which temperature the solubility of cyclohexane in liquid sulphur dioxide is very small. Above  $13.6^\circ$ , the liquids are miscible in all proportions. No evidence of the formation of compounds of the two substances, as suggested by Moore, Morrell, and Egloff (*A.*, 1918, i, 285), was obtained.

J. S. G. T.

**Trifluoromethylcyclohexane.** FRÉD. SWARTS (*Bull. Acad. roy. Belg.*, 1922, [v], 8, 505—530; *Bull. Soc. chim. Belg.*, 1923, 32, 70—79).—A continuation of previous work (A., 1921, i, 656). The m. p. of trifluoromethylcyclohexane is  $-103.4^{\circ}$  to  $-103.5^{\circ}$ . The group  $\cdot\text{CF}_3$  is even more resistant to reagents in this case than in the case of benzotrifluoride. Trifluoromethylcyclohexane is hydrolysed to cyclohexanecarboxylic acid only to the extent of 3% when heated at  $180^{\circ}$  with aqueous hydrobromic acid ( $d^{17} 1.768$ ) for eighty hours, in presence of silicon dioxide. Neither sodium hydroxide nor sodium amalgam affects the fluoro-compound in alcoholic solution. Bromine (1 mol.), at  $130^{\circ}$  under pressure, affords the bromo-derivative, a colourless liquid, b. p.  $177-178^{\circ}$ ,  $d^{16} 1.561$ , together with the dibromo-derivative (the main product), b. p.  $218-220^{\circ}$  (slight decomp.), or  $120-122^{\circ}/30$  mm.,  $d^{17} 1.912$ , and a little tribromo-derivative, b. p.  $260-265^{\circ}$  (slight decomp.). The introduction of a bromine atom into the cyclohexane ring in this case facilitates further substitution. An excess of bromine (under pressure, at  $170^{\circ}$ ) converts the original fluoro-compound into a mixture of 3:4- and 2:5-dibromobenzoic acids and another substance not identified. Dilute permanganate solutions have little effect on the fluoro-compound at water-bath temperatures; no toluene derivatives are formed, the change that does occur resulting in complete oxidation of the molecule.

In an attempt to prepare the hexanol from trifluoromethylbromocyclohexane, the latter was heated under pressure with an aqueous suspension of mercuric oxide, and gave rise, instead, to trifluoromethylcyclohexene, a mobile liquid, b. p.  $104.5-105.5^{\circ}$ ,  $d^{16} 1.127$ ; dibromide (?), b. p.  $219-220^{\circ}$ .

Zinc and ethyl alcohol converted trifluoromethyldibromocyclohexane into what is probably the same hexene. The product boils at  $104.7-104.9^{\circ}/762$  mm., and has  $d^{16} 1.1368$  and  $d^{18} 1.1194$ . It forms a constant boiling mixture with alcohol (b. p.  $74.4^{\circ}$ ; 57.5% of the hexene).

In the dibromo-derivative, one bromine atom is in position 3 ( $\cdot\text{CF}_3$  in 1), and the other in position 2 or 4.

Nitric acid ( $d 1.15$ ) at  $130^{\circ}$  converts trifluoromethylcyclohexane into a mononitro-derivative, but a large amount of decomposition occurs (see below). The nitro-derivative is a viscous liquid, b. p.  $224-225^{\circ}$  or  $124.5^{\circ}/30$  mm.,  $d^{16} 1.3154$ . The sodium derivative is very soluble in alcohol. Among the products of decomposition referred to were isolated trifluoroacetic, succinic, and trifluoromethyladipic acids (?); other products probably were fluoro-derivatives of  $\text{C}_6$  and  $\text{C}_7$  carboxylic acids. Similar decomposition products were obtained by heating the nitrocyclohexane with nitric acid.

E. E. T.

**The Isomeric Trinitrotoluenes.** H. BRUNSWIG (*Z. anorg. Chem.*, 1923, 36, 75—76).—A short review of the work to date on the preparation of the six isomeric trinitrotoluenes. The results of an investigation on the stability of these compounds towards heat, either alone or mixed with one-fifth of their weight of sodium

hydroxide, and on their behaviour towards sodium carbonate and lead oxide in boiling alcohol are given in tabular form with a view to supply a method for their identification, and also for their detection in the manufactured product. Their detonation temperatures, when heated alone, are all in the neighbourhood of  $100^{\circ}$  and are too close to one another to be of service. The remaining tests applied resulted as follows— $\alpha$ -Trinitrotoluene [2:4:6] (a) m. p.  $80.5^{\circ}$ . (b) Crystallises from methyl alcohol in needles. (c) With sodium carbonate in boiling alcohol, coloured dark reddish-brown without transformation into dinitrocresol; on continued boiling is converted into another dark salt. (d) With lead oxide in boiling alcohol, unaltered. (e) Detonation temperature mixed with sodium hydroxide,  $230-233^{\circ}$ .  $\beta$ -Trinitrotoluene [2:3:4] (a) m. p.  $112^{\circ}$ . (b) Needles. (c) Forms sodium dinitrotolyloxide readily. (d) Gives the readily detonated lead dinitrotolyloxide. (e)  $208-215^{\circ}$ .  $\gamma$ -Trinitrotoluene [3:4:6] (a) m. p.  $104^{\circ}$ . (b) Granulates. (c) and (d) As with  $\beta$ -compound. (e)  $193-198^{\circ}$ .  $\delta$ -Trinitrotoluene [3:4:5] (a) m. p.  $137.5$  ( $134^{\circ}$ ). (b), (c), and (d) As with  $\gamma$ -compound. (e)  $252^{\circ}$ .  $\epsilon$ -Trinitrotoluene [2:3:6] (a) m. p.  $111^{\circ}$ . (b) Needles. (c) Some sodium dinitrotolyloxide very slowly formed. (d) Almost unattacked. (e)  $249-250^{\circ}$ .  $\zeta$ -Trinitrotoluene [2:3:5] (a)  $97^{\circ}$ . (b) Granulates. (c) and (d) As with  $\beta$ -compound. (e)  $268-271^{\circ}$ . T. S. W.

#### Solubility of 2:4:6-Trinitrotoluene in Organic Solvents.

J. A. TAYLOR and WM. H. RINKENBACH (*J. Amer. Chem. Soc.*, 1923, 45, 44-59).—The solubility of 2:4:6-trinitrotoluene has been determined at a series of temperatures in water, aniline, pyridine, toluene, acetone, benzene, carbon tetrachloride, 95% ethyl alcohol, chloroform, carbon disulphide, and diethyl ether. An equimolecular compound is formed in pyridine solution which exists at temperatures below  $40^{\circ}$  and melts at  $40-42^{\circ}$ . The following data are recorded, in grams per 100 g. of solvent: water,  $3^{\circ}$ , 0.0110;  $5.9^{\circ}$ , 0.0113;  $20.0^{\circ}$ , 0.0120;  $33.1^{\circ}$ , 0.0203;  $44.2^{\circ}$ , 0.0340;  $45^{\circ}$ , 0.0370;  $53.0^{\circ}$ , 0.0534;  $57.15^{\circ}$ , 0.0614;  $73.25^{\circ}$ , 0.0963;  $84.4^{\circ}$ , 0.1375, and  $99.5^{\circ}$ , 0.1467; ether,  $0.3^{\circ}$ , 1.75;  $5.9^{\circ}$ , 2.13;  $20.3^{\circ}$ , 3.33;  $26.0^{\circ}$ , 3.92, and  $33.0^{\circ}$ , 5.15; 95% alcohol,  $0.3^{\circ}$ , 0.70;  $32.0^{\circ}$ , 1.99;  $40.1^{\circ}$ , 2.98;  $45.0^{\circ}$ , 3.70;  $50.0^{\circ}$ , 4.61;  $55.0^{\circ}$ , 6.08;  $59.8^{\circ}$ , 8.14;  $65.0^{\circ}$ , 11.40, and  $74.0^{\circ}$ , 18.58; carbon disulphide,  $0.3^{\circ}$ , 0.158;  $5.6^{\circ}$ , 0.20;  $11.1^{\circ}$ , 0.27;  $24.5^{\circ}$ , 0.62;  $30.1^{\circ}$ , 0.84;  $35.0^{\circ}$ , 1.12;  $40.0^{\circ}$ , 1.53;  $45.0^{\circ}$ , 2.02, and  $46.3^{\circ}$ , 2.20; carbon tetrachloride,  $0.3^{\circ}$ , 0.22;  $5.6^{\circ}$ , 0.28;  $11.1^{\circ}$ , 0.37;  $24.5^{\circ}$ , 0.76;  $35.0^{\circ}$ , 1.32;  $45.0^{\circ}$ , 2.37;  $57.0^{\circ}$ , 5.33;  $61.7^{\circ}$ , 8.14;  $67.0^{\circ}$ , 13.68;  $72.5^{\circ}$ , 20.72, and  $78.2^{\circ}$ , 29.76; chloroform,  $0.3^{\circ}$ , 6.33;  $32.0^{\circ}$ , 37.7;  $40.1^{\circ}$ , 66.6;  $50.0^{\circ}$ , 101;  $50.0^{\circ}$ , 150;  $55^{\circ}$ , 218;  $59.8^{\circ}$ , 296, and  $65.0^{\circ}$ , 442. The other solvents mentioned above dissolve very large quantities of trinitrotoluene, and in these cases the solubility was determined by the cooling-curve method. The whole of the values are recalculated to grams per 100 g. of solvent and tabulated, giving the solubility for temperatures in  $5^{\circ}$  intervals over the whole range examined.

J. F. S.

**Preparation of Salts of 1 : 3-Dinitro-4 : 5-dinitrosobenzene.** HANS RATHSBURG (Brit. Pat. 190844).—Sparingly soluble salts of 1 : 3-dinitro-4 : 5-dinitrosobenzene are obtained by heating picryl chloride (25 kg.) in aqueous suspension with a solution of sodium azide (7 kg.) in 300 litres of water for one hour at 80–90°, and for three hours at 90–100°, whereby the picryl azide first formed is transformed with loss of nitrogen into 1 : 3-dinitro-4 : 5-dinitrosobenzene, which is separated from the mother-liquors, converted into its sodium salt by treatment with sodium hydroxide, and then in the moist state is allowed to react with the acetate or chloride of the metal of which the dinitrodinitrosobenzene salt is required.

G. F. M.

**Sulphinic Acids.** JULIUS VON BRAUN and WILHELM KAISER (Ber., 1923, 56, [B], 549–553).—The action of aromatic sulphonyl chlorides on dithiocarbamates takes place unexpectedly in accordance with the scheme  $2\text{NR}_2 \cdot \text{CS} \cdot \text{SH} \cdot \text{NHR}_2 + \text{Cl} \cdot \text{SO}_2 \cdot \text{R}^1 = \text{NR}_2 \cdot \text{CS} \cdot \text{S} \cdot \text{CS} \cdot \text{NR}_2 + \text{NHR}_2 \cdot \text{HCl} + \text{SO}_2 \cdot \text{H} \cdot \text{R}^1 \cdot \text{NHR}_2$ , and thus affords a ready method of preparing sulphinic acids. The conversion of the latter into amides has not been effected previously (Knoevenagel and Polak, A., 1908, i, 971; Hilditch and Smith, A., 1909, i, 18). It is now shown that the transformation occurs normally in the presence of an indifferent solvent, but that the new amides are much more readily decomposed than the analogous carboxylamides; they are unable to yield derivatives of the amide-chloride and imide-chloride types.

Dimethylamine, carbon disulphide, and benzenesulphonyl chloride give tetramethylthiuram disulphide, m. p. 150–154°, (?) benzenesulphondimethylamide, and benzenesulphinic acid, m. p. 83°, which is conveniently isolated through its ferric salt (cf. Thomas, T., 1909, 95, 342). Piperidine, carbon disulphide, and benzenesulphonyl chloride give dipiperidylthiuram disulphide, m. p. 128°, and benzenesulphinic acid. *p*-Toluenesulphinic acid, m. p. 84°, is prepared from piperidine, carbon disulphide, and *p*-toluenesulphonyl chloride, whilst tetrahydronaphthalene- $\beta$ -sulphonyl chloride gives dipiperidylthiuram disulphide, tetrahydronaphthalene- $\beta$ -sulphonylpiperidine,  $\text{C}_{10}\text{H}_7 \cdot \text{SO}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{NH}_{10}$ , m. p. 98–100°, and tetrahydronaphthalene- $\beta$ -sulphinic acid, colourless needles, m. p. 87–88°.

Benzenesulphinanilide,  $\text{SOPh} \cdot \text{NHPh}$ , m. p. 112–114°, is prepared by the action of benzenesulphonyl chloride on two molecular proportions of aniline dissolved in ether at 0°. It is extensively decomposed by boiling acids without appearing to undergo a smooth fission into benzenesulphinic acid and aniline, which can, however, be brought about by cold, aqueous-alcoholic alkali hydroxide solutions. Benzenesulphinpiperidine has m. p. 83° after softening at 80°; it is energetically attacked by phosphorus pentachloride even in the presence of chloroform, and gives chlorinated compounds, the reaction appearing to occur in a direction different from that of benzoylpiperidine. Benzenesulphindimethylamide,  $\text{SOPh} \cdot \text{NMe}_2$ , is a yellow liquid, b. p. 90°/2–3 mm. Benzenesulphinamide has m. p. 121°. Toluene-*p*-sulphonyl chloride, b. p.

115—120°/4 mm., is converted in a similar manner into the corresponding *anilide*, m. p. 138°, and *amide*, colourless needles, m. p. 120° after softening at 117°.

H. W.

**Alkylamides of Aromatic Sulphonic Acids.** W. BADER and D. A. NIGHTENGALE (U.S. Pat. 1433925).—When xylenesulphonyl chloride and methylamine hydrochloride are heated with sodium carbonate at 80—100° in presence of moisture not exceeding 5%, xylenesulphonmethylamide is produced and may be recovered by extraction with benzene. The instance quoted is an example of a reaction of more general application. Benzene or other diluents may be present.

CHEMICAL ABSTRACTS.

**Preparation of Aromatic Sulphones.** G. FOUQUE and J. LACROIX (*Bull. Soc. chim.*, 1923, [iv], 33, 180—183).—By the prolonged action of sulphuric acid on aromatic hydrocarbons or their derivatives under such conditions that the water formed during the reaction and condensing in the reflux condenser is not allowed to run back into the reaction mixture, aromatic sulphones were obtained in good yield. Their formation may be due to the action of a further quantity of hydrocarbon on the sulphonic acid produced, as, for example, with benzene,  $\text{PhSO}_3\text{H} + \text{C}_6\text{H}_6 = \text{SO}_2\text{Ph}_2 + \text{H}_2\text{O}$ , or more probably by reason of the decomposition of the sulphonic acid under the influence of heat and in the absence of water, thus:  $2\text{PhSO}_3\text{H} = \text{SO}_2\text{Ph}_2 + \text{H}_2\text{SO}_4$ . The conditions required for the reaction were obtained by interposing between the reflux condenser and the reaction vessel a flask with a side tubulure in the bulb, a tube bent at right angles passing through this tubulure and connecting with the neck of the reaction flask. By this means the water and the hydrocarbon condensing in the reflux condenser flow back into the tubulated flask and separate into two layers, and consequently only the lighter hydrocarbon flows back through the tubulure into the reaction flask. When the substance to be sulphonated is heavier than water, the connecting tube is bent downwards to the bottom of the tubulated flask, so that the lower layer passes back into the reaction flask instead of the upper aqueous layer; a small orifice on the upper side of the tube just before the bend serves for the passage of the vapours from the reaction flask. By means of this apparatus diphenylsulphone, m. p. 128°, *di-p-chlorodiphenylsulphone*, m. p. 146°, *di-p-bromodiphenylsulphone*, m. p. 171°, and *di-p-hydroxydiphenylsulphone*, m. p. 240°, were prepared.

G. F. M.

**Doubly Refractive Naphthalene.** W. KIRBY (*J. Soc. Chem. Ind.*, 1923, 42, 58T).—When naphthalene, m. p. 80·7°,  $d_4^{20}$  1·185, is melted in a suitable vessel and allowed to cool, the substance in contact with the sides of the vessel solidifies to form a clear, transparent mass which is doubly refractive; the resolving power is more than 30% greater than that of Iceland spar.

W. P. S.

**Some Fluoro-derivatives of Diphenyl.** THÉO VAN HOVE (*Bull. Acad. roy. Belg.*, 1922, [v], 8, 505—530; *Bull. Soc. chim. Belg.*, 1923, 32, 52—70).—Diphenyl (500 g.) is nitrated in the cold

with an acetic acid solution containing 2 mols. of nitric acid (*d* 1.5). After a time, most of the 4-nitrodiphenyl separates, and from the mother-liquor, by precipitation with water, etc., and distillation under diminished pressure, 2-nitrodiphenyl (195 g.) is obtained, b. p. 200—205°/30 mm., together with more 4-nitrodiphenyl (350 g. in all).

In the reduction of 4-nitrodiphenyl by means of tin and hydrochloric acid, the sparingly soluble chlorostannate is best separated by filtration. 4-Aminodiphenyl boils at 210—212°/25 mm. 2-Aminodiphenyl forms a soluble chlorostannate, and boils at 189—191°/30 mm.

4-Fluorodiphenyl, obtained by diazotising 4-aminodiphenyl in hydrofluoric acid solution, and subsequently heating at 60°, forms colourless plates, m. p. 74.2°, b. p. 253°, and is volatile in steam. 2-Fluorodiphenyl, obtained similarly, colourless prisms, m. p. 73.5°, b. p. 248°, is also volatile in steam.

The nitration of 4-fluorodiphenyl in acetic acid solution, using nitric acid (*d* 1.5), gave three products: (a) 4-fluoro-4'-nitrodiphenyl, needles, m. p. 123°, giving *p*-nitrobenzoic acid on oxidation; (b) an approximately equal weight of 4-fluoro-2'-nitrodiphenyl, needles, m. p. 59—60°, giving, on oxidation, *p*-fluorobenzoic acid, and (c) a very small quantity of 4-fluoro-2-nitrodiphenyl, prisms, m. p. 53—54°, giving, on oxidation, 4-fluoro-2-nitrobenzoic acid, m. p. 130°. In the first experiment, but never subsequently, the author obtained pale yellow prisms, m. p. 43—43.5°, which, on keeping, became opaque, and then melted at 58°. This is apparently a case of dimorphism.

4-Fluoro-4'-aminodiphenyl, obtained by the reduction of the corresponding nitro-compound, forms colourless leaflets, m. p. 120°; hydrochloride, sparingly soluble leaflets; sulphate and oxalate, very sparingly soluble leaflets; acetyl derivative, m. p. 205—205.5°.

4-Fluoro-2'-aminodiphenyl, colourless crystals, m. p. 42—42.5°, b. p. 186—187°/40 mm., forms a hydrochloride, m. p. about 210°, and a sulphate, which are much more soluble than the corresponding salts of the 4'-derivative. The amine, on oxidation, gives *p*-fluorobenzoic acid and yields an acetyl derivative, m. p. 120°.

4-Fluoro-2-nitrodiphenyl, on reduction, gives an amine, the acetyl derivative of which melts at 98°.

2-Fluorodiphenyl gives rise to three isomeric nitro-derivatives: (a) a small quantity of colourless needles, m. p. 81°, probably 2-fluoro-4-nitrodiphenyl, since the acetyl derivative (colourless prisms, m. p. 155°) of the amine obtained by reduction gives, on oxidation, benzoic acid, (b) 2-fluoro-4'-nitrodiphenyl, yellow needles, m. p. 74.5°, giving, on oxidation, *p*-nitrobenzoic acid, and (c) 2-fluoro-2'-nitrodiphenyl, prisms, m. p. 71.5°, giving *o*-nitrobenzoic acid on oxidation.

2-Fluoro-2'-aminodiphenyl, colourless crystals, m. p. 91°, gives a very soluble hydrochloride, m. p. about 205°, a soluble sulphate, and an acetyl derivative, colourless needles, m. p. 102°. 2-Fluoro-4'-aminodiphenyl, m. p. 36°, b. p. 199—201°/25 mm., gives a sparingly soluble hydrochloride, m. p. above 250°, a sparingly soluble sulphate, and an acetyl derivative, m. p. 147—148°.

In the nitration of diphenyl, small quantities of a yellow, crystalline solid, m. p.  $202^{\circ}$ , probably 3 : 5 : 4'-trinitro-4-hydroxydiphenyl, are formed. 4-Fluorodiphenyl, similarly, gives rise to a small quantity of a solid,  $C_{12}H_7O_3N_3F$  (?), probably a fluorodinitro-hydroxydiphenyl.

**The Products of the Bromination of *as*-Diphenylethylene.**  
P. LIPP (*Ber.*, 1923, 56, [B], 567—571).—The author's experiences in the bromination of camphene has led him to examine the behaviour of other asymmetrically substituted ethylenes, and for this purpose *as*-diphenylethylene,  $CPh_2:CH_2$ , has been selected. Under certain conditions, the normal dibromide can be isolated, but it passes somewhat readily into diphenylvinyl bromide. Under drastic treatment, the latter substance suffers rearrangement of the diphenylvinyl residue, whereas under milder conditions the radicle remains intact.

[In part with W. LÜDICKE].— $\alpha\beta$ -Dibromo- $\alpha\alpha$ -diphenylethane,  $CPh_2Br:CH_2Br$ , is obtained by the gradual addition of a solution of dry bromine in carbon disulphide to *as*-diphenylethylene dissolved in the same medium at a temperature not exceeding  $0^{\circ}$  and subsequent removal of the solvent in a vacuum at the atmospheric temperature; it crystallises in coarse plates or prisms, decomp.  $63$ — $64^{\circ}$  (corr.). When pure, it may be preserved unchanged for weeks, but rapidly passes when heated into diphenylvinyl bromide, m. p.  $41$ — $42^{\circ}$ . It is converted by methyl-alcoholic potassium hydroxide solution into  $\beta$ -bromo- $\alpha$ -methoxy- $\alpha\alpha$ -diphenylethane,  $OMe:CPh_2:CH_2Br$ , short prisms or plates, m. p.  $73$ — $74.5^{\circ}$  (corr.), which is unaffected by boiling dimethylaniline or aqueous potassium hydroxide solution; molten potassium hydroxide converts it into toluene,  $CPh:CPh$ .  $\beta$ -Bromo- $\alpha$ -ethoxy- $\alpha\alpha$ -diphenylethane crystallises in long prisms, m. p.  $98$ — $99^{\circ}$  (corr.).

Diphenylvinyl bromide is transformed by molten potassium hydroxide into toluene, b. p.  $158$ — $160^{\circ}/10.5$  mm., m. p.  $60^{\circ}$  (corr.) [dibromide, m. p.  $211^{\circ}$  (corr.)]. It reacts with activated magnesium in the presence of ether, and the product after treatment with carbon dioxide yields  $\beta\beta$ -diphenylacrylic acid,  $CPh_2:CH:CO_2H$ , m. p.  $162^{\circ}$  (the sodium salt is relatively sparingly soluble in water), and  $\alpha\alpha\beta\beta$ -tetraphenyl- $\Delta^4$ -butadiene, colourless, thin prisms, m. p.  $205$ — $206^{\circ}$  (corr.).

**Crystalline Form of 4-Chloro-2-bromo-3-nitroacetanilide.**  
MARIA DE ANGELIS (*Atti R. Accad. Lincei*, 1922, [v], 31, ii, 450—453, 524—529; cf. A., 1920, i, 608, 834).—This compound is dimorphous. The metastable  $\alpha$ -modification,  $d$  1.857, forms crystals belonging to the prismatic class of the monoclinic system,  $a:b:c=1.2985:1:0.5728$ ,  $\beta=86^{\circ}43'$ . The stable  $\beta$ -modification,  $d$  1.891, was not obtained in crystals capable of being measured accurately, but appears to be isomorphous with 2:4-dibromo-3-nitroacetanilide (A., 1920, i, 834).

A mixture of 4-chloro-2-bromo-3-nitroacetanilide (1 mol.) with the dibromo-analogue (1 mol.) yields triclinic crystals isomorphous with those of the dibromo-compound (*loc. cit.*, 834). A similar

mixture of 4-chloro-2-bromo-3-nitroacetanilide with the dichloro-compound yields tabular, monoclinic crystals isomorphous with the  $\beta$ -form of the dichloro-derivative (*loc. cit.*, 608), or, less readily, metastable, prismatic crystals of the monoclinic system, isomorphous with those of the metastable modification of 4-chloro-2-bromo-3-nitroacetanilide. T. H. P.

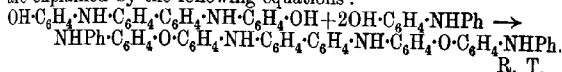

**Solubility of Trinitrophenylmethylnitroamine (Tetryl) in Organic Solvents.** C. Å. TAYLOR and WM. H. RINKENBACH (*J. Amer. Chem. Soc.*, 1923, 45, 104—107).—The solubility of tetryl has been determined in water, ether, 95% alcohol, carbon disulphide, chloroform, and carbon tetrachloride at a large number of temperatures. The following solubilities in grams of tetryl per hundred grams of solvent are recorded: Water, 0.5°, 0.0051; 9.6°, 0.0069; 14.8°, 0.0071; 20.5°, 0.0074; 30°, 0.0084; 35°, 0.0094; 40°, 0.0107; 45°, 0.0135; 50.0°, 0.0200; 60.05°, 0.0350; 65.05°, 0.0443; 69.5°, 0.0531; 84.2°, 0.0952; 96.7°, 0.1619, and 98.55°, 0.1755; ether, 0.4°, 0.1918; 9.6°, 0.3174; 20.5°, 0.4219; 29.05°, 0.4680, and 30.0°, 0.4713; 95% alcohol, 0.5°, 0.324; 25.0°, 0.648; 33.0°, 0.843; 39.0°, 1.08; 45.1°, 1.39; 51.0°, 1.81; 61.0°, 2.76; 70.05°, 4.23, and 77.1°, 5.80; carbon disulphide, 0.4°, 0.0094; 15.0°, 0.0177; 28.0°, 0.0277; 37°, 0.0437; 40°, 0.0557, and 46.1°, 0.1048; chloroform, 0.4°, 0.282; 15°, 0.473; 28.0°, 0.740; 32.2°, 0.856; 40.0°, 1.209; 50.0°, 1.780, and 58.8°, 2.53; carbon tetrachloride, 0.4°, 0.0073; 25.0°, 0.0304; 33.0°, 0.0449; 39.0°, 0.0566; 45.1°, 0.0733; 51.0°, 0.0997; 61.0°, 0.1597; 70.05°, 0.2419, and 73.25°, 0.2773. A table is drawn up giving the interpolated values for every 5° for each solvent over the range investigated. J. F. S.

**Chloroacetyl-*p*-anisidine and its Nitro-derivatives.** FRÉ. DÉRIC REVERDIN (*Helv. Chim. Acta*, 1923, 6, 87—93).—Chloroacetyl-*p*-anisidine is much more resistant to hydrolysis by acids than the corresponding acetyl, benzoyl, and toluenesulphonyl compounds. It has also to be nitrated under conditions unlike those which give the best results in the case of other acyl-derivatives of *p*-anisidine. The mono-nitro-derivative was obtained by dissolving the chloroacetyl-*p*-anisidine (12 g.) in glacial acetic acid (120 c.c.) and running in the nitric acid gradually at 10° (15 c.c., *d* 1.52). The principal product, 3-nitrochloroacetyl-*p*-anisidine, yield 80—82% of theory, forms yellow needles, *m. p.* 104°. A small amount of 2-nitrochloroacetyl-*p*-anisidine, yellow needles, *m. p.* 153°, was also obtained. Like the parent substance, the nitro-derivatives are unusually resistant to acid hydrolysis, but are rapidly hydrolysed to nitroanisidine by 4% potassium hydroxide solution. 2:3-Dinitrochloroacetyl-*p*-anisidine was obtained by nitrating 3-nitrochloroacetyl-*p*-anisidine with nitric acid, *d* 1.52, at the ordinary temperature, finishing at 45°; it forms white, prismatic needles, *m. p.* 172°. A small amount of 2:5-dinitrochloroacetyl-*p*-anisidine was formed at the same time, yellow needles, *m. p.* 128°. 2:3:5-Trinitrochloroacetyl-*p*-anisidine could only be obtained by nitrating the dinitro-compound with mixed

nitric and concentrated sulphuric acids, and the best yield obtained was only 40% of theory. It forms white needles, m. p. 245—246°. The nitro-compounds do not appear to form additive compounds with bases. With aniline, however, 3-nitrochloroacetyl-*p*-anisidine forms a compound which appears to be 3-nitroanilino-acetyl-*p*-anisidine,  $\text{OMe}\cdot\text{C}_6\text{H}_4(\text{NO}_2)\cdot\text{NH}\cdot\text{CO}\cdot\text{CH}_2\cdot\text{NHPh}$ , yellow spangles, m. p. 143°. 2:3-Dinitrochloroacetyl-*p*-anisidine forms with aniline a compound, orange needles, m. p. 153°, containing no chlorine; the trinitro-derivative gives a similar compound, m. p. 172—173°.

E. H. R.

**The Products of the Oxidation of Diphenylamine with Hydrogen Peroxide.** P. P. ROUBCOV (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 137—139).—Uschakov (A., 1906, i, 159; 1907, i, 361) isolated two substances,  $\text{C}_{22}\text{H}_{20}\text{O}_2\text{N}_2$ , and  $\text{C}_{60}\text{H}_{40}\text{O}_2\text{N}_2$ , from the products of the oxidation of diphenylamine with hydrogen peroxide. The first of these he showed to have the structure  $\text{OH}\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{C}_6\text{H}_4\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{OH}$ , and to be formed by the condensation of two molecules of hydroxydiphenylamine. The structure of the second was not determined. It is now suggested that its empirical formula should be  $\text{C}_{48}\text{H}_{36}\text{O}_2\text{N}_4$ , and that the presence of traces of diphenylamine (about 0.15%) could have caused the discrepancy in analysis. Its formation and structure are explained by the following equations:

R. T.

**Action of the Oxides and the Oxy-acids of Nitrogen on Diphenylurethane.** HUGH RYAN and ANNE DONNELLAN (*Proc. Roy. Dublin Soc.*, 1923, 17, 113—118).—It has already been shown (A., 1919, i, 481, 482) that diphenylnitrosoamine can be nitrated more readily than diphenylamine; this is ascribed to the protective influence of the nitroso-group. The nitration of diphenylurethane has now been systematically investigated (cf. Hager, A., 1886, 59).

Nitric acid at the ordinary temperature and at low concentrations in acetic acid solution has apparently no action; under similar conditions in carbon tetrachloride solution, 4:4'-dinitrodiphenylurethane, 2:4'-dinitrodiphenylurethane (cf. Hager, *loc. cit.*), and 4-nitrodiphenylurethane, colourless prisms, m. p. 68°, are formed. Cold concentrated nitric acid (*d* 1.42) converts the urethane into its 4-nitro-derivative, whilst cold fuming nitric acid gives the 4:4'- and the 2:4'-dinitro-derivatives. Diphenylurethane, or its 4-nitro-derivative, is converted by a mixture of concentrated nitric and sulphuric acids into 2:4:2':4'-tetranitrodiphenylurethane, yellowish-white, flat prisms, m. p. 184—185°, which reacts further with the hot mixed nitrating acids to give 2:4:6:2':4':6'-hexanitrodiphenylamine. Diphenylurethane reacts in carbon tetrachloride solution with nitrogen peroxide, giving the 4:4'- and the 2:4'-dinitro-derivatives.

Notwithstanding the similarity in structure between diphenyl-

urethane and diphenylnitrosoamine, the former is less readily nitrated than the latter, the nitration at low temperatures and concentrations stopping at the dinitro-stage.

Attempts to synthesise the nitrodiphenylurethanes from ethyl chloroformate and the relevant nitrodiphenylamines were unsuccessful; their constitutions have, however, been proved by hydrolysis to the corresponding nitro-derivatives of diphenylamine.

W. S. N.

**Action of the Oxides and the Oxy-acids of Nitrogen on Ethyl-*o*-tolylurethane.** HUGH RYAN and NICHOLAS CULLINANE (*Proc. Roy. Dublin Soc.*, 1923, 17, 119—124; cf. preceding abstract).—Ethyl-*o*-tolylurethane, a colourless oil, b. p. 225°, is less readily nitrated than diphenylamine; moreover, the ethyl group is slowly eliminated, and the nitro-products are in all cases derived from *o*-tolylurethane.

Nitrogen peroxide (vapour) converts the urethane into oxalic acid and 5-nitro-*o*-tolylurethane, m. p. 137° (Vittenet, A., 1899, i, 756, gives 127°), identical with the product formed by the action of ethyl chloroformate on 5-nitro-*o*-toluidine. In carbon tetrachloride solution, fuming nitric acid converts ethyl-*o*-tolylurethane into 3:5-dinitro-*o*-tolylurethane, slender, white needles, m. p. 159—160°, which could not be further nitrated, and is also produced by the nitration of 5-nitro- or 3-nitro-*o*-tolylurethane; the synthesis of the latter, almost colourless prisms, m. p. 131°, and of 4-nitro-*o*-tolylurethane, by the action of ethyl chloroformate on 3-nitro-*o*-toluidine or 4-nitro-*o*-toluidine, respectively, are described.

4-Nitro-*o*-tolylurethane, m. p. 137° (Vittenet, *loc. cit.*, gives 129°), is converted by heating with fuming nitric acid into slender, white needles, m. p. 193—194° (decomp.), probably 4:5-dinitro-*o*-tolylurethane.

W. S. N.

**Action of the Oxides and the Oxy-acids of Nitrogen on Phenylethylurethane.** HUGH RYAN and ANNA CONNOLLY (*Proc. Roy. Dublin Soc.*, 1923, 17, 125—130; cf. preceding abstracts).—Like other urethanes, phenylethylurethane nitrates with difficulty. Unlike *o*-tolylethylurethane, it yields nitro-derivatives of the tertiary urethane when nitrated at a low temperature, although at moderately high temperatures derivatives of phenylurethane are produced.

Nitrogen peroxide in carbon tetrachloride solution converts the urethane into 4-nitrophenylethylurethane, large, colourless rhombohedra, m. p. 55—56°, and into a dinitro-compound, colourless, rhombic prisms, m. p. 88—89°, probably 2:4-dinitrophenylethylurethane; the former is converted by boiling with alcoholic potash into *p*-nitroethylaniline, but the conversion of the dinitro-compound into 2:4-dinitroethylaniline has not yet been accomplished.

The same two nitro-derivatives are obtained by the action of cold fuming nitric acid on phenylethylurethane, but when the temperature is allowed to rise during the reaction, the chief products are 4-nitrophenylurethane and 2:4-dinitrophenylurethane. A mixture of concentrated nitric and sulphuric acids converts

phenylethylurethane into 2:4-dinitro- and 2:4:6-trinitro-phenylurethanes.

At low concentrations in acetic acid solution and at the ordinary temperature, the urethane is converted very slowly and incompletely by nitric acid into its mononitro- and dinitro-derivatives; but in carbon tetrachloride solution the substances react more readily, with formation of 4-nitrophenylethylurethane.

W. S. N.

**Action of the Oxides and the Oxy-acids of Nitrogen on Phenylbenzylurethane.** HUGH RYAN and JAMES L. O'DONOVAN (*Proc. Roy. Dublin Soc.*, 1923, 17, 131—137; cf. preceding abstracts).

—Like other tertiary aromatic urethanes, *phenylbenzylurethane*, a colourless oil, is difficult to nitrate. The benzyl radicle can, however, be nitrated, as well as the phenyl radicle, without decomposition of the urethane.

Nitrogen peroxide converts the urethane into *p*-nitrophenylbenzylurethane, almost colourless plates, m. p. 70—71°, and a trinitro-(2:4:4'- or 2:2':4'-)-phenylbenzylurethane, long, rhombic crystals, m. p. 110—111°; a little oxalic acid is also formed. The use of cold dilute nitric acid leads to the above mononitro-compound and oxalic acid; at higher concentrations of the acid, the trinitro-derivative is produced. Warm concentrated nitric acid converts the urethane into a tetranitro-derivative, colourless plates, m. p. 126—127°, probably 2:4:2':4'-tetranitrophenylbenzylurethane, and a compound, yellowish-white, silky needles, m. p. 274° (decomp.), probably 2:4:6:2':4'-pentanitrophenylbenzylamine. Secondary reactions also occur leading to *p*-nitrobenzoic acid, 2:4-dinitrophenylurethane, and a compound, yellow, felted needles, m. p. 264° (decomp.), either pentanitrophenylbenzylurethane or trinitrophenylbenzylamine.

The mononitro-derivative (above) is converted on being boiled with alcoholic potash into *p*-nitrophenylbenzylamine; its constitution is thereby established. It is, moreover, different from phenyl-*p*-nitrobenzylurethane, rhombic plates, m. p. 68—69°, which is formed by the condensation of ethyl chloroformate with phenyl-*p*-nitrobenzylamine.

W. S. N.

**Preparation of Arylthiocarbimides.** F. B. DAINS, R. Q. BEWSTER, and C. P. OLANDER (*Univ. Kansas Sci. Bull.*, 1922, 13, 1—14; cf. Hofmann, *Ber.*, 1882, 15, 986; Werner, *T.*, 1891, 59, 400; Dains, *A.*, 1900, i, 390; Anschütz, *A.*, 1910, i, 158; Braun, *A.*, 1904, i, 90; Losanitsch, *A.*, 1892, 55; Heller and Bauer, *A.*, 1902, i, 444).—The authors find that Losanitsch's method (*loc. cit.*) is generally applicable to the preparation of aryl thiocarbimides. As a modification of Heller and Bauer's method (*loc. cit.*), 54 g. of aniline are added with cooling and constant stirring during fifteen minutes to 54 g. of carbon disulphide and 80 g. of 28% ammonia solution. Ammonium phenyldithiocarbamate separates, and after being kept in ice for an hour is collected, washed with ethyl alcohol, and dried on a plate. On keeping, hydrogen sulphide, ammonia, carbon disulphide, aniline,

and thiocarbanilide are formed, the decomposition being hastened when the salt is boiled with water. Ammonium *p*-chloro- and *p*-bromo-phenyldithiocarbamate give 55–60% yields of the substituted thiocarbanilide. With hydrochloric acid, ammonium phenyldithiocarbamate reacts quantitatively according to the equation:  $\text{NHPh-CS-SNH}_4 + 2\text{HCl} = \text{NH}_2\text{Ph.HCl} + \text{CS}_2 + \text{NH}_4\text{Cl}$ . For the production of arylthiocarbimides from ammonium aryl-dithiocarbamates, a salt must be used which will give a stable sulphide and an ammonium salt. Ferrous sulphate, zinc sulphate, copper sulphate, and lead nitrate with ammonium phenyldithiocarbamate, after keeping and distillation with steam, give, respectively, a yield of 3 c.c., 23%, 71.7%, and 77.2% of phenylthiocarbimide. Phenylthiocarbimide is prepared as follows. Ammonium phenyldithiocarbamate is obtained (see above), the mixture being stirred for thirty minutes after addition of the aniline, and then kept for thirty minutes without stirring. The precipitate is dissolved in 80 c.c. of water, 200 g. of lead nitrate in 400 c.c. of water are added with stirring, and the mixture is distilled with steam from a 5-litre flask; the receiver should contain dilute sulphuric acid to prevent formation of thiocarbanilide. Replacement of the ammonium by the sodium salt results in a yield of only 30.2% of phenylthiocarbimide. The barium salt and zinc chloride gave a 37.4% yield, and in the case of the calcium salt very little phenylthiocarbimide is formed, the main product being thiocarbanilide. The following thiocarbimides were prepared: *o*-tolyl- (yield 73.27%), *m*-tolyl-, *p*-tolyl-, *m*-4-xylyl-, *m*. *p*. 31°; *ψ*-cumyl-,  $\alpha$ - and  $\beta$ -naphthyl-, *o*- and *p*-anisyl-, and *p*-phenetidyl-; *m*- and *p*-bromophenyl-, *p*-chlorophenyl-, and *p*-iodophenyl-derivatives were also formed, but ammonium *p*-nitrophenyldithiocarbamate could not be prepared. The success of the method is dependent on the completeness of the formation of the ammonium arylthiocarbamate, on the ease and completeness of separation from the sulphide precipitate, and on the avoidance of side reactions.

CHEMICAL ABSTRACTS.

**Pinacolin Transformations. V. The Transformation of Compounds containing Six- and Seven-membered Carbon Rings.** HANS MEERWEIN and JOSEPH SCHÄFER (*J. pr. Chem.*, 1922, [iii], 104, 289–310; cf. *A.*, 1910, i, 856; 1913, i, 485; 1914, i, 850; 1919, i, 162).—The authors have shown that both 1:1-dimethylcycloheptan-2-ol and 1-methyl-1- $\alpha$ -hydroxyethylcyclohexane give on dehydration a mixture of 1:2-dimethyl- $\Delta^1$ -cycloheptene and  $\Delta^1$ -isopropylcyclohexene, in a proportion which cannot exactly be estimated.

The behaviour of 1:1-dimethylcycloheptan-2-ol is therefore comparable with that of 1:1-dimethylcyclohexan-2-ol, which similarly gives 1:2-dimethyl- $\Delta^1$ -cyclohexene (75%) and  $\Delta^1$ -isopropylcyclopentane; hence, from this comparison, no difference in the stability of six-membered and seven-membered rings can be detected. Nevertheless, whilst the dehydration of 1-methyl-1- $\alpha$ -hydroxyethylcyclopentane gives exclusively 1:2-dimethyl-

$\Delta^1$ -cyclohexene, with formation of a larger ring, the analogous production from 1-methyl-1- $\alpha$ -hydroxyethylcyclohexane of 1:1-dimethyl- $\Delta^1$ -cycloheptene is accompanied by the formation of  $\Delta^1$ -isopropylcyclohexene, by the wandering of a methyl group; moreover, whilst  $\alpha$ -cyclohexyl- $\beta$ -methylpropan- $\alpha\beta$ -diol on dehydration gives 1:1-dimethylcyclohexan-2-one only,  $\alpha$ -cyclohexyl- $\beta$ -methylpropan- $\alpha\beta$ -diol gives, besides 1:1-dimethylcycloheptan-2-one, some 1-acetyl-1-methylcyclohexane. Hence in both cases there is an undoubted resistance to seven-ring formation.

Nevertheless, the ready conversion of six- into seven-membered rings calls for comment, since it is improbable according to Baeyer's strain theory. The authors consider that polymethylene rings assume, as far as possible, strain-free configurations (cf. A., 1922, i, 441; this vol., i, 224; also Baker and Ingold, T., 1923, 123, 122); hence six-membered and larger rings lie in more than one plane. This view appears at first sight to conflict with the difficulty experienced in closing seven-membered and larger rings. The formation of a ring from an open chain must, however, proceed from a configuration of the latter corresponding with the strain-free configuration of the ring (cf. A., 1919, ii, 229). The more complicated the latter, the less frequently will this favourable configuration of the chain occur; hence the small tendency to production of large rings from open-chain substances is explicable without reference to strains (cf. Wojnicz-Sianozencki, A., 1922, i, 330). On the other hand, it is remarked, the strain-free configurations of cyclohexane and cycloheptane being very similar, interconversion of their derivatives requires but little intramolecular rearrangement, and the ease of the change is therefore not surprising.

When the product of the action of sulphuric acid on  $\alpha$ -cyclohexyl- $\beta$ -methylpropan- $\alpha\beta$ -diol (A., 1913, i, 485; cf. Tarboureich, A., 1913, i, 181) is oxidised by means of excess of sodium hypobromite, the 1-methyl-1-acetylcyclohexane is converted into 1-methylcyclohexane-1-carboxylic acid, which can then be separated from the 1:1-dimethylcycloheptan-2-one, b. p.  $190^\circ$ ,  $d_4^{20}$  0.9205,  $n_D^{20}$  1.45694, semicarbazone, long, colourless needles, m. p.  $169-170^\circ$  (Tarboureich, 176°), oxime, tabular crystals, m. p.  $83-85^\circ$ . Reduction of this ketone by means of sodium in moist ethereal solution gives 1:1-dimethylcycloheptan-2-ol, b. p.  $86.8-87.2^\circ/13$  mm.,  $d_4^{20}$  0.9345,  $n_D^{20}$  1.47478, which gives a phenylurethane, long needles, m. p.  $100-101^\circ$ , and is converted in 80% yield, by heating at  $180^\circ$  with zinc chloride, into a mixture of hydrocarbons, b. p.  $155.1-156.3^\circ$ ,  $d_4^{20}$  0.8274,  $n_D^{20}$  1.46073, from which the nitrosochloride of  $\Delta^1$ -isopropylcyclohexene (cf. Wallach, A., 1908, i, 402) and a second nitrosochloride, m. p. about  $118^\circ$ , blue crystals which become colourless (probably that of 1:2-dimethyl- $\Delta^1$ -cycloheptene), have been isolated. Oxidation of the hydrocarbon mixture in glacial acetic acid solution by means of ozone leads to known products, (a)  $\beta\gamma$ -diketononane (Blaise and Köhler, A., 1909, i, 204) derived from 1:2-dimethyl- $\Delta^1$ -cycloheptene, which is therefore present in the mixture; (b) the acid  $\text{CO}_2\text{H}[\text{CH}_2]_4\text{CO}\cdot\text{CHMe}_2$  (Wallach, loc. cit.) derived from  $\Delta^1$ -isopropylcyclohexene. By the action of mag-

nesium methyl iodide on the cold *acid chloride*, b. p.  $86.5^{\circ}/23$  mm., of 1-methylcyclohexane-1-carboxylic acid (from the hypobromite oxidation, see above), 1-acetyl-1-methylcyclohexane can be prepared in relatively large quantities as a mobile oil, b. p.  $186.5-187^{\circ}$ ,  $d_4^{20}$  0.9178,  $n_D^{20}$  1.45484, possessing a strong camphor-like odour, and giving a semicarbazone, thick needles, m. p.  $186^{\circ}$  (Tarboureich,  $158^{\circ}$ ), and an oxime, small, lustrous needles, m. p.  $38-39^{\circ}$  (Tarboureich,  $45^{\circ}$ ). Reduction of the ketone by means of sodium in moist ethereal solution leads to 1-methyl-1- $\alpha$ -hydroxycyclohexane, b. p.  $87.5^{\circ}/13$  mm.,  $d_4^{20}$  0.9312,  $n_D^{20}$  1.47203, a thick, colourless oil, possessing a musty odour characteristic of pinacolyl alcohols; the phenylurethane has not been obtained crystalline. The elimination of water, by heating with zinc chloride, gives an 81% yield of a mixture of *hydrocarbons*, b. p.  $154-156.5^{\circ}$ ,  $d_4^{20}$  0.8270,  $n_D^{20}$  1.46083, which on oxidation by means of ozone leads to the same products as before.

The optical properties of the extracyclic pinacolins and pinacolyl alcohols described in this and preceding communications are tabulated, it being shown that all these compounds exhibit a negative exaltation.

W. S. N.

**Picryl Sulphide. The Binary System: Toluene-Picryl Sulphide.** A. ROCHE and V. THOMAS (*Compt. rend.*, 1923, 176, 586-589).—The picryl sulphide used, after recrystallisation from acetone, melted at  $213^{\circ}$  on the Maquenne block, and almost immediately resolidified, changed colour, and remelted again at  $234^{\circ}$ . In a m. p. tube, the temperatures were  $211^{\circ}$  and  $230.5^{\circ}$ , respectively. It explodes in the neighbourhood of  $300^{\circ}$ . The addition of toluene lowers the temperature of explosion, and it is also more intense. The two constituents of the binary mixture are miscible in all proportions in the fluid state, and no definite combination is formed. The eutectic melts at  $78.3^{\circ}$  and contains 86.5% of toluene. With mixtures of approximately this composition, a phenomenon of double supercooling was observed, the thermometer falling regularly to  $74.5^{\circ}$ , then rising to  $76.65^{\circ}$ , falling again to  $75.1^{\circ}$ , and finally rising to  $78.3^{\circ}$ . The cause of this anomalous behaviour was not ascertained.

G. F. M.

**Effect of Relative Positions of Hydroxyl and Amino-radicals in the Migration of Acetyl from Nitrogen to Oxygen.** L. CHAS. RAIFORD and HAROLD A. IDDLIS (*J. Amer. Chem. Soc.*, 1923, 45, 469-475; cf. A., 1920, i, 156; 1922, i, 931).—Additional evidence is given in support of the view that the migration of the acetyl group from nitrogen to oxygen, when an *o*-acetamidophenol is benzoylated by the Schotten-Baumann method, is probably general. With *p*-acetamidophenols under the same conditions, benzoylation does not cause migration of the acetyl group. This process thus furnishes a further means of distinguishing between *o*- and *p*-aminophenols. The following new compounds are described: 2:6-dibromo-4-acetamidophenyl acetate, m. p.  $172-173^{\circ}$ ; 2:6-dibromo-4-acetamidophenyl benzoate, m. p.  $168^{\circ}$ ; 2:6-dibromo-4-benzamidophenyl acetate, m. p.  $165^{\circ}$ ; 3-bromo-5-acetamido-*o*-tolyl

benzoate, m. p. 196°; 6-bromo-5-benzamido-o-cresol, m. p. 189°; 3-bromo-5-benzamido-o-tolyl acetate, m. p. 130°; 2:4-dibromo-6-acetamido-m-tolyl acetate, m. p. 145—146°; 2:4-dibromo-6-acetamido-m-cresol, m. p. 222°; 2:4-dibromo-6 acetamido-m-tolyl benzoate, m. p. 182—183°; 2:4-dibromo-6-benzamido-m-tolyl acetate, m. p. 179°; 2:6-dibromo-4-acetamido-m-cresol, m. p. 171°, and 2:6-dibromo-4-benzamido-m-tolyl acetate, m. p. 198—199°.

W. G.

**Acetomethylamidophenyl Acetate.** H. T. CLARKE (U.S. Pat. 1434429).—Acetomethylamidophenyl acetate is prepared by adding acetyl chloride beneath the surface of dimethylaminophenyl acetate contained in a bath at 190°.

CHEMICAL ABSTRACTS.

**Preparation of  $\beta$ -Naphthol-4-Sulphonic Acid.** GILBERT T. MORGAN and EVELINE JONES (*J. Soc. Chem. Ind.*, 1923, 42, 97—98r).—The preparation of  $\beta$ -naphthol-4-sulphonic acid from naphthalene-1-diazo-2-oxide-4-sulphonic acid, a commercially available product, is described. Sixty g. of the latter were heated with 900 c.c. of absolute alcohol in a reflux apparatus for about twenty-one hours and the resulting solution neutralised with barium carbonate. Alcohol was distilled off, the residual thick paste dissolved in water and the solution decolorised with animal charcoal, concentrated, and the residue dried over sulphuric acid.  $\beta$ -Naphthalene-1-azo- $\beta$ -naphthol-4-sulphonic acid, p-nitrobenzene-1-azo- $\beta$ -naphthol-4-sulphonic acid, and p-toluene-1-azo- $\beta$ -naphthol-4-sulphonic acid were prepared from the resulting barium  $\beta$ -naphthol-4-sulphonate, which was obtained as a hard, friable mass extremely soluble in water. The three azo-colours dyed on wool and silk in varying shades of red.

J. S. G. T.

**The 1:2-cycloHexanediols and o-Chlorocyclohexanol.** MARCEL GODCHOT (*Compt. rend.*, 1923, 176, 448—450).—The author finds for the 2-chlorocyclohexan-1-ol, as prepared by Detœuf (Thesis, Paris, 1920), or by Osterberg and Kendall (*A.*, 1920, i, 101), the m. p. 29°, when it has been carefully purified. It gives a phenylurethane, m. p. 97—98°, and with alcoholic potassium hydroxide the ether oxide described by Brunel (*A.*, 1905, i, 695). The chlorohydrin reacts with silver acetate to give the monoacetate of cyclohexan-1:2-diol, b. p. 122—124°/10 mm.,  $d^{15}_4$  1.091,  $n^{15}_D$  1.4685. This acetate on hydrolysis with aqueous-alcoholic potassium hydroxide gives the cyclohexanediol, m. p. 104°. The author considers that his results support the view of Böseken and co-workers (*A.*, 1921, i, 663) that the diol is a *cis-trans*-compound.

W. G.

**Rings through the Meta- and Para-positions of Benzene. A Study of certain Ethers of Resorcinol and m-Aminophenol.** W. C. WILSON and ROGER ADAMS (*J. Amer. Chem. Soc.*, 1923, 45, 528—540).—An attempt has been made to produce ring structures through the meta- and para-positions of benzene by starting with various resorcinol ethers and with m- and p-aminophenol ethers, but in no instance was a meta- or para-ring obtained, such as might be expected from the reactions of compounds similar in

structure except for the presence of the oxygen atom or atoms. These results tend to confirm previous observations (cf. Mohr, A., 1919, ii, 229; and von Braun, A., 1913, i, 197; 1919, i, 40; 1920, i, 87), that a very definite kind and number of atoms are necessary for the formation of meta- and para-rings. Apparently, if there is any other reaction which has the slightest tendency to take place in preference to the formation of meta- and para-rings, such a reaction will occur. Thus when resorcinol di- $\gamma$ -cyanopropyl ether was reduced according to the method used by von Braun (*loc. cit.*) for *m*-xylylene dicyanide, not a trace of a ring compound was formed, but only the corresponding diamine in excellent yield. Further, by distillation of the monohydrochloride of this diamine, no ring compound was produced. Similarly, it was not possible to obtain a ring compound by treating resorcinol di- $\gamma$ -iodopropyl ether with a primary amine. The same ether and sodium under a variety of conditions gave no compound having a ring structure.

A number of resorcinol ethers have been prepared as follows. *Resorcinol di- $\beta$ -bromoethyl ether*, m. p. 94.5–95°, b. p. 166–167°/9 mm., was obtained by the interaction of ethylene bromide and sodium resorcinoxide in absolute alcohol. Attempts to prepare *resorcinol di- $\gamma$ -bromopropyl ether*, m. p. 67°, b. p. 204–206°/6 mm., by the same process gave principally a mixture of three other compounds, namely, *resorcinol  $\gamma$ -bromopropyl allyl ether*,

$\text{CH}_2\text{CH}:\text{CH}_2\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CH}_2\text{Br}$ ,  
m. p. 88–89°, *resorcinol diallyl ether*,  $\text{C}_6\text{H}_4(\text{O}\cdot\text{CH}_2\cdot\text{CH}:\text{CH}_2)_2$ , b. p. 166–168°/12 mm.,  $d_{20}^{20}$  1.1645,  $n_D^{20}$  1.5672, and a substance which was probably trimethylene  $\gamma$ -bromopropoxyphenyl allyloxyphenyl ether,  $\text{CH}_2\text{Br}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot[\text{CH}_2]_3\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{CH}_2\cdot\text{CH}:\text{CH}_2$ , m. p. 119–120°. *Resorcinol di- $\gamma$ -bromopropyl ether* was best prepared by heating together a mixture of resorcinol, potassium carbonate, and trimethylene bromide in aqueous acetone. From this ether, by the action of sodium iodide in aqueous acetone, *resorcinol di- $\gamma$ -iodopropyl ether*, m. p. 88–89°, was obtained. *Resorcinol di- $n$ -propyl ether*, b. p. 127–128°/12 mm.,  $d_{20}^{20}$  1.035,  $n_D^{20}$  1.5138, on bromination gave a *bromide*, m. p. 81°. The iodo-ether, when heated with *n*-amylamine, gave *resorcinol di- $\gamma$ -*n*-amylaminopropyl ether*, b. p. 249–252°/10 mm., isolated as its *dihydrochloride*, m. p. 287°. When boiled with sodium cyanide in aqueous alcohol, the iodo-ether was converted into *resorcinol di- $\gamma$ -cyanopropyl ether*, m. p. 31–32°, b. p. 236–237°/7 mm., which, when reduced with sodium in alcohol, yielded *resorcinol di- $\delta$ -aminobutyl ether*, b. p. 208–209°/7 mm.,  $d_{20}^{20}$  1.0589,  $n_D^{20}$  1.5315, giving a *monohydrochloride*, m. p. 233–234°, and a *dihydrochloride*, m. p. 248–249°. The monohydrochloride, when heated, decomposed, giving resorcinol, pyrrolidine, and *resorcinol mono- $\delta$ -aminobutyl ether*, m. p. 119–119.5°, b. p. 198–204°/8 mm., isolated as its *hydrochloride*, m. p. 159–161°. This amine, when dissolved in sodium hydroxide solution and shaken with *p*-nitrobenzoyl chloride, yielded *resorcinol di- $\delta$ -p-nitrobenzamidoethyl ether*, m. p. 123–124°.

When *m*-nitrophenol was heated with trimethylene bromide in the presence of sodium ethoxide, *m-nitrophenyl  $\gamma$ -bromopropyl ether*,

b. p. 186—188°/7 mm.,  $d_{20}^{25}$  1.513,  $n_D^{25}$  1.5700, was obtained, and this on reduction with stannous chloride and hydrochloric acid gave *m*-aminophenyl  $\gamma$ -bromopropyl ether, isolated as its hydrochloride, m. p. 114—115°. The free amine, when distilled, was decomposed, giving 6-aminochroman, b. p. 140—142°/7 mm.,  $d_{20}^{25}$  1.1549,  $n_D^{25}$  1.5944, which gave a hydrochloride, m. p. 158—160° (decomp.), a picrate, m. p. 182—183° (decomp.), a chloroplatinate, m. p. 224—225°, an acetyl derivative, and a benzenesulphonyl derivative, m. p. 148—148.5°. When the aminochroman was diazotised and the product coupled with  $\beta$ -naphthol, a brilliant red compound was obtained.

*m*-Nitrophenyl allyl ether, m. p. 31.5—32°, b. p. 136—137°/8 mm., was prepared from allyl bromide and *m*-nitrophenol, and on reduction yielded *m*-aminophenyl allyl ether, b. p. 120—122°/5 mm.,  $d_{20}^{25}$  1.0891,  $n_D^{25}$  1.5708, giving a hydrochloride, m. p. 145—146°, an acetyl derivative, and a benzenesulphonyl derivative, m. p. 83—83.5°.

Under similar conditions, starting with *p*-nitrophenol, there were prepared *p*-nitrophenyl  $\beta$ -bromoethyl ether, m. p. 64°; *p*-aminophenyl  $\beta$ -bromoethyl ether, m. p. 84°, and its hydrochloride, m. p. 196°. This amino-ether, when heated, gave no definite product.

W. G.

**Structure of Benzene.** MAURICE L. HUGGINS (*J. Amer. Chem. Soc.*, 1923, 45, 264—278).—The experimental data obtained by Hull (*Physical Rev.*, 1917, 10, 692) and by Debye and Scheerer (*A.*, 1917, ii, 437) indicate a structure for graphite composed of layers of closely packed benzene complexes of the type originally proposed by Körner. When similar closely packed layers in crystals of benzene and many of its derivatives are assumed, the dimensions of the benzene hexagon can be calculated from the crystallographic data. This has been done for the following substances, for which the half length,  $l$ , and the half width,  $w$ , are recorded: quinol,  $l=2.47$ ,  $w=2.14$ ; benzene,  $l=2.46$ ,  $w=2.19$ ; resorcinol,  $l=2.52$ ,  $w=2.08$ ; *p*-chloroaniline,  $l=2.47$ ,  $w=2.16$ ; pyrocatechol,  $l=2.62$ ,  $w=2.11$ ; *p*-dichlorobenzene,  $l=2.54$ ,  $w=2.13$ ; triphenylcarbinol,  $l=2.45$ ,  $w=2.13$ ; triphenylbenzene,  $l=2.44$ ;  $w=2.16$ ; tribenzylcarbinol,  $l=2.42$ ,  $w=2.11$ ; tribenzylsilicol,  $l=2.48$ ,  $w=2.16$ ; and triphenylmethane,  $l=2.47$ ,  $w=2.16$ . These values are very near to the values obtained for graphite,  $l=2.47$ ,  $w=2.14$  (Hull),  $l=2.52$ ,  $w=2.18$  (Debye and Scheerer). The arrangement of atoms, molecules, and electrons in the crystal has been partly determined.

J. F. S.

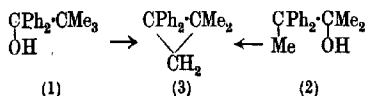

**The Phenylalanine Series. II. Synthesis of 3:4-Dihydroxyphenylethylamine.** E. WASER and H. SOMMER (*Helv. Chim. Acta*, 1923, 6, 54—61).—A new synthesis of 3:4-dihydroxyphenylethylamine was accomplished, starting from tyramine (*p*-hydroxyphenylethylamine). Tyramine was nitrated in aqueous suspension with nitric acid at 0—5°, and 3-nitro-4-hydroxyphenylethylamine nitrate separated. It crystallises in rosettes of yellow needles, m. p. 208° (decomp.). The free base forms microscopic prisms

or leaflets, varying from yellow to orange in colour, according to the solvent from which they are obtained, m. p.  $217^{\circ}$  (corr., decomp.). It is soluble in 200 parts of cold or 120 parts of hot water, and gives no colour reaction with Millon's reagent or with ferric chloride. The *hydrochloride* forms large, yellowish-brown leaves, decomposing, without melting, at  $214.5^{\circ}$  (corr.). The *chloroplatinate* forms golden-yellow needles decomposing at  $265^{\circ}$ , and the *picrate* deep yellow prisms, m. p.  $204^{\circ}$ . From the nitration liquor a small amount of 3:5-dinitro-4-hydroxyphenylethylamine was obtained, an orange-red, microcrystalline powder, decomposing at  $290^{\circ}$ . The *nitrate* crystallises in well-developed, yellow prisms, m. p.  $163^{\circ}$  (corr., decomp.), and the *picrate* forms a yellow, microcrystalline powder, m. p.  $196^{\circ}$ . It was identified by conversion into 3:5-dinitro-4-hydroxybenzoic acid. The reduction of 3-nitrotyramine was best accomplished with hydrogen in presence of platinum in dilute hydrochloric acid. 3-Amino-4-hydroxyphenylethylamine (aminotyramine) forms colourless, microscopic leaflets, m. p.  $145-147^{\circ}$  (corr.). It is soluble in 160 parts of cold or 50 parts of boiling water, from which it crystallises as a *monohydrate*, m. p.  $127^{\circ}$ . With Millon's reagent, it gives a yellow colour in the cold, becoming turbid and brown in the hot. Ferric chloride gives a deep reddish-violet colour, becoming yellow on addition of alkali, brownish-red with sodium acetate. It reduces an ammoniacal silver solution in the cold and Fehling's solution in the hot. The diazotised base gives a brownish-red colour with  $\alpha$ -naphthol. The base also gives the tyrosinase reaction with potato, but not so strongly as tyrosine. The *dihydrochloride* forms star- or feather-shaped groups of needles, m. p.  $305^{\circ}$  (corr., decomp.). This, when injected into the jugular vein of a dog caused a sharp rise of blood pressure. The *monopicrate* forms dark brown, pointed prisms, m. p.  $204.5^{\circ}$  (corr., decomp.); the *dipicrate* forms bright brownish-yellow leaflets, m. p.  $212^{\circ}$  (corr., decomp.). Attempts to obtain aminotyramine by decarboxylation of aminotyrosine gave a very poor yield.

3:4-Dihydroxyphenylethylamine was obtained by diazotising aminotyramine in sulphuric acid solution and running the diazo-solution into a boiling concentrated solution of copper sulphate. The *hydrochloride* forms groups of needles, m. p.  $237^{\circ}$  (corr., decomp.); the *picrate* forms brownish-yellow crystals, m. p.  $189^{\circ}$  (corr.). 3:4-Dihydroxyphenylethylamine gives a red colour with Millon's reagent, and a green colour, destroyed by excess of the reagent, with ferric chloride. It reduces an ammoniacal silver solution in the cold and Fehling's solution in the hot. E. H. B.

**Molecular Transposition in the Diphenyl- $\psi$ -butylcarbinol Series.** (MME) PAULINE RAMART (*Compt. rend.*, 1923, 176, 684-686).—The action of acetyl chloride and acetic anhydride on diphenyl- $\psi$ -butylcarbinol results in the formation of a chloro-compound and a hydrocarbon, the former having the constitution  $\text{CMePh}_2\text{-CMe}_2\text{Cl}$  (A., 1922, i, 34). The same hydrocarbon has now been obtained by the dehydration of diphenyl- $\psi$ -butylcarbinol (1), and the tertiary alcohol (2) by the action of heat in presence of

infusorial earth, and from the corresponding chloro-compounds by the action of pyridine in sealed tubes at 120°.

The alcohol (2) was obtained by the action of 2 mols. of magnesium methyl iodide on ethyl  $\alpha$ -diphenylpropionate, and the chloro-compounds were obtained by the action of thionyl chloride on the alcohols. The identity of the four hydrocarbons obtained and that obtained from the carbinol (1) by the action of acetyl chloride and acetic anhydride was proved by the identity of the chloro-compounds obtained from them by the action of hydrogen chloride at -10°, by the identity of the tribromides, m. p. 200° (with decomp.), obtained by the action of bromine, by their comparative indifference to acid or alkaline permanganate, and by the identity of their physical constants,  $d_4^{20}$  1.008,  $n_D^{20}$  1.5746. The hydrocarbon is therefore regarded as an intermediate product in the formation of the chloro-compound,  $\text{CMePh}_2\cdot\text{CMe}_2\text{Cl}$ , from diphenyl- $\psi$ -butylcarbinol, and as having the cyclopropane structure (3).

G. F. M.

**Ethers of Triphenylcarbinol.** BUECKHARDT HELFERICH, PAUL ELIAS SPIDEL, and WALTER TOELDTE (*Ber.*, 1923, 56, [B], 766-770).—Triphenylmethyl chloride reacts with alcohols in the presence of anhydrous pyridine at the atmospheric temperature or when warmed to give the corresponding ethers:  $\text{CPh}_3\text{Cl} + \text{R}\cdot\text{OH} = \text{R}\cdot\text{O}\cdot\text{CPh}_3 + \text{HCl}$ . Since the action proceeds in the presence of an excess of pyridine, it is particularly suitable for compounds which are sensitive towards acids. The ethers generally crystallise readily and appear to be adapted to the identification and possibly the purification of alcohols. They appear to be generally stable towards boiling alcoholic alkali, but are readily hydrolysed by dilute methyl-alcoholic hydrogen chloride at the atmospheric temperature to the alcohol and triphenylcarbinyl methyl ether. The introduction of the triphenylmethyl group is therefore serviceable for the protection of hydroxyl groups.

The following individual compounds are described: *triphenylmethyl isopropyl ether*,  $\text{Pr}^s\cdot\text{O}\cdot\text{CPh}_3$ , colourless needles, m. p. 113°; *triphenylmethyl propyl ether*, colourless plates or prisms, m. p. 55°; *triphenylmethyl cetyl ether*, colourless plates or prisms, m. p. 40-41°; *triphenylmethyl allyl ether*, colourless plates or prisms, m. p. 76°; *triphenylmethyl cyclohexyl ether*, colourless prisms, m. p. 103°; *triphenylmethyl hydroxyethyl ether*,  $\text{OH}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{O}\cdot\text{CPh}_3$ , prisms or plates, m. p. 98-100°, the corresponding *bistriphenylmethyl ethylene ether*, prisms or plates, m. p. 185-186°; *triphenylmethyl  $\alpha$ -glycerol ether*,  $\text{OH}\cdot\text{CH}_2\cdot\text{CH}(\text{OH})\cdot\text{CH}_2\cdot\text{O}\cdot\text{CPh}_3$ , m. p. 92-94°; (1) *glycerol  $\alpha$ -bistriphenylmethyl ether*, small prisms, m. p. 170-171°; *pyrocatechol bistriphenylmethyl ether*, small plates, m. p. 206-208°; *pyrocatechol triphenylmethyl ether*, needles, m. p. about 258°

after darkening at  $245^{\circ}$ , which, however, is stable towards alcoholic hydrogen chloride, and hence, possibly, has a different constitution.  
H. W.

**Influence of Substitution in the Components on Equilibria in Binary Solutions. XXXIX. Some Binary Systems of Triphenylmethane, Triphenylcarbinol, and Trimethylcarbinol with other Components.** ROBERT KREMANN, OTTO MAUERMANN, ROBERT MÜLLER II, and WILHELM RÖSLER (*Monatsh.*, 1923, 43, 321—333).—Previous examination of the system triphenylmethane-*m*-phenylenediamine afforded no evidence for the existence of a compound (A., 1922, i, 131). Repetition of the work confirms this; there is formed simply a eutectic at  $58^{\circ}$  and 4% of triphenylmethane. The latter with *o*-phenylenediamine gives a eutectic at  $76.5^{\circ}$  and 12.5% of triphenylmethane. With *m*-phenylenediamine, the hydrocarbon gives two liquid layers in the region 25—93% of triphenylmethane, the (constant) temperature of primary crystallisation being  $81^{\circ}$ . In the case of *o*-phenylenediamine, the same holds for the region 29—50% triphenylmethane ( $89^{\circ}$ ). 2:4-Dinitrophenol and triphenylmethane do not form a compound, but merely a simple eutectic at  $81^{\circ}$  (86% hydrocarbon). Triphenylmethane and triphenylcarbinol give a simple eutectic at  $78^{\circ}$  and 17% of carbinol. *o*-Nitrophenol, contrary to expectation (steric effects), behaves like its meta- and para-isomerides with trimethylcarbinol, a compound of the type 1 phenol+2 carbinol being formed in all three cases (corresponding with 51.6% carbinol) (cf. A., 1895, ii, 205; 1897, ii, 476).

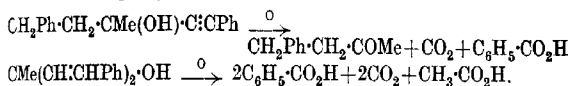

Triphenylcarbinol and 2:4-dinitrophenol form a simple eutectic only, at  $100^{\circ}$  and 19% carbinol. Trimethylcarbinol, on the other hand, gives, with this phenol, an equimolecular compound, m. p.  $89^{\circ}$  (28.7% carbinol). (Eutectic with phenol at  $85^{\circ}$  and 17% carbinol, that with triphenylcarbinol at  $20^{\circ}$  and 97%.)

Naphthalene does not form compounds with either trimethyl- or triphenylcarbinol, but only simple eutectics at  $19^{\circ}$  and 95% trimethylcarbinol and at  $69^{\circ}$  and 30% triphenylcarbinol, respectively. The fact that  $\alpha$ - and  $\beta$ -naphthylamines form compounds with these carbinols, whilst other amines previously examined do not (A., 1919, ii, 457, 458), cannot therefore be attributed to peculiar compound-forming properties of the naphthalene nucleus. E. E. T.

**Addition of Hydrogen to Acetylene Derivatives. X. Addition of Hydrogen to Diphenylphenylacetylenylcarbinol.** J. S. ZALKIND and (MILE) N. CICHANOVA (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 19—23; cf. A., 1916, i, 260).—Diphenylphenylacetylenylcarbinol,  $\text{CPh}_2\text{C}(\text{CPh}_2)\text{OH}$ , is reduced by the Sabatier method, using palladium as catalyst. No break in the rate of addition could be observed after the addition of 50% of the possible hydrogen, i.e., the process did not tend to stop with the formation of an ethylenic linking. Increase in the quantity of catalyst used accelerated the reaction,  $K$  increasing in the ratio 1:3.5:17 when the quantity of catalyst is increased as 1:2:5. The reduction

product was  $\alpha\gamma$ -triphenylpropan- $\alpha$ -ol, m. p. 85–87°. The action of bromine on the original carbinol was also investigated, and a dibromide, m. p. 99–100°, prepared. R. T.

**Addition of Hydrogen to Acetylene Derivatives. XI. Addition of Hydrogen to Alcohols having Two Triple Linkings.** J. S. ZALKIND (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 23–33; cf. A., 1916, i, 260).—Diphenylacetylenylmethylcarbinol,  $\text{CMe}(\text{C}:\text{CPh})_2\cdot\text{OH}$ , is reduced by the Sabatier method, using a palladium catalyst. As in previous cases (*loc. cit.*), addition of hydrogen leads to complete saturation of the acetylenic linkings, with no tendency to stop at the formation of ethylenic linkings. The reduction product is an oil,  $\gamma$ -hydroxy- $\alpha$ -diphenyl- $\gamma$ -methylpentane,  $d_4^{20}=1.0334$ ,  $n_D^{20}=1.55153$ , giving, from aqueous alcohol crystals, m. p. 51°, containing  $1\text{H}_2\text{O}$ . If the reduction process is stopped when half the possible hydrogen has been added, a mixture of unchanged carbinol, of saturated substance, and of  $\gamma$ -hydroxy- $\alpha$ -diphenyl- $\gamma$ -methyl- $\Delta^3$ -pentadiene,  $\text{CMe}(\text{CH}:\text{CHPh})_2\cdot\text{OH}$ , b. p. 210–212°/13 mm.,  $d_4^{20}=1.0638$ ,  $n_D^{20}=1.5580$ , is obtained. In order to prove that the product of reduction is not  $\delta$ -phenyl- $\beta$ -phenylacetylenylbutan- $\beta$ -ol,  $\text{CH}_2\text{Ph}\cdot\text{CH}_2\cdot\text{CMe}(\text{OH})\cdot\text{C}:\text{CPh}$ , the latter compound was synthesised from benzylacetone and magnesium phenylacetylenyl bromide. The oxidation of this compound leads to the production of benzylacetone and benzoic acid, whilst the oxidation of the diethylenic compound gives a mixture of benzoic and acetic acids, in the following way :

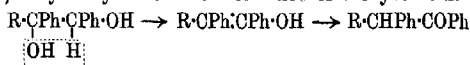

R. T.

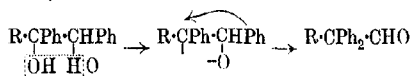

**Semipinacolic and Hydrobenzoinic Transpositions in the Alkylhydrobenzoin Series. Alkylhydrobenzoins with a Branched Chain. I. isoPropyl, isoButyl, and isoAmyl Chains.** M. TIFFENEAU and A. ORÉKHOFF (*Bull. Soc. chim.*, 1923, [iv], 33, 195–218).—The alkyl group in the alkylhydrobenzoins exercises a distinct and regular influence on the manner in which the dehydration of these substances occurs by the action of dilute or concentrated sulphuric acid. The results are interpreted in the light of Werner's ideas on variable affinity. When the affinity between the alkyl group and the rest of the molecule is strong, that of the tertiary hydroxyl is correspondingly weakened, and on dehydration it is eliminated with either the hydrogen contiguous to the secondary hydroxyl [vinyl dehydration (1)] or the hydrogen of the secondary hydroxyl [hydrobenzoin transformation (2)]. If, on the other hand, the affinity between the alkyl group and the rest of the molecule is feeble, as, for example, in the case of the isopropyl group, that of the tertiary hydroxyl is strengthened, and it is the secondary hydroxyl which is eliminated with the hydrogen of the tertiary hydroxyl [semipinacolic trans-

position (3)]. These reactions are expressed by the following schemes :

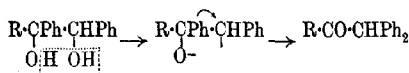

(1) Vinyl dehydration with formation of deoxybenzoins

(2) Hydrobenzoin transposition with formation of alkyl diphenyl acetaldehydes

(3) Semipinacolin transposition with formation of benzhydryl alkyl ketones

The dehydrating agent used also has a definite bearing on the sense of the reaction. Concentrated sulphuric acid augments the stability of the tertiary hydroxyl, or, if its affinity is weakened by the adjacent alkyl group, then it determines its elimination according to (1) above. Dilute sulphuric acid, on the other hand, has no effect on the stability of the hydroxyl but determines the aldehyde formation (2) by elimination of the hydrogen of the secondary hydroxyl. The following substances were prepared during the course of the research:  $\alpha\beta$ -Diphenyl- $\gamma$ -methylbutane- $\alpha\beta$ -diol (isopropylhydrobenzoin) prepared from benzoin and magnesium isopropyl bromide, forms colourless needles, m. p. 107–108°. On dehydration with cold concentrated sulphuric acid, the semipinacolin transformation occurs exclusively, with formation of  $\alpha\alpha$ -diphenyl- $\gamma$ -methylbutan- $\beta$ -one, colourless needles, m. p. 74–75°. For purposes of identification, this ketone was also prepared from diphenylacetaldehyde and magnesium isopropyl bromide, the resulting secondary alcohol,  $\alpha\alpha$ -diphenyl- $\gamma$ -methylbutan- $\beta$ -ol, b. p. 188–189°/16 mm., being converted into the ketone by oxidation with chromic acid. The isomeric ketone  $\alpha\beta$ -diphenyl- $\gamma$ -methylbutan- $\alpha$ -one (isopropyldeoxybenzoin), which was synthesised from deoxybenzoin and isopropyl bromide, formed needles, m. p. 70–71°, could not be found in the reaction mixture resulting from the dehydration of isopropylhydrobenzoin, and the vinyl dehydration (1) did not therefore occur at all. The dehydration of isopropylhydrobenzoin by treating with dilute sulphuric acid gave a mixture of the above  $\alpha\alpha$ -diphenyl- $\gamma$ -methylbutan- $\beta$ -one and  $\alpha\alpha$ -diphenylisobutaldehyde, a viscous liquid, b. p. 184–186°/15 mm.,  $d_4^{20}$  1.0522, produced according to the hydrobenzoin transformation (2). Its semicarbazone melts at 190–191°, and oxime at 93–94°. isobutylhydrobenzoin gives on dehydration with oxalic acid exclusively the substituted aldehyde,  $\alpha\alpha$ -diphenyl- $\gamma$ -methylbutaldehyde, a yellow oil, b. p. 195–196°/15 mm.,  $d_4^{20}$  1.035, forming a

*semicarbazone*, m. p. 147—148°, and an *oxime*, m. p. 153—154°. With concentrated sulphuric acid, vinyl dehydration occurs exclusively with formation of *isobutyldeoxybenzoin*. No trace of the isomeric ketone  $\alpha\alpha$ -diphenyl- $\delta$ -methylpentan- $\beta$ -one, m. p. 37—38°; *semicarbazone*, m. p. 168—169°, could be found in the mother-liquors. This ketone was synthesised by oxidation of  $\alpha\alpha$ -diphenyl- $\delta$ -methylpentan- $\beta$ -ol, a yellow oil, b. p. 185—195°/16 mm.  $\alpha\beta$ -Diphenyl- $\epsilon$ -methylhexan- $\alpha\beta$ -diol (*isoamylhydrobenzoin*) prepared from magnesium *isoamyl* bromide and benzoin, forms fine needles, m. p. 127—128°, and on dehydration with weak acids gives only the aldehyde (reaction 2),  $\alpha\alpha$ -diphenyl- $\delta$ -methylhexaldehyde, b. p. 205—210°/17 mm.; *semicarbazone*, m. p. 133—134°. With cold concentrated sulphuric acid, on the other hand, the reaction proceeds to the extent of about one-third according to the semipinacolin transformation and two-thirds vinyl dehydration. The former product,  $\alpha\alpha$ -diphenyl- $\epsilon$ -methylhexan- $\beta$ -one, forms a viscid oil, b. p. 205—210°/21 mm.; *semicarbazone*, m. p. 139—140°, and was identified by synthesis from  $\alpha\alpha$ -diphenyl- $\epsilon$ -methylhexan- $\beta$ -ol, a viscous liquid, b. p. 218—220°/26 mm., which was prepared from magnesium *isoamyl* bromide and diphenylacetaldehyde. The isomeric substance  $\alpha\beta$ -diphenyl- $\epsilon$ -methylhexan- $\alpha$ -one (*isoamyldeoxybenzoin*) forms small, colourless needles, m. p. 62—63°, and gives a *semicarbazone*, m. p. 127—128°. It was identified by synthesis from deoxybenzoin and *isoamyl* bromide. G. F. M.

**Addition of Hydrogen to Acetylene Derivatives. XII.**  
**Addition of Hydrogen to Diphenylbutinenediols and to the Acetyl Ester of Diphenylbutinenediol.** J. S. ZALKIND and (MLLE) Z. NEISCHTAB (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 34—42; cf. *ibid.*, 1914, 46, 1532; 1917, 49, 135).— $\alpha\delta$ -Diphenylbutinene- $\alpha\delta$ -diol,  $\text{OH}\cdot\text{CHPh}\cdot\text{C}\equiv\text{C}\cdot\text{CHPh}\cdot\text{OH}$  (A., 1914, ii, 258), is reduced by the Sabatier method, using a palladium catalyst. This compound exists in two stereoisomeric forms, melting at 140° and 102°, respectively, and both forms were examined. The velocity of reaction for both diminishes considerably after the triple bond has been changed to double, although it is still much greater than for ditertiary alcohols. By varying the quantity of catalyst in the order 1 : 2 : 3 : 5,  $K$  increased as 1 : 4 : 8 : 17. Whilst for both forms two space isomerides of the ethylenic reduction product are possible, only one form, m. p. 151°, is obtained from the less fusible isomeride, and two forms from the other, one m. p. 151—152°, but different from the one obtained previously, and the other an oil. The reduction of the diacetyl esters is next examined. This is much more rapid and complete than for the alcohols, and results in the production of  $\alpha\delta$ -diphenylbutane. No sharp break occurs with the formation of the ethylenic linking, but at saturation a rapid increase in the velocity of the reaction occurs, due to the reduction of the acetyl groups. By stopping the process when 25% of the possible hydrogen has been added on, the *diacetyl* ester, m. p. 97·5°, of the ethylenic reduction product, m. p. 152°, previously prepared, is obtained. R. T.

**Influence of Substitution in the Components on Equilibrium in Binary Solutions. XL. The Equilibrium in Binary Solutions of Acid Amides with Acid Anhydrides and with Acids.** ROBERT KREMANN, OTTO MAUERMANN, and VIKTOR OSWALD (*Monatsh.*, 1923, 43, 335—343).—Acetamide and benzoic anhydride form an equimolecular compound, m. p. about 84°, the eutectics lying at 68° (25% mol. of anhydride) and 38° (93% mol. of anhydride). The binary systems (1) acetamide-acetic anhydride, (2) benzamide-benzoic anhydride, and (3) benzamide-acetic anhydride were examined. A complete examination of (1) and (3) could not be made (i.e., beyond the limits 0—90% of acetic anhydride), owing to solubility effects, but a complete curve was obtained for (2), and shows the existence of a eutectic at 37° and 92% mol. of benzoic anhydride. Examination of the primary crystallisation curve for the system acetamide-acetic acid reveals the probable existence of an equimolecular compound (—5·5° and 50·5% acetic acid), this, with acetic acid, forming a eutectic at —16·5° and 69·5% acetic acid. Benzoic acid and benzamide form a eutectic at 78—79·5° (45·5—47·5% benzoic acid). Acetic acid and benzamide give a eutectic at —2° and 73% acid, benzoic acid and acetamide giving a eutectic at 38° and 56% acid. E. E. T.

**Production of Esters of Aromatic Acids [ $\gamma$ -Dialkylamino-propyl Aminobenzoates].** THE ABBOTT LABORATORIES (Brit. Pat. 191122).— $\gamma$ -Dialkylaminoalkyl esters of aromatic acids in general, and particularly  $\gamma$ -dialkylamino-*n*-propyl benzoates and aminobenzoates in which at least one of the alkyl groups is larger than an ethyl group, are obtained by heating the corresponding  $\gamma$ -halogeno-alkyl esters with a dialkylamine. The  $\gamma$ -dialkylamino-*n*-propyl aminobenzoates and their salts possess valuable local anæsthetic properties, and a specific example of their preparation is given:  $\gamma$ -bromo-*n*-propyl *p*-nitrobenzoate is heated for four hours at 60° with an equal weight of dibutylamine, the excess of amine is then removed by washing with water and distillation with steam, the residue is dissolved in benzene and extracted with dilute hydrochloric acid, the hydrochloride layer is separated and rendered alkaline, and the free base extracted with benzene. The  $\gamma$ -di-*n*-butylamino-*n*-propyl *p*-nitrobenzoate thus obtained is converted on reduction with iron and hydrochloric acid into the corresponding aminobenzoate, which is isolated as its hydrochloride or other suitable salt. *p*-Aminobenzoyl- $\gamma$ -di-*n*-butylamino-*n*-propanol hydrochloride is a crystalline solid, m. p. 151—152°. The hydrobromide melts at 143°, and the sulphate at 100°. Alternatively to the above method of preparation, the bromopropyl nitrobenzoate may first be reduced to  $\gamma$ -bromo-*n*-propyl *p*-aminobenzoate, m. p. 81·5°, and then afterwards condensed with dibutylamine. G. F. M.

**The Addition of Bromine to the  $\alpha$ - and  $\beta$ -Chloro- and Bromo-cinnamic Acids and their Esters.** J. J. SUDBOROUGH and GWYLYM WILLIAMS (*J. Indian Inst. Sci.*, 1923, 5, 107—118).—The addition of bromine in chloroform solution takes place much

more readily in diffused daylight than in the dark; the esters are more reactive than the free acids, and the  $\beta$ -halogenated compounds than the  $\alpha$ -halogenated compounds.  $\alpha$ -Bromocinnamic acid and  $\alpha$ -bromoallocinnamic acid and their methyl esters give the same  $\alpha\beta$ -tribromo- $\beta$ -phenylpropionic acid and *methyl  $\alpha\beta$ -tribromo- $\beta$ -phenylpropionate*, respectively, the former melting at 152–153°, and the latter at 47–48°. Similarly, the two stereoisomeric  $\beta$ -bromocinnamic acids and their methyl esters yield identical products,  *$\alpha\beta\beta$ -tribromo- $\beta$ -phenylpropionic acid*, m. p. 146–147° (decomp.), and *methyl  $\alpha\beta\beta$ -tribromo- $\beta$ -phenylpropionate*, m. p. 42–43°. The latter crystallises in tufts of slender needles. From the stereoisomeric  $\beta$ -chlorocinnamic acids, two different dibromides would theoretically be expected, but only one  *$\beta$ -chloro- $\alpha\beta$ -dibromo- $\beta$ -phenylpropionic acid* was obtained. It formed colourless prisms from chloroform, m. p. 143–144°. Both  $\alpha$ -chlorocinnamic acids, however, gave a mixture of isomeric dibromides, and attempts to separate them were not successful. G. F. M.

**Products of the Distillation of  $\alpha$ -Truxillic Acid.** Isolation of a Fourth Truxillic Acid. HANS STOBBE and FRITZ ZSCHOCK (*Ber.*, 1923, 56, [B], 676–678).—The dry distillation of  $\alpha$ -truxillic acid yields *trans*-cinnamic acid, stilbene (which is probably derived secondarily from *trans*-cinnamic acid and not directly from  $\alpha$ -truxillic acid), a substance, m. p. 192–194°, which has not been definitely characterised,  $\gamma$ -truxillic anhydride, m. p. 189–190°, and  *$\eta$ -truxillic anhydride*,  $C_{18}H_{14}O_3$ , m. p. 287°, which is transformed into  *$\eta$ -truxillic acid*, m. p. 280°; the presence of benzaldehyde or truxone could not be detected.

[With FARRIS RAY.]—The dry distillation of *trans*-cinnamic acid yields mainly unchanged acid; in addition, styrene, stilbene, and indefinite products are formed. H. W.

**Investigations in the Phenylalanine Series. III. The Hydrogenation of Tyrosine.** E. WASER and E. BRAUCHLI (*Helv. Chim. Acta*, 1923, 6, 199–205).—Weinhagen attempted to hydrogenate tyrosine without success, and, although successful with phenylethylamine prepared from phenylalanine, failed to reduce synthetic phenylethylamine (*A.*, 1918, i, 107). The latter failure was probably due to the presence of some impurity which interfered with the catalytic hydrogenation, since the present authors, working with most carefully purified materials, have successfully hydrogenated tyrosine, using platinum black as the catalyst. Reduction was incomplete in alkaline or neutral solution but went completely in acid solution, best when exactly 2 mols. of hydrochloric acid per mol. of tyrosine was used. *Hexahydrotyrosine* crystallises from hot water in microscopic needles, m. p. 307° (corr., decomp.). It is soluble in about 25 parts of cold water. The hexahydrotyrosine from *l*-tyrosine is dextrorotatory,  $[\alpha]_D^{20} +13.18^\circ$ . The *hydrochloride*, which is extremely soluble in water, crystallises in leaflets or needles, m. p. 249° (decomp.). The *chloroplatinate*,  $(C_9H_{17}O_3N)_2 \cdot H_2PtCl_6 \cdot 3H_2O$ , forms bright yellow needles, m. p. 204° (decomp.). The *picrate* forms yellow needles, m. p. 196° (decomp.);

the *benzoyl* derivative,  $C_{16}H_{21}O_4N$ , forms colourless leaflets, m. p.  $186^\circ$  (corr.). The *phenylhydantoin* from hexahydrotyrosine crystallises in colourless needles, m. p.  $159-161^\circ$  (corr.). E. H. R.

**Investigations in the Phenylalanine Series. IV. The Rotation-Dispersion of Tyrosine and some of its Derivatives.** E. Waser (*Helv. Chim. Acta*, 1923, 6, 206-214).—Although tyrosine itself is levorotatory, most of its known derivatives are dextrorotatory. The rotations of many such derivatives have now been determined for a number of wave-lengths to discover whether any relation exists between the configuration of the asymmetric carbon atom and the rotation-dispersion such as was found by Karrer and Kaase in the glutaric acid series (A., 1919, i, 570). The following table gives the specific rotations at  $15^\circ$  for some of the principal lines:

| Substance.                                    | C 656.3        | 626            | D 589.3        | Hg 546.3       | E 527.0        |
|---|----------------|----------------|----------------|----------------|----------------|
| <i>L</i> -Tyrosine .....                      | $-10.27^\circ$ | $-11.30^\circ$ | $-12.30^\circ$ | $-13.76^\circ$ | $-14.61^\circ$ |
| <i>L</i> -3-Nitrotyrosine .....               | + 1.31         | + 2.36         | + 3.21         | + 3.97         | —              |
| <i>L</i> -3-Aminotyrosine .....               | — 3.69         | — 3.69         | — 3.61         | — 3.54         | —              |
| <i>L</i> -Tyrosine-3-diazonium chloride ..... | + 7.81         | + 9.50         | + 11.87        | —              | —              |
| <i>L</i> -3 : 4-Dihydroxyphenylalanine .....  | $-11.44$       | $-11.80$       | $-12.74$       | $-15.02$       | —              |
| <i>L</i> -3 : 5-Dinitrotyrosine ...           | + 7.81         | + 9.40         | + 11.45        | + 14.30        | + 16.48        |
| <i>L</i> -3 : 5-Diaminotyrosine...            | + 0.00         | + 1.02         | + 2.17         | + 1.18         | —              |
| <i>L</i> -Hexahydrotyrosine.....              | + 10.16        | + 11.83        | + 13.18        | + 15.70        | + 17.16        |

No conclusions of the kind expected are to be drawn from the results. The levorotatory compounds become more strongly *l*-rotatory the shorter the wave-length (tyrosine and 3 : 4-dihydroxyphenylalanine), whilst the *d*-rotatory compounds become more positive. In the cases of the two amino-derivatives there is very little change in rotation for different wave-lengths.

Natural tyrosine can be racemised readily by boiling in sodium hydroxide solution for about three days. *dl*-Tyrosine crystallises in star-shaped aggregates of extremely fine needles. The hydrochloride forms aggregates of long needles with no characteristic melting point. When given to a dog, *dl*-tyrosine is completely transformed and cannot be detected in the urine. E. H. R.

**The Wandering of Acyl Groups in the Cases of Phenolcarboxylic Acids (E. Fischer).** Syntheses of *p*-Di- $\beta$ -resorcylic Acid and *p*-Benzoylpyrogallolcarboxylic Acid. EUGEN PAOSU (*Ber.*, 1923, 56, [B], 407-424).—The cautious hydrolysis of penta-acetyl-*p*-digallic acid by cold, dilute ammonia led unexpectedly to the production of *m*-digallic acid (Fischer, Bergmann, and Lipschitz, A., 1918, i, 172), whereby a migration of the acyl group is involved (cf. A., 1908, i, 893; 1911, i, 875; 1913, i, 479). The constitution of many dipeptides, such as di- $\beta$ -resorcylic acid and gentisic acid, is rendered somewhat uncertain by this observation (cf. Bergmann and Dangschat, A., 1919, i, 273). The structure of *p*-di- $\beta$ -resorcylic acid is now confirmed by its synthesis, and it is established that the migration of aromatic acyl does not

take place with phenolcarboxylic acids of the type of  $\beta$ -resoreylic acid, or, in all probability, of gentisic acid.

It has been assumed previously that the wandering of aromatic acyl groups only takes place in phenolcarboxylic acids which contain the phenolic hydroxyl groups in the vicinal position to one another. As the result of a lengthy series of experiments the author has drawn the conclusion, however, that this view is incorrect and that the phenomenon is due to the influence of the carboxyl group which is most pronounced on the *p*-hydroxyl radicle. This influence is less marked when the carboxyl group is esterified, and is still less pronounced when a phenolic hydroxyl group is in the vicinal position; in the latter case, a migration of the acyl group is not observed.

2:4-Diacetoxybenzoic acid (cf. Bergmann and Dangschat, *loc. cit.*) is prepared by the action of acetic anhydride and pyridine on  $\beta$ -resoreylic acid, and is converted by phosphorus pentachloride in the presence of chloroform or by thionyl chloride into 2:4-di-acetoxybenzoyl chloride, a pale yellow liquid which solidifies when cooled to  $-20^\circ$ , b. p.  $170^\circ/12$  mm. (partial decomp.); the corresponding anilide crystallises in slender, lustrous needles, m. p.  $126-127^\circ$ . The action of 2:4-diacetylbenzoyl chloride and sodium hydroxide on sodium 4-hydroxy-2-acetoxybenzoate in the presence of aqueous acetone leads to the formation of triacetyl-*p*-di- $\beta$ -resoreylic acid,  $C_6H_3(OAc)_2 \cdot CO \cdot O \cdot C_6H_3(OAc) \cdot CO_2H$ , small, ill-defined prisms, m. p.  $151-153^\circ$  after softening at about  $146^\circ$ ; it is hydrolysed by cautious treatment with sodium hydroxide or ammonia to *p*-di- $\beta$ -resoreylic acid, microscopic, prismatic needles, m. p.  $206^\circ$  [ $211^\circ$  corr. (decomp.)], which differs from the corresponding ortho-compound mainly in its relative insolubility in water. It is re-converted by acetic anhydride and pyridine into triacetyl-*p*-di- $\beta$ -resoreylic acid. Short treatment of *p*-di- $\beta$ -resoreylic acid with diazomethane in the presence of ether yields the 4'-methyl ether of methyl *p*-di- $\beta$ -resoreyate,  $OMe \cdot C_6H_3(OH) \cdot CO \cdot O \cdot C_6H_3(OH) \cdot CO_2H$ , slender, lustrous needles, m. p.  $144-145^\circ$ , whereas more protracted treatment in the presence of acetone appears to yield a fully methylated product which has not been examined completely.

4-Benzoyloxy-2-acetoxybenzoic acid (cf. Bergmann and Dangschat, *loc. cit.*) is obtained in 93% yield by the method used in the preparation of triacetyl-*p*-di- $\beta$ -resoreylic acid; it is converted by diazomethane into methyl 4-benzoyloxy-2-acetoxybenzoate, hexagonal prisms, m. p.  $99-100^\circ$ , from which methyl 2:4-dihydroxybenzoate, colourless needles, m. p.  $121-122^\circ$ , is obtained by the action of 5*N*-ammonia.

The derivatives of 2:3:4-trihydroxybenzoic acid have been particularly examined, since migration of the acyl groups is to be expected if Fischer's hypothesis of the influence of vicinal hydroxyl groups is correct; such migrations are not, however, observed. 2:3:4-Triacetoxybenzoic acid, colourless prisms, m. p.  $164^\circ$  after previous softening, is prepared by the action of acetic anhydride and zinc chloride on 2:3:4-trihydroxybenzoic acid and is converted by cautious hydrolysis in an atmosphere of hydrogen into 4-hydroxy-

2:3-diacetoxybenzoic acid, long, colourless needles (+ H<sub>2</sub>O), m. p. (anhydrous) 157° after slight softening; the latter acid appears to be converted by boiling water into 3:4-dihydroxy-2-acetoxybenzoic acid, flat prisms, decomp. 192°. The diacetoxy-acid is transformed by diazomethane into methyl 2:3-diacetoxy-4-methoxybenzoate, rhombic platelets, m. p. 108°, which is hydrolysed to 2:3-dihydroxy-4-methoxybenzoic acid, long, colourless needles, decomp. 207—208°, identical with the substance prepared by Herzig and Pollak (A., 1904, i, 808) by the partial methylation of methyl 2:3:4-trihydroxybenzoate. 4-Hydroxy-2:3-acetoxybenzoic acid and benzoyl chloride yield 4-benzoyloxy-2:3-diacetoxybenzoic acid, aggregates of colourless, slender needles, m. p. 161—162°, which is hydrolysed by 5*N*-hydrochloric acid in the presence of glacial acetic acid to 2:3-dihydroxy-4-benzoyloxybenzoic acid, lustrous leaflets, decomp. 210—211°; re-acetylation of the latter acid with acetic anhydride gives 4-benzoyloxy-2:3-diacetoxybenzoic acid. 2:3-Dihydroxy-4-benzoyloxybenzoic acid is converted by diazomethane into methyl 4-benzoyloxy-2:3-dimethoxybenzoate, coarse, colourless crystals, m. p. 79—80°, from which 4-hydroxy-2:3-dimethoxybenzoic acid, microscopic, colourless, rhombic platelets, m. p. 154—155° after slight previous softening, is obtained by hydrolysis. H. W.

**The Reaction of Alcohols with Bromomethylphthalimide and its Use for the Separation and Identification of Alcohols.**

HARRIS H. HOPKINS (*J. Amer. Chem. Soc.*, 1923, 45, 541—544; cf. Pucher and Johnson, A., 1922, i, 549).—Bromomethylphthalimide reacts with certain alcohols under anhydrous conditions to give crystalline ethers, which can be used for the identification and separation of the alcohols. This procedure may be used for detecting the presence of methyl alcohol in dry acetone. The reaction does not proceed in the presence of moisture, as the bromomethylphthalimide is converted into hydroxymethylphthalimide before it can react with the alcohol. The following ethers are described: *Phthalimidomethyl methyl ether*, C<sub>6</sub>H<sub>4</sub>(CO)<sub>2</sub>N·CH<sub>2</sub>·OMe, m. p. 118°; *phthalimidomethyl ethyl ether*, m. p. 86°; *phthalimidomethyl n-propyl ether*, m. p. 52—53°; *phthalimidomethyl isopropyl ether*, m. p. 92—93°; *phthalimidomethoxyacetic acid ether*, m. p. 185°; *phthalimidomethyl phenyl ether*, m. p. 171—172°; *triphtalimidomethyl glyceryl ether*, m. p. 174—175°. W. G.

**Phenolsulphonophthalein and some of its Derivatives.**

W. R. ORNDORFF and F. W. SHERWOOD (*J. Amer. Chem. Soc.*, 1923, 45, 486—500).—In the preparation of phenolsulphonophthalein from the chloride of *o*-sulphobenzoic acid and phenol, the ordinary method of purification, by solution in sodium hydroxide and subsequent precipitation with acid, does not remove one impurity. This substance is soluble in the alkali hydroxide, but unlike the phthalein it is not soluble in cold aqueous sodium or ammonium hydrogen carbonate. This compound only contains about half as much sulphur as phenolsulphonophthalein, and is apparently

formed from it by the action of the excess of phenol. When the aqueous filtrates from the crude phenolsulphonephthalein were concentrated and then boiled with an excess of pure barium carbonate, *p*-hydroxybenzoylbenzene-*o*-sulphonic acid was obtained as its barium salt. This acid may also be prepared by heating ammonium *o*-sulphobenzoate with phenol for fifteen hours at 180–210°, and is obtained in the form of pink crystals containing 1H<sub>2</sub>O, or as a red, internal anhydride, which probably has the quinonoid structure  $O:C_6H_4:C \begin{smallmatrix} \diagup C_6H_4 \diagdown \\ O \end{smallmatrix} SO_2$ . When heated at

135–140°, this acid loses water and gives phenolsulphonephthalein and the anhydride of *o*-sulphobenzoic acid. The phthalein prepared in this way is free from the impurity mentioned above.

As phenolsulphonephthalein is a coloured compound, it is represented by a quinonoid formula. Because it is the sulphonic acid derivative of benaurin, it is highly probable that dry phenolsulphonephthalein should be represented as an inner oxonium or carbonium salt. The crystallised, air-dried product always contains about 1.26% of water, which indicates that it is a solid solution of this inner salt and the quinonoid hydrate. Phenolsulphonephthalein gives an unstable *diammonium* salt, a *monoammonium*, a *sodium*, and a *disodium* salt. It also gives a *diacetate*, m. p. 165°, and a *dibenzoate*, m. p. 185–186° (decomp.). When heated with aniline for two hours at 140–150°, the phthalein gives *diphenylamine-sulphonephthalein*, a green compound. When pure phenolsulphonephthalein, suspended in water, is boiled with zinc dust, it gives a zinc salt from which, by decomposition with hydrogen sulphide, *dihydroxytriphenylmethanesulphonic acid*,

is obtained. This acid gives a *sodium* salt, and is very readily oxidised in the air to the sulphonephthalein.

When boiled with methyl alcohol containing 3% of hydrochloric acid, phenolsulphonephthalein gives, not an ester, but a colourless *monomethyl ether*, m. p. 178°, which resembles the methyl ether of phenolphthalein very closely in its properties and chemical behaviour. When heated for half an hour in a current of dry air at 170°, the colourless ether is converted into a red *methyl ether*, which, unlike the colourless ether, gives a stable *monoammonium* salt. Under similar conditions, a colourless *ethyl ether*, m. p. 171°, and a coloured *ether*, giving an ammonium salt, were obtained. Phenolsulphonephthalein, its salts, the coloured ethers, and diphenylaminesulphonephthalein are coloured and have the quinonoid structure, but the diacetate, the dibenzoate, and the colourless ethers are derivatives of the lactoid modification.

When tetrabromophenolsulphonephthalein is purified by crystallisation from glacial acetic acid it is colourless and has m. p. 279° (corr.). It has the lactoid, and not the carbinolsulphonic acid structure. Like phenolsulphonephthalein, it is tautomeric and gives coloured quinonoid and colourless lactoid derivatives. Its *hydrate*, its *diammonium*, *disodium*, and *monosodium* salts, and its *methyl ether* are coloured, and have the quinonoid structure. The

*diacetate*, m. p. 234°, and the *dibenzoate* are colourless and are derivatives of the lactoid form. The methyl ether gives an unstable *hydrochloride* and an *ammonium salt*. W. G.

**The Nitration of Benzaldehyde and the Monotropy of *o*-Nitrobenzaldehyde.** OSCAR LISLE BRADY and SAMUEL HARRIS (T., 1923, 123, 484—494).

**Syntheses of Coumarin- and Conifer-aldehydes.** H. PAULY and K. WÄSCHER (*Ber.*, 1923, 56, [B], 603—610).—Hydroxy-phenylacetaldehydes have hitherto been difficultly accessible substances, since their unusual tendency towards resinification under the influence of alkali hydroxide inhibits their preparation by alkaline condensation of hydroxyphenylaldehydes and acetaldehyde. A certain amount of success has been achieved by Tiemann by masking the hydroxyl group by using substances such as glucose, vanillin; it is not possible to use alkali for the removal of the glucose residue, but this can be effected with the aid of emulsin. A more convenient method is now described, which consists in masking the hydroxyl group by transforming it into the methoxymethoxy-residue,  $\text{OMe}\cdot\text{CH}_2\cdot\text{O}-$ ; the latter is ultimately removed by cautious and rapid treatment with very dilute acid.

*o*-Methoxymethoxybenzaldehyde (cf. Höring and Baum, A., 1909, i, 572) condenses with acetaldehyde in aqueous-alcoholic, alkaline solution at 60° to form *o*-methoxymethoxycinnamaldehyde,  $\text{OMe}\cdot\text{CH}_2\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{CH}\cdot\text{CHO}$ , pale yellow crystals, m. p. 55°, b. p. 158—159°/3 mm., the yield being 37% of that theoretically possible. It is converted by short ebullition with acetic acid (50%) containing 0.3% of sulphuric acid into *o*-hydroxycinnamaldehyde, m. p. 133°. Similarly, *p*-methoxymethoxybenzaldehyde, b. p. 132—134°/9 mm. (cf. Höring and Baum, *loc. cit.*) is transformed into *p*-methoxymethoxycinnamaldehyde, a very viscous liquid which could not be caused to solidify, b. p. 158—160°/3 mm., and is converted into *p*-hydroxycinnamaldehyde, pale yellow needles, m. p. 134° (*semicarbazone*, m. p. 224°). 3-Methoxy-2-methoxymethoxybenzaldehyde,  $\text{OMe}\cdot\text{CH}_2\cdot\text{O}\cdot\text{C}_6\text{H}_3(\text{OMe})\cdot\text{CHO}$ , colourless plates, m. p. 56°, b. p. 128—130°/2 mm., is obtained in 11% yield by the action of chloromethyl ether on a suspension of the sodium derivative of *o*-vanillin in toluene. It is converted by acetaldehyde into 3-methoxy-2-methoxymethoxycinnamaldehyde, pale yellow, lustrous platelets, m. p. 91°, which is hydrolysed in the usual manner to 2-hydroxy-3-methoxycinnamaldehyde, pale yellow leaflets, m. p. 131° (*semicarbazone*, almost colourless crystals, m. p. 198° after softening at 195°). 3-Methoxy-4-methoxymethoxybenzaldehyde, colourless needles, m. p. 40°, b. p. 145—149°/4 mm., is transformed in the usual manner into 3-methoxy-4-methoxymethoxycinnamaldehyde, pale yellow needles, m. p. 77—78°, b. p. 165—167°/4 mm., which is further transformed into 4-hydroxy-3-methoxycinnamaldehyde, pale yellow needles, m. p. 82.5° (*semicarbazone*, pale yellow crystals, m. p. 218°); the sodium hydrogen sulphite compound is described. The aldehyde is slowly oxidised to vanillin on exposure to air.

H. W.

**Ring Closures from  $\gamma$ -Aryl-*n*-butyric Acids to Derivatives of 1-Ketotetrahydronaphthalene.** F. KROLLPFEIFFER and W. CHÄFER (*Ber.*, 1923, 56, [B], 620—632).—The conversion of phenyl-*n*-butyryl chloride into 1-ketotetrahydronaphthalene has been described by Kipping and Hill (T., 1899, 75, 146). Since, however, Schroeter (*Chem. Ztg.*, 1920, 759) has succeeded in effecting similar ring closures with the tetrahydronaphthyl-*n*-butyric acids without the employment of a condensing agent, the authors have endeavoured with partial success to avoid the indirect method through the chloride in the case of the simpler phenyl compounds.

The preparation of the requisite  $\gamma$ -aryl-*n*-butyric acids is effected by the condensation of the necessary benzenoid hydrocarbon with succinic anhydride in the presence of aluminium chloride and subsequent reduction of the ketonic acid thus produced by amalgamated zinc and hydrochloric acid; the latter action only gives satisfactory yields if carried out at the atmospheric temperature.

$\gamma$ -Phenyl-*n*-butyric acid is converted by treatment with concentrated sulphuric acid at the temperature of boiling water into 1-keto-1 : 2 : 3 : 4-tetrahydronaphthalene, b. p. 127°/13 mm. (semicarbazone, m. p. 217—220°), the yield being about 50% of that theoretically possible. Similarly,  $\gamma$ -*p*-tolyl-*n*-butyric acid is transformed into 1-keto-7-methyl-1 : 2 : 3 : 4-tetrahydronaphthalene, colourless, crystalline aggregates, m. p. 32·5—33·5°,  $d_4^{25}$  1·0569,  $d_4^{20}$  1·072,  $n_D^{25}$  1·55168,  $n_D^{20}$  1·55674,  $n_D^{25}$  1·57160,  $n_D^{25}$  1·58479,  $n_D^{20}$  1·563. The corresponding semicarbazone crystallises in colourless, slender needles, m. p. 224—225°. The ketone is reduced by amalgamated zinc and concentrated hydrochloric acid to 2-methyl-5 : 6 : 7 : 8-tetrahydronaphthalene, a colourless, mobile liquid, b. p. 224—226°,  $d_4^{25}$  0·9541,  $d_4^{20}$  0·950,  $n_D^{25}$  1·53318,  $n_D^{25}$  1·53719,  $n_D^{25}$  1·54907,  $n_D^{25}$  1·55897,  $n_D^{20}$  1·535 (cf. Schroeter, A., 1921, i, 861). It is converted by bromine in the presence of carbon disulphide into 2-bromo-1-keto-7-methyl-1 : 2 : 3 : 4-tetrahydronaphthalene, slender, colourless needles, m. p. 80·5°, which is transformed by boiling diethylaniline into a mixture of 1-keto-7-methyl-1 : 2 : 3 : 4-tetrahydronaphthalene and 7-methyl- $\alpha$ -naphthol, small, colourless needles, m. p. 109°, b. p. 158—159°/12 mm.

*p*-Ethylbenzoylpropionic acid, m. p. 98—99°, is converted successively into  $\gamma$ -*p*-ethylphenyl-*n*-butyric acid, colourless, lustrous leaflets, m. p. 69—70°, and 1-keto-7-ethyl-1 : 2 : 3 : 4-tetrahydronaphthalene, a colourless liquid, b. p. 152—153°/12 mm.,  $d_4^{22}$  1·0556,  $d_4^{20}$  1·053,  $n_D^{22}$  1·55478,  $n_D^{22}$  1·55988,  $n_D^{22}$  1·57454,  $n_D^{22}$  1·58752,  $n_D^{20}$  1·559 (semicarbazone, colourless needles, m. p. 223—225°). 2-Ethyl-5 : 6 : 7 : 8-tetrahydronaphthalene has b. p. 245—246°,  $d_4^{26}$  0·9499,  $d_4^{20}$  0·948,  $n_D^{26}$  1·53072,  $n_D^{26}$  1·53474,  $n_D^{26}$  1·54627,  $n_D^{26}$  1·55594,  $n_D^{20}$  1·534.

6 : 2 : 4-Dimethylbenzoylpropionic acid, m. p. 111—112°, yields  $\gamma$ -*m*-xyl-*n*-butyric acid, m. p. 71°, which is converted by concentrated sulphuric acid in poor yield into 1-keto-5 : 7-dimethyl-1 : 2 : 3 : 4-tetrahydronaphthalene, coarse prisms, m. p. 49—50°.

$d_4^{25}$  1.0654,  $d_4^{20}$  1.061,  $n_D^{15}$  1.55986,  $n_D^{15}$  1.56496,  $n_D^{15}$  1.57971,  $n_D^{15}$  1.59284,  $n_D^{20}$  1.563 (*semicarbazone*, slender, colourless needles, m. p. 234—235°). (The poor yield is due to the sulphonation of the acid; the sodium salt of sulpho-*m*-xylyl-*n*-butyric acid is described.) The ketone is more conveniently prepared from  $\gamma$ -*m*-xylyl-*n*-butyryl chloride either by the action of heat or, more rapidly, by means of aluminium chloride in the presence of light petroleum. It is reduced by amalgamated zinc and hydrochloric acid to 5:7-dimethyl-1:2:3:4-tetrahydronaphthalene, a colourless liquid, b. p. 250—252°/atmospheric pressure,  $d_4^{20}$  0.960,  $d_4^{21}$  0.9589,  $n_D^{21}$  1.53683,  $n_D^{21}$  1.54094,  $n_D^{21}$  1.55287,  $n_D^{21}$  1.56297,  $n_D^{20}$  1.541.

1:2:3:4-Tetrahydronaphthalene and succinic anhydride yield  $\beta$ -2-tetrahydronaphthoylpropionic acid, m. p. 121—122°, which is converted into  $\gamma$ -tetrahydronaphthyl-*n*-butyric acid, colourless crystals, m. p. 49—50°. The latter substance is transformed by concentrated sulphuric acid into 1-keto-octahydroanthracene, m. p. 46—47°, b. p. 202°/13 mm. (*semicarbazone*, m. p. 252—253°). 2-Bromo-1-keto-octahydroanthracene crystallises in colourless needles, m. p. 110°; it is converted by boiling diethylaniline into 1-keto-octahydroanthracene and 1-hydroxy-5:6:7:8-tetrahydroanthracene, a colourless powder, m. p. 124°, which becomes brown on exposure to air.

The condensation of naphthalene with succinic anhydride leads to the formation of a difficultly separable mixture of  $\beta$ -1- and -2-naphthoylpropionic acids.  $\beta$ -1-Naphthoylpropionic acid, m. p. 131—132°, is prepared by the action of heat on  $\alpha$ -naphthoyliso-succinic acid, decomp. 158°, which is obtained by condensing ethyl sodiomalonate with  $\alpha$ -naphthyl bromomethyl ketone in the presence of benzene and subsequent hydrolysis of the product. Attempts to effect ring closure with mixtures of  $\gamma$ -1- and -2-naphthyl-*n*-butyric acids did not lead to any decisive result (cf. Schäfer, *Diss.*, Marburg, 1922).

$\beta$ -*p*-Methoxybenzoylpropionic acid, m. p. 147—148°, is reduced to  $\gamma$ -*p*-methoxyphenyl-*n*-butyric acid, colourless leaflets, m. p. 59—60°. The latter acid is readily sulphonated by sulphuric acid, so that this reagent cannot be used for converting it into 7-methoxy-1-keto-1:2:3:4-tetrahydronaphthalene, which, however, is prepared by the action of heat or of aluminium chloride in the presence of light petroleum on  $\gamma$ -*p*-methoxyphenyl-*n*-butyryl chloride; it crystallises in colourless platelets, m. p. 60—61° (*semicarbazone*, m. p. 222—224° when rapidly heated).

$\beta$ -Benzoyl- $\alpha$ -methylpropionic acid,  $\text{CH}_3\text{Bz}\cdot\text{CHMe}\cdot\text{CO}_2\text{H}$ , colourless needles, m. p. 129—140°, is converted into  $\gamma$ -phenyl- $\alpha$ -methyl-*n*-butyric acid, b. p. 174°/15 mm. (*anilide*, slender, colourless prisms, m. p. 140°). Concentrated sulphuric acid transforms the latter acid into 1-keto-2-methyl-1:2:3:4-tetrahydronaphthalene, a colourless liquid, b. p. 132°/15 mm.,  $d_4^{20}$  1.0600,  $d_4^{20}$  1.061,  $n_D^{20}$  1.54669,  $n_D^{20}$  1.55154,  $n_D^{20}$  1.56542,  $n_D^{20}$  1.57764,  $n_D^{20}$  1.552; the *semicarbazone* crystallises in colourless leaflets, m. p. 199—201° when rapidly heated.

H. W.

**Halogenation. XXII. The Action of Bromine and Nitric Acid on Organic Compounds. Preparation of Nitrosyl Tribromide and the Formation of Tetrabromobenzoquinone.**

RASIK LAL DATTA and NIHAR RANJAN CHATTERJEE (*J. Amer. Chem. Soc.*, 1923, 45, 480—482).—It has previously been shown (*A.*, 1916, i, 705) that chloropicrin and tetrachloro-*p*-benzoquinone are formed by the exhaustive action of aqua regia on organic compounds. It has now been found that bromine and nitric acid behave similarly on organic compounds, giving rise to tetrabromobenzoquinone and a mixture of bromonitro-derivatives of methane. A mixture of hydrobromic and nitric acids gives the same results, but in this case nitrosyl tribromide is formed in the first instance.

W. G.

**$\beta$ -Halogen-substituted Anthraquinone Compounds.** F. W. ATACK (U.S. Pat. 1434980).— $\alpha$ -Halogenanthraquinone derivatives are converted into the corresponding  $\beta$ -derivatives when heated at 200° (or lower for a longer period) with concentrated sulphuric acid; chlorination may be effected simultaneously in presence of a chlorine carrier, such as iodine, if necessary. Generally,  $\beta$ -bromo-derivatives can be produced from  $\alpha$ -bromo-derivatives, even in the presence of other substituents, such as sulpho-groups, and of aminogroups if in a different nucleus from the bromine.

CHEMICAL ABSTRACTS.

**The Stereoisomeric Forms of Menthone.** REGINALD SLATER LUGHESDON, HENRY GEORGE SMITH, and JOHN READ (*Proc. Roy. Soc. New South Wales*, 1922, 56, 170—175).—Four optically active menthones are theoretically capable of existence, and they may be respectively represented by the symbols *Dd*, *Ll*; *Ld* and *Dl*, where *d* and *l* indicate the optical effects of the 1-carbon atom and *D* and *L* are similarly used for the 4-carbon atom. Reasons are given for regarding the *l*-menthone obtained by the oxidation of natural *l*-menthol as having the *Ld* configuration, and the *d*- and *l*-isomenthones as being the *Dd* and *Ll* compounds, respectively. The optical effects of the two asymmetric carbon atoms would thus be opposed in the menthones and conjoined in the isomenthones. The catalytic hydrogenation of *dl*-, *d*-, and *l*-piperitones gave an inactive isomenthone, forming a sparingly soluble semicarbazone, m. p. 219—220°, and two highly active isomenthones having  $[\alpha]_D^{20} +58.33^\circ$  and  $-57.40^\circ$ , respectively. It is suggested that these substances belong to a type of partly racemic compounds, of which four are theoretically possible, namely, *Dd*, *Dl*; and *Ld*, *Ll*, representing 1-racemic isomenthones, and *Dd*, *Ld*; and *Dl*, *Ll*, representing 4-racemic isomenthones. Finally, two wholly racemic compounds are to be expected, *Dd*, *Ll*; and *Ld*, *Dl*, being *l*-menthone, and *i*-isomenthone, respectively.

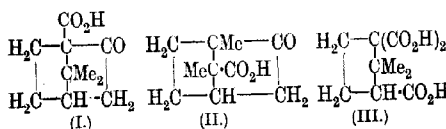

G. F. M.

**Two Definite Compounds of Nitrogen Peroxide and Camphor.** PAUL PASCAL and GARNIER (*Compt. rend.*, 1923, 176, 50—452).—A thermal analysis of the binary mixture, nitrogen

peroxide and camphor, shows the existence of two definite compounds, namely,  $5\text{N}_2\text{O}_4 \cdot 4\text{C}_{10}\text{H}_{16}\text{O}$ , m. p.  $-52^\circ$ , and  $2\text{N}_2\text{O}_4 \cdot 3\text{C}_{10}\text{H}_{16}\text{O}$ , m. p.  $-45.5^\circ$ . The former gives with nitrogen peroxide a series of solid solutions containing a maximum of 27% of camphor at  $-60^\circ$ . The binary system gives three eutectic mixtures, namely, a mixture, m. p.  $-60^\circ$ , containing 60.5% of nitrogen peroxide, a mixture, m. p.  $-55.5^\circ$ , containing 34.5% of nitrogen peroxide, and a mixture, m. p.  $-46.5^\circ$ , containing 26% of nitrogen peroxide.

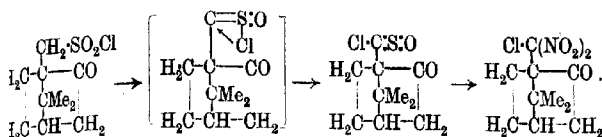

W. G.

**Transformation of *d*- and *l*-Camphorsulphonyl Chlorides into 10-*d*- and -*l*-Chlorosulphoxidocamphor.** The Constitution of Ketopinic Acid and of Reyckler's Camphorsulphonic Acid. E. WEDEKIND, D. SCHENK, and R. STRÜSSER (*Ber.*, 1923, 56, [B], 633—649).—It has been shown previously (Wedekind and Schenk, A., 1911, i, 190) that the action of strong tertiary bases on simple aromatic sulphonyl chlorides does not lead to the isolation of the expected "sulphens,"  $\text{CHAr} \cdot \text{SO}_2$ , which, however, are possibly formed as unstable intermediate products which break down into stilbenes and sulphur dioxide. In the hope of isolating such sulphens or derived substances containing sulphur, an examination has been made of more complex sulphonyl chlorides, for which purpose Reyckler's *d*-camphorsulphonyl chloride has been selected. The substance reacts readily with triethylamine (or pyridine), giving a mixture of equimolecular amounts of *d*-chlorosulphoxidocamphor,  $\text{C}_{10}\text{H}_{13}\text{O}_2\text{SCl}$ , and triethylammonium *d*-camphorsulphonate. The constitution of the former compound is mainly deduced from a study of its action on boiling dilute nitric acid, with which it yields sulphuric acid, a chlorodinitrocamphor (thus showing that the camphor skeleton is preserved practically unchanged in chlorosulphoxidocamphor and that the chlorine is united to a carbon atom), and *d*-ketopinic acid. *r*-Ketopinic acid has been obtained by Gilles and Renwick (T., 1897, 69, 1397, 1402) by oxidising pinene hydrochloride with fuming nitric acid, but its constitution has not previously been elucidated. Its

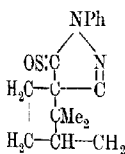

mode of formation renders one of the annexed formulae (I or II) possible, and the choice in

favour of I is rendered possible by the observation that it is oxidised to a tricarboxylic acid [carboxyapocamphoric acid (formula III)], which loses carbon dioxide when heated and yields apocamphoric acid. Since ketopinic acid is derived from camphor solely by alteration of the groups attached to the carbon atom 10, it follows that the substituents in chlorosulphoxidocamphor must also be present in this position, and the reaction may therefore be shown by the scheme:

Reychler's camphorsulphonic acid was regarded by the discoverer as an  $\alpha$ -compound, whereas subsequently Armstrong and Lowry (T., 1902, 81, 1469) brought forward evidence to show that the sulphonic acid group is attached to carbon atom 6 or 10, preference being finally accorded to the first possibility. The relationship of camphorsulphonyl chloride to ketopinic acid places beyond doubt the attachment of the acid residue to carbon atom 10, and this conception is in excellent agreement with the observed ability of camphorsulphonamide to yield an internal anhydride, since it indicates the production of a heterocyclic five-membered ring.

*d*-Camphorsulphonyl chloride reacts very energetically with triethylamine or pyridine, giving *d*-chlorosulphoxidocamphor, pale yellow, prismatic needles, m. p. 85°,  $[\alpha]_D^{25} + 58.28^\circ$  in benzene,  $[\alpha]_D^{25} + 136.2^\circ$  in chloroform. *l*-Chlorosulphoxidocamphor, prepared in a similar manner, has  $[\alpha]_D^{25} - 58.40^\circ$  in benzene and  $[\alpha]_D^{25} - 136.2^\circ$  in chloroform. *r*-Chlorosulphoxidocamphor is prepared by mixing equal quantities of its optically active components; it has m. p. 103.5°, and is shown to be a true racemate. The chlorine atom in these compounds is relatively firmly attached, and is not removed by silver oxide or by boiling aqueous silver nitrate solution. The protracted action of steam leads to the production of hydrogen chloride, sulphur dioxide, and sulphur, the latter being also prepared by the action of methyl-alcoholic ammonia. Reduction with stannous chloride gives an uncrystallisable substance containing sulphur.

It is remarkable that the chlorine atom is very readily removed by the action of phenylhydrazine, with the production of phenylhydrazine hydrochloride, a substance which the author terms *norcamphorylsulphoxide-N-phenylpyrazolone* (annexed formula), decomp. 155° after forming a clear, reddish-brown resin at about 80°. Chlorosulphoxidocamphor reacts with semicarbazide to give a chlorine-free product, m. p. 165–167° (decomp.), which could not be caused to crystallise.

The oxidation of the 10-chlorosulphoxidocamphors with nitric acid leads to the optically active 10-chloro-10:10-dinitrocamphors, m. p. 150.5° (decomp.),  $[\alpha]_D^{25}$  for which is respectively  $+52.06^\circ$  and  $-52.13^\circ$  in benzene and  $+55.47^\circ$  and  $-55.40^\circ$  in chloroform. The optically active *ketopinic acids* are simultaneously produced; they can also be obtained by the oxidation of the chlorosulphoxidocamphors with potassium permanganate or by the hydrolysis of the active 10-chloro-10:10-dinitrocamphors with water or, preferably, with water and calcium carbonate or slaked lime. *d*-Ketopinic acid has m. p. 234°,  $[\alpha]_D^{25} + 28.02^\circ$  in benzene, whereas the

constants of the *L*-isomeride are m. p.  $234^{\circ}$ ,  $[\alpha]_D^{25} - 27.67^{\circ}$  in benzene; *r*-ketopinic acid has m. p.  $234^{\circ}$ . The active ketopinic acids are converted into the corresponding *phenylhydrazones*, m. p.  $150.5^{\circ}$ , by the union of equal quantities of the antipodes, of which *r*-ketopinic acid phenylhydrazone, m. p.  $126.5^{\circ}$ , is prepared; this is identical with the product obtained from *r*-ketopinic acid derived from pinene hydrochloride [the m. p.  $146^{\circ}$  recorded for the inactive phenylhydrazone by Gilles and Renwick (*loc. cit.*) appears to be erroneous].

The chlorodinitrocampors are reduced by stannous chloride and hydrogen chloride in the presence of glacial acetic acid to the corresponding *ketopinonitriles*, m. p.  $197-198^{\circ}$ ,  $[\alpha]_D^{25} + 26.45^{\circ}$  and  $[\alpha]_D^{25} - 26.10^{\circ}$ , respectively, when dissolved in chloroform. Reduction appears to proceed along the lines indicated by the schemes  $R\cdot CCl(NO_2)_2 \rightarrow R\cdot C(NH_2)NOH + HCl, NH_2\cdot OH \rightarrow R\cdot CN$  and  $R\cdot CCl(NO_2)_2 \rightarrow R\cdot CCl(NH_2)_2 + HCl, NH_3 \rightarrow R\cdot CN$ , since both ammonia and hydroxylamine are also formed. The nitriles are hydrolysed by boiling sulphuric acid (50%) to the ketopinic acids, m. p.  $234^{\circ}$ .  
H. W.

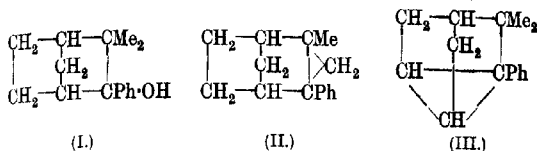

**Optically Active Heavy Metal Complexes.** I. LEFSCHITZ (*Rec. trav. chim.*, 1922, 41, 627-636).—Complex heavy metal salts and co-ordination compounds of hydroxymethylenecamphor are described. Earlier measurements of the rotatory dispersion of, for instance, aqueous solutions of tartaric acid in the presence of alkali and the salt of a heavy metal are open to the objection that such solutions may contain several optically active complexes, and that the observed experimental figures may be due to the superposition of the effects of their various components. The ferric, acid copper, normal copper, nickel, uranyl, aluminium, chromic, cobaltic, carbonatotetrammine and diethylenediamine-carbonato salts of hydroxymethylenecamphor are described. These compounds are soluble in organic media, so that the above objection presumably does not apply. The salts are all well-defined compounds with high rotatory powers, and, with the exception of the aluminium salt, all are brightly coloured. The rotatory dispersion of these compounds has been measured in the neighbourhood of their absorption bands, and has been found to be normal in some cases and anomalous in others. With the exception of the normal copper salt, however, none of these compounds exhibits the Cotton effect in the visible region of the spectrum, in spite of the fact that they all show characteristic selective absorption. The chromic salt is noteworthy in that its solutions in organic liquids exhibit strong dichroism and its rotatory dispersion curve shows both a maximum and a minimum in the visible region of the spectrum.

Similar ferric, chromic, and cobaltous derivatives of nitrocamphor are described.  
H. E.

***tert*-Phenylcamphenilol, its Conversion into Phenyl-pericycloapocamphane and Transformation into Phenylapocamphor.** MARIA BREDT-SAVELSBERG (*Ber.*, 1923, 56, [B], 554-561).—*tert*-Phenylcamphenilol has been prepared and its dehydration investigated since the process appeared to be of con-

siderable interest owing to the accompanying, enforced change of the carbon skeleton.

[With FRANZ TOUSSAINT.]—*tert*-Phenylcamphenilol (formula I), a colourless, viscous liquid, b. p. 122°/4 mm., 160–166°/13 mm.,

about 276°/atmospheric pressure (slight decomp.),  $d_4^{14}$  1.0717,  $n_D^{14}$  1.55518, is obtained by the action of magnesium phenyl bromide on camphenilone in the presence of ether (the corresponding optically active compound has  $[\alpha]_D +11.2^\circ$ ). It is a remarkably stable substance which is only slowly attacked by metallic sodium. It does not appear to yield a crystalline phenylurethane. The action of thionyl chloride or phosphorus pentachloride on it yields a mixture of the chloride and the hydrocarbon formed from the latter by loss of hydrogen chloride; treatment of the crude product with sodium phenoxide (or prolonged heating of *tert*-phenylcamphenilol with acetic anhydride at 170–180°) yields *phenyl- $\alpha$ -pericycloapocamphane*, a colourless, mobile liquid, b. p. 96–97°/5 mm.,  $d_4^{25}$  1.00609,  $n_D^{25}$  1.54710, which is stable towards permanganate. Its mode of formation renders possible the alternative formulæ II and III, of which the latter is preferred mainly on account of the observation that the inactive hydrocarbon is obtained from the optically active tertiary alcohol, whereas a substance of the constitution II is asymmetric, and would probably therefore be optically active.

Phenyl- $\alpha$ -pericycloapocamphane is converted by glacial acetic acid in the presence of a little concentrated sulphuric acid at 60–65° into *phenylapoisobornyl acetate*, b. p. 142–143°/4 mm.,  $d_4^{20}$  1.06888,  $n_D^{20}$  1.53003, and by anhydrous formic acid at 70° into *phenylapoisobornyl formate*, b. p. 127–128°/2 mm. The esters are hydrolysed with some difficulty to *phenylapoisoborneol* (annexed formula), a liquid, b. p. 145°,  $d_4^{12}$  1.0666,  $n_D^{12}$  1.55518. The latter substance is oxidised by chromic acid in glacial acetic acid solution to *phenylapocamphor*, b. p. 143°/55 mm.  $\text{CH}_2\text{CPh} \cdot \text{CO}_2\text{H}$  (semicarbazone, decomp. 199°) and by potassium permanganate in alkaline solution to *phenylapocamphoric acid* (annexed formula), decomp. 206°, which is transformed when distilled into the corresponding *anhydride*, m. p. 208–209°.

H. W.

Chemistry of the Phellandrenes. ERIC HURST, HENRY GEORGE SMITH, and JOHN READ (*Proc. Roy. Soc. New South Wales*, 1922, 56, 176–179).—*l*- $\alpha$ -Phellandrene gives as already recorded by Wallach and by Schreiner a mixture of two nitrosites, of which

the less soluble, or  $\alpha$ -nitrosite, was found to melt at 120–121°, agreeing with the figure given by Schreiner, but somewhat higher than that given by Wallach. Solutions of *l*- $\alpha$ -phellandrene  $\alpha$ -nitrosite in chloroform and in other organic solvents exhibited pronounced mutarotation, leading in every case to optical inversion in course of time. This observation has an important bearing on the discrepancy between the values for  $[\alpha]_D$  given by the above-mentioned authors, and on the application of the nitrosite reaction for the diagnosis of phellandrenes in essential oils. The initial value found for  $[\alpha]_D^{20}$  in freshly prepared chloroform solution was +137.7°. The  $\beta$ -nitrosite of *l*- $\alpha$ -phellandrene also appears to exhibit somewhat similar changes. G. F. M.

#### Australian *Melaleucas* and their Essential Oils. VI.

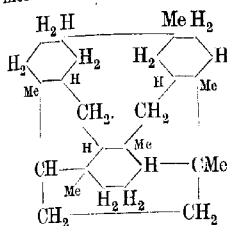

R. T. BAKER and H. G. SMITH (*Proc. Roy. Soc. New South Wales*, 1922, 56, 115–124).—The oil of *Melaleuca ericifolia* has the following constants:  $d^{15}_4$  0.8938,  $\alpha_D +13.3$ ,  $n^{20}_D$  1.4705. Between 168° and 190°, 52% distilled, consisting principally of *d*-pinene, *d*-limonene and dipentene, together with some cineol and terpineol; 26% distilled between 190° and 215°, consisting largely of terpineol. The remainder, about 15%, was mainly a sesquiterpene. The cineol was less than 10% of the total oil, and the oil cannot therefore replace the cajuput oil of commerce, which should contain at least 50% of cineol, and much less terpenes. The chief oxygenated constituent is terpineol, which imparts a more aromatic odour to the oil than that of cajuput oil. The oil of *M. Deanei* was only obtained in 0.7% yield from the leaves of the plant, and it was found to consist largely of *d*-pinene, together with about 15% of cineol and 4% of a high boiling alcohol, probably terpineol. The oil had the following characters:  $d^{15}_4$  0.8888,  $\alpha_D +22.7$ , and  $n^{20}_D$  1.4646. It has no economic value. G. F. M.

**The Occurrence of *l*-Phellandrene in the Oil of *Melaleuca acuminata*.** HENRY G. SMITH (*Proc. Roy. Soc. New South Wales*, 1922, 56, 159–161).—The oil of *Melaleuca acuminata* has the following characters:  $d^{15}_4$  0.8935,  $\alpha_D -12.8$ ,  $n^{20}_D$  1.4690, acid value 1.1, saponification value 4.5, saponification value after esterification 21.2, cineol content 43.7%. Thirty per cent. distilled between 165° and 170°, and 62% between 170° and 190°. After separation of the cineol as phosphate, the residual terpenes distilled to the extent of 80% between 166° and 172°. The chief constituent was apparently *l*-phellandrene, which was identified by its nitrosite. It is probable that this *l*-phellandrene will be found not to be identical with the *l*-phellandrene occurring in the oils of species of the "peppermint group" of eucalypts. G. F. M.

**The Constituents of Indian Turpentine from *Pinus longifolia*, Roxb.** II. JOHN LIONEL SIMONSEN and MADYAR GOPAL RAU (*T.*, 1923, 123, 549–560).

**Composition of Caoutchouc.** MAITLAND C. BOSWELL [with A. HAMBLETON, R. R. PARKER, and R. R. McLAUGHLIN] (*Trans. Roy. Soc. Canada*, 1922, 16, III, 27–47).—The reactions used in

the investigation of the constitution of caoutchouc have been too drastic, and have given misleading indications of a fairly simple molecule. The earlier work is reviewed and certain new derivatives

are described. On the result of these researches a new formula (appended) is suggested which, it is claimed, adequately expresses the whole of the facts. Oxidation of caoutchouc dissolved in carbon tetrachloride by aqueous hydrogen peroxide yields a white, gummy mass,  $C_{30}H_{48}O_8$ , which readily undergoes atmospheric oxidation to a compound,  $C_{25}H_{40}O_2$ ; this compound can also be obtained by

the atmospheric oxidation of the pasty compound,  $C_{25}H_{40}O$  which is produced by the action of cold aqueous potassium permanganate on a solution of deresinised caoutchouc in carbon tetrachloride. Another compound isolated from the hydrogen peroxide reaction product had the composition  $C_{16}H_{24}O$ . By the action of iodine and aqueous hydrogen peroxide on caoutchouc dissolved in carbon tetrachloride a compound,  $C_{23}H_{40}O_8I$ , was obtained. Atmospheric oxidation of thinly sheeted deresinised caoutchouc in sunlight gave a tough, rubbery substance,  $C_{10}H_{16}O$ , and a brittle, transparent mass,  $C_{25}H_{40}O_2$ , which were separable by making use of the solubility of the former in carbon disulphide. Structural formulæ are given showing the relationship of these products with the parent caoutchouc (see also *J.S.C.I.*, 1923, 42, 63A).

D. F. T.

**Amber.** A. TSCHIRCH, E. AWENG, C. DE JONG, and E. S. HERMANN (*Helv. Chim. Acta*, 1923, 6, 214—225; cf. Tschirch and Aweng, A., 1895, i, 384).—A chemical comparison has been made of the two forms of amber, succinite and gedanite. The material was extracted with alcohol, the soluble portion again extracted with light petroleum, and the insoluble portion dissolved in ether. By extracting the ethereal solution with ammonium carbonate solution, two *succinoxyabietic acids* were obtained, that from succinite having the composition  $C_{20}H_{30}O_4$ , m. p. 122°, and that from gedanite,  $C_{19}H_{28}O_4$ , m. p. 120°. It is suggested that these may be homologues; they are present to the extent of about 0.5% in the amber. They are monobasic acids. By extracting the above ethereal solution next with sodium carbonate solution there was obtained a solution of *succinoabietinolic acid*,  $C_{40}H_{60}O_5$ , the composition being the same from both forms of amber. This also is a monobasic acid, and is present to the extent of 12%. These acids may be formed by autoxidation of resinic acids of the type of abietic acid,  $C_{20}H_{30}O_2$ . When the extract soluble in light petroleum is treated with 5% sodium hydroxide solution, a residue is left which after purification has the composition  $C_{40}H_{60}O_2$  and is termed *succinoabietinol*; it is present to the extent of 6%. Distillation of the alkaline solution with steam yielded about 0.2% of *d*-borneol, and from the alkaline solution addition of acid precipitates a new

monobasic acid, *succinosilvinic acid*,  $C_{22}H_{36}O_2$ , m. p.  $104^\circ$ , present to the extent of about 4%. The portion of amber insoluble in alcohol when hydrolysed with alkali gives succinic acid, about 2%, and a *succinoresinol*,  $C_{17}H_{20}O$ , about 3% on the original amber. The latter is undoubtedly the alcohol with which the succinic acid is combined. The trace of sulphur which is present in succinite but not in gedanite is associated with the succinoresinol. The remainder of the portion of the amber insoluble in alcohol, the *succinoresen*, which forms 65% of the whole in both succinite and gedanite, has m. p.  $324^\circ$ , and is quite indifferent to alkalis. It has the composition  $C_{22}H_{36}O_2$  and by distillation in a vacuum gives a mixture of phenols and terpenes. The possibility of the formation of the above constituents of amber from the resinic acids such as abietic acid found in recent conifer resins is discussed.

E. H. R.

**Studies of the Glucosides. II. Arbutin.** ALEXANDER KILLEN MACBETH and JOHN MACKAY (T., 1923, 123, 717—724).

**Tannins. II. Chinese Tannin.** P. KARRER, HARRY R. SALOMON, and J. PEYER (*Helv. Chim. Acta*, 1923, 6, 3—36).—E. Fischer considered Chinese tannin to be practically identical with penta-*m*-digalloyl-glucose (A., 1919, i, 87, 278). It is now shown, however, that the tannin is not a uniform substance, but can be separated by a suitable process into fractions differing considerably in rotatory power. The fractionation was accomplished by precipitating an aqueous solution of the tannin with aluminium hydroxide. The latter first dissolves in the tannin solution, but after a short time a precipitate appears, a compound of tannin and alumina, the nature of which is not yet understood. The compound was decomposed with acid in the cold, and the tannin extracted with ethyl acetate. The tannin first precipitated had the lowest rotatory power, the last had the highest. After a series of about eighty fractionations, the extreme fractions had rotations of  $+30^\circ$  and  $+157^\circ$ , respectively, in water, and  $+40.6^\circ$  and  $+51.5^\circ$  in pyridine. Similar results were obtained with different commercial samples of tannin and with samples extracted from the galls with acetone.

When the fractions having  $[\alpha]_D +80^\circ$  and above were treated with glacial acetic acid and hydrogen bromide at the ordinary temperature, they gave a 1-bromotetra(1-galloyl)glucose, a substance difficult to purify, which was readily converted by acetyl bromide into 1-bromotetra(triacetyl(1-galloyl)-glucose,  $C_{38}H_{51}O_{34}Br$ , an amorphous substance,  $[\alpha]_D +59.5^\circ$  in acetone. This was identical with a substance obtained in an exactly similar manner from synthetic penta(triacetyl(1-galloyl)-glucose, this product having  $[\alpha]_D +58.83^\circ$ . When warmed with sodium acetate and acetic anhydride, the above compound gave tetra(triacetyl(1-galloyl)-1-acetylglucose,  $C_{34}H_{42}O_{15}(OAc)_4$ . This is a white, amorphous substance; the specimen from the high rotating tannin fraction had  $[\alpha]_D +44.3^\circ$  in acetone, sinters from  $110^\circ$ , m. p.  $130$ — $135^\circ$ ; the sample from synthetic penta(triacetyl(1-galloyl)-glucose had  $[\alpha]_D +44.6^\circ$  and a

similar m. p. When treated with methyl alcohol and silver carbonate, bromo-1-tetra(triacetylgalloyl)-glucose gave tetra(triacetylgalloyl)- $\beta$ -methylglucoside,  $C_{55}H_{61}O_{33} \cdot OMe$ ,  $[\alpha]_D +31.8^\circ$  in acetone (from tannin) and  $+31.5^\circ$  (synthetic). Further, this methylglucoside was proved identical with that prepared from  $\beta$ -methylglucoside and triacetylgalloyl chloride, which had  $[\alpha]_D +32.9^\circ$ . On the other hand, tetra(triacetylgalloyl)- $\alpha$ -methylglucoside from  $\alpha$ -methylglucoside and triacetylgalloyl chloride had  $[\alpha]_D +42.3^\circ$  in acetone.

The above observations establish conclusively that the higher rotating fractions of Chinese tannin are derived from a penta-galloylglucose. The variations among the higher rotating fractions must be due to variations in the number and disposition of the depsidic galloyl groups present as digalloyl residues. The yield of tetra(triacetylgalloyl)-1-acetylglucose from any particular tannin fraction may be regarded as practically quantitative; hence the weight of this compound obtained gives a quantitative estimate of the number of gallic acid residues originally present. The mean number found for the different fractions was between 8 and 9 gallic acid residues per mol. of dextrose. Probably the different fractions contain from octa- to deca-galloylglucoses.

The lower rotating tannin fractions gave 1-bromotetra(triacetylgalloyl)-glucose and other derivatives differing markedly in rotatory power from those derivatives obtained from penta(triacetylgalloyl)-glucose. These fractions probably contain impurities besides the higher galloylated glucoses. It is concluded that Chinese tannin is a mixture of closely related galloylated glucoses, and that this complexity is the cause of its colloidal character. The pure substances must be very sparingly soluble in water, but the mixture forms colloidal supersaturated solutions. The living organism here makes use, as in the case of albumin, of the property possessed by insoluble substances of forming colloidal solutions in admixture with other substances of closely related structure.

E. H. R.

**Structure and Formation of Humic Acids and Coal.** J. MARCUSSE (Z. angew. Chem., 1923, 36, 42—43; cf. A., 1921, ii, 590; 1922, i, 437).—The absence of furan derivatives from, and the presence of benzene derivatives among, the products of the oxidation under pressure of humic acids furnishes no evidence whatever for the absence of furan nuclei in these substances, or for a benzene structure, since in the first place furan derivatives would not remain undecomposed under the conditions of the oxidation, and, secondly, benzene derivatives are obtained under similar conditions from cellulose and similar substances which certainly do not themselves possess a benzene structure. Eller's synthesis of humic acids by the oxidation of phenols with permanganate likewise furnishes no proof of a hydroxyquinonoid structure, since the boiling nitric acid used to obtain the nitro-compound, which was similar to the nitro-derivatives of the humic acids, would have oxidised the quinone nuclei, just as benzo-

quinone is converted by oxidising agencies into maleic acid, of which the anhydride is actually a furan derivative. The formation of chloranil by the oxidation of humic acids with potassium chlorate and hydrochloric acid can equally well have originated from a difuran derivative. With regard to the formation of coal, the humic acids originating from wood are converted by loss of carbon dioxide and water into pyrohumic acid and pyrohumic ketone, which, together with bitumen, cellulose, lignin, and mineral matter form brown coal. This is then converted by heat and pressure into ordinary coal and anthracite, and the synthetic production can be carried out by heating brown coal in a light mineral oil at 300° for twelve hours in a closed tube. The product is black, and shows all the properties of coal, being, unlike the original material, insoluble in molten alkali hydroxide, and giving no lignin reaction with dilute nitric acid. The synthetic coal differed from the natural product only in the absence of the asphaltic substances, the carboides, which are formed in nature from the waxy constituents of brown coal, and to which the lustre of the coal is due.

G. F. M.

#### Benzopyronesulphonic Acids and Coumarinmercaptans.

MARGARETE KRÜGER (*Ber.*, 1923, 56, [B], 480—488).—4:7-Dimethylcoumarin-6-sulphonic acid, colourless, slender needles, m. p. above 285° after previous darkening, is obtained by the addition of 4:7-dimethylcoumarin to sulphuric acid containing 20% of sulphur trioxide at 0° and heating the mixture at 80° after solution has become complete at the atmospheric temperature; the *sodium*, *potassium*, and *ammonium* salts are described. The dry sodium salt is transformed by phosphorus pentachloride at 160—170° into 4:7-dimethylcoumarin-6-sulphonyl chloride, large, colourless prisms, m. p. 175°, which is converted by ethyl alcohol into ethyl 4:7-dimethylcoumarin-6-sulphonate, lustrous needles, m. p. 172°. The sulphonyl chloride is reduced by zinc dust in the presence of alcohol to 4:7-dimethylcoumarin-6-thiol, small needles, m. p. 255°, the *mercury* and *lead* derivatives of which are described.

In a similar manner, 4-methylcoumarin-6-sulphonic acid (cf. Harnisch, *Diss.*, Berlin, 1911) is transformed into 4-methylcoumarin-6-sulphonyl chloride, pale yellow rhombs, m. p. 137°, ethyl 4-methylcoumarin-6-sulphonate, colourless, lustrous needles, m. p. 151—152°, and 4-methylcoumarin-6-thiol, pale yellow, rhombic prisms, m. p. 180—181°.

4:6-Dimethylcoumarin-8-sulphonyl chloride crystallises in long, colourless needles, m. p. 179°, and is reduced with some difficulty to 4:6-dimethylcoumarin-8-thiol, colourless needles, incipient decomp. 246° (the *mercury* and *lead* derivatives are described). Ethyl 4:6-dimethylcoumarin-8-sulphonate forms lustrous needles, m. p. 182°.

3:4:7-Trimethylcoumarin is only slowly converted by sulphuric acid containing 50% of sulphur trioxide at 100° into 3:4:7-trimethylcoumarin-6-sulphonic acid, m. p. above 300°, the *sodium*, *lead*, and *potassium* salts of which are described. 3:4:7-Tri-

*methylcoumarin-6-sulphonyl chloride* crystallises in short, thick needles, m. p. 214°.

7-Methoxy-4-methylcoumarin is transformed into the corresponding *sulphonic acid*, a colourless, crystalline mass, under the same conditions as is 4:7-dimethylcoumarin. *Sodium 7-methoxy-4-methylcoumarin-6-sulphonate*, needles, and the corresponding *potassium* and *barium* salts are described. The sodium salt is converted by phosphorus pentachloride at 180° into *7-methoxy-4-methylcoumarin-6-sulphonyl chloride*, lustrous rhombs, m. p. 201°, which is further transformed into *ethyl 7-methoxy-4-methylcoumarinsulphonate*, needles or leaflets, m. p. 199°, and *7-methoxy-4-methylcoumarin-6-thiol*, small leaflets, m. p. 178° (the *mercury*, *lead*, and *sodium* compounds are described).

The coumarinthiols resemble the coumarins in their behaviour towards bromine; thus 4:7-dimethylcoumarin-6-thiol gives the corresponding *dibromide*,  $C_{11}H_{10}O_2SBr_2$ , long needles, m. p. 271°, which is readily decomposed by water into the thiol and bromide.

Chromone is not sulphonated at 70–80° by sulphuric acid containing 50% of sulphur trioxide. Under closely similar conditions, 2:3-dimethylchromone is transformed into 2:3-dimethylchromone-6-sulphonic acid,  $SO_3H \cdot C_6H_3$   $\begin{smallmatrix} \diagup CO \cdot CMe \\ | \\ O \cdot CMe \end{smallmatrix}$ , a colourless mass which

does not melt at a definite temperature. The corresponding *sodium salt* (+4H<sub>2</sub>O) and *lead salt* (+2H<sub>2</sub>O) are described. Attempts to convert the sodium salt into the sulphonyl chloride were unsuccessful.

H. W.

#### Syntheses of Arylsulphone Derivatives of Naphthapyrones, Hydroxynaphthapyrones, and Trihydroxybenzopyrones.

JULIUS TRÖGER and RICHARD DUNKEL (*J. pr. Chem.*, 1922, [ii], 104, 311–334).—By a method previously described (Tröger and Bolte, A., 1922, i, 267), arylsulphone derivatives of naphthapyrones, hydroxynaphthapyrones, and trihydroxybenzopyrones have been prepared, and their fission by alkaline hydrolysis has been studied.

The arylsulphonylnaphthapyrones resemble, in their behaviour towards alkali hydroxides, the arylsulphonylcoumarins (Tröger and Bolte, *loc. cit.*). The action of moderately strong aqueous potassium hydroxide leads first, with disruption of the lactone ring, to the potassium salt of the coumarinic acid, from which, on acidification, the original pyrone is regenerated; if, however, the hydrolysis is continued, potassium carbonate and a styrene derivative are produced. Concentrated alkali hydroxide (30–40%) causes fission of the pyrone into the hydroxyaldehyde and the salt of the arylsulphonylacetic acid, the latter then passing into potassium carbonate and an arylmethylsulphone.

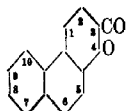

The hydroxyarylsulphonylcoumarins undergo fission more readily (*loc. cit.*) than the arylsulphonylcoumarins, but alkali carbonate and a styrene derivative are the sole products, the hydroxyaldehyde and the arylsulphonylacetic acid, or the arylmethylsulphone, not being formed. In contrast to this, the arylsulphonylhydroxynaphthapyrones are broken down by concentrated or

dilute alkali hydroxide into the relevant dihydroxynaphthaldehyde and an arylmethylsulphone.

Since trihydroxybenzaldehydes, which would be produced by the hydrolytic fission of arylsulphonyldihydroxycoumarins, are readily decomposed by alkali, the behaviour of the arylsulphonyldiethoxycoumarins has been studied, it being shown that whilst aqueous potassium hydroxide leads first to the salt of the coumarinic acid, acidification giving the original pyrone, by continued action neither an arylsulphone nor a styrol derivative is produced. The actual products have not yet been fully investigated.

It should be noted that the use of sodium ethoxide (Bilmmann, A., 1912, i, 461), for the fission of the pyrones described, is impracticable owing to their insolubility in alcohol. With the exception of the 3-arylsulphonyl-5:7-dihydroxycoumarins and the arylsulphonyldihydroxynaphthapyrones, all the compounds described show a pronounced fluorescence.

The reaction between  $\beta$ -naphthaldehyde, benzenesulphonyl-acetic acid (one-third of this as sodium salt), and acetic anhydride

commences in the cold, is completed on warming, and leads to 2-benzenesulphonyl-4:3- $\beta$ -naphthapyrone, pale yellow prisms, m. p. 253°. Similarly, acetic anhydride,  $\beta$ -naphthaldehyde, and *p*-toluenesulphonyl-acetic acid give 2-*p*-toluenesulphonyl- $\beta$ -naphthapyrone, pale yellow prisms, m. p. 275°, whilst the use of *p*-chlorobenzenesulphonyl-acetic acid leads to 2-*p*-chlorobenzenesulphonyl- $\beta$ -naphthapyrone, small, yellow prisms, m. p. 285°. The action of aqueous potassium hydroxide solution (10–30%) leads to known products (see above). 2:6-Dihydroxynaphthaldehyde condensed with benzenesulphonyl-acetic acid gives 8-acetoxy-2-benzenesulphonyl- $\beta$ -naphthapyrone, yellow leaflets, m. p. 246°, which on hydrolysis with 50% aqueous sulphuric acid gives 8-hydroxy-2-benzenesulphonyl- $\beta$ -naphthapyrone, flat, yellow prisms, m. p. above 270°. 8-Acetoxy-2-*p*-toluenesulphonyl- $\beta$ -naphthapyrone, flat, yellow prisms, m. p. above 265°, derived from *p*-toluenesulphonyl-acetic acid, gives 8-hydroxy-2-*p*-toluenesulphonyl- $\beta$ -naphthapyrone, m. p. above 270°, on hydrolysis; if *p*-chlorobenzenesulphonyl-acetic acid is used, 8-acetoxy-2-*p*-chlorobenzenesulphonyl- $\beta$ -naphthapyrone, a reddish-yellow, microcrystalline powder, m. p. about 274°, is produced, giving on hydrolysis 8-hydroxy-2-*p*-chlorobenzenesulphonyl- $\beta$ -naphthapyrone, thin needles of high m. p. 2:7-Dihydroxynaphthaldehyde, when condensed with the same three sulphonyl-acetic acids, gives 9-acetoxy-2-benzenesulphonyl- $\beta$ -naphthapyrone, yellow leaflets, m. p. 258°, 9-acetoxy-2-*p*-toluenesulphonyl- $\beta$ -naphthapyrone, yellow prisms, and 9-acetoxy-2-*p*-chlorobenzenesulphonyl- $\beta$ -naphthapyrone, yellowish-red prisms; hydrolysis gives, respectively, 9-hydroxy-2-benzenesulphonyl- $\beta$ -naphthapyrone, slender, yellow prisms, 9-hydroxy-2-*p*-toluenesulphonyl- $\beta$ -naphthapyrone, flat, yellow leaflets; and 9-hydroxy-2-*p*-chlorobenzenesulphonyl- $\beta$ -naphthapyrone, small, slender, yellowish-red prisms; all these compounds have high melting points. The action of aqueous alkali hydroxides on these hydroxy- or acetoxy-derivatives leads to known products (see above). The

condensation of pyrogallaldehyde with the same three acids gives 3-benzenesulphonyl-7:8-diacetoxycoumarin, small, white needles, m. p. 183°; 3-p-toluenesulphonyl-7:8-diacetoxycoumarin, white needles, m. p. 234°, and 3-p-chlorobenzenesulphonyl-7:8-diacetoxycoumarin, white needles, m. p. 223°, from which by hydrolysis 3-benzenesulphonyl-7:8-dihydroxycoumarin (+H<sub>2</sub>O), yellow prisms, m. p. 255°, 3-p-toluenesulphonyl-7:8-dihydroxycoumarin (+H<sub>2</sub>O), yellow needles, m. p. 258°, and 3-p-chlorobenzenesulphonyl-7:8-dihydroxycoumarin, yellow needles, m. p. 268° (decomp.), respectively, are obtained. From 2:4:5-trihydroxybenzaldehyde, 3-benzenesulphonyl-6:7-diacetoxycoumarin, white needles, m. p. 252°, 3-p-toluenesulphonyl-6:7-diacetoxycoumarin, white needles, m. p. 228°, and 3-p-chlorobenzenesulphonyl-6:7-diacetoxycoumarin, nodular aggregates of needles, m. p. 221°, are produced; hydrolysis gives, respectively, 3-benzenesulphonyl-6:7-dihydroxycoumarin, white needles of high m. p., 3-p-toluenesulphonyl-6:7-dihydroxycoumarin, yellow needles, m. p. 278° (decomp.), and 3-p-chlorobenzenesulphonyl-6:7-dihydroxycoumarin, small, yellowish-white needles of high melting point. From 2:3:5-trihydroxybenzaldehyde, 3-benzenesulphonyl-5:7-diacetoxycoumarin, white needles, m. p. 191°, 3-p-toluenesulphonyl-5:7-diacetoxycoumarin, white needles, m. p. 213°, and 3-p-chlorobenzenesulphonyl-5:7-diacetoxycoumarin, white needles, m. p. 211°, are obtained, giving on hydrolysis 3-benzenesulphonyl-5:7-dihydroxycoumarin, yellowish-brown, difficultly fusible needles, 3-p-toluenesulphonyl-5:7-dihydroxycoumarin, yellowish-white needles, m. p. 258—260° (decomp.), and 3-p-chlorobenzenesulphonyl-5:7-dihydroxycoumarin, very small, yellowish-white, difficultly fusible needles, respectively. The three last-mentioned dihydroxycoumarin derivatives, when alkylated by means of ethyl-alcoholic sodium ethoxide and ethyl iodide, give, respectively, 3-benzenesulphonyl-5:7-diethoxycoumarin, yellowish-white needles, m. p. 187°, 3-p-toluenesulphonyl-5:7-diethoxycoumarin, yellowish-white prisms, m. p. 227°, and 3-p-chlorobenzenesulphonyl-5:7-diethoxycoumarin, yellowish-white needles, m. p. 226°; the hydrolytic fission of these ethoxy-compounds requires the use of 20% aqueous alkali hydroxide, and has so far given, apart from recovered material, no recognisable product.

W. S. N.

**The Composition of "Chelalbines."** P. KARRER (*Helv. Chim. Acta*, 1923, 6, 232).—Fresh analyses of methylchelalbine (A., 1917, i, 349) give the empirical formula C<sub>21</sub>H<sub>17</sub>O<sub>4</sub>NMe, instead of C<sub>16</sub>H<sub>12</sub>O<sub>3</sub>NMe. The chelalbines are therefore to be regarded as alkyl dihydrochelerethrines, their formation corresponding with that of the alkyl dihydroberberines by the action of Grignard's reagent on berberine.

E. H. R.

**Gel Formation in Quinine and Eucupine Solutions.** PETER RONA and MAKI TAKATA (*Biochem. Z.*, 1922, 134, 97—107).—The conditions for gel formation in quinine and eucupine solutions have been rigidly defined. The range of variation of conditions for quinine is very small, 1.5 c.c. of a 1% quinine hydrochloride

solution with 3 c.c. of a  $M/3$  phosphate mixture of  $P_H$  6.85 giving a stiff gel which crystallised after five to ten minutes. In the case of eucupine, gels of considerable stability are obtainable. Gel formation depends on the  $P_H$  values above 4.5 being inimical, on the particular buffering solution used, and on the concentration of the eucupine solution. The process of gelation can be followed by viscosity measurements, change of surface tension, and conductivity measurements. The gelation is reversible and the gel is suitable for Liesegang ring formation.

### Indian Opium. III. The Meconic Acid Content of Indian Opium.

HAROLD E. ANNETT and MATHURA NATH BOSE (*Mem. Dept. Agric. India*, 1922, 6, 215—221).—The meconic acid was estimated in various samples of opium by the addition of calcium chloride solution to an aqueous extract of the opium and decomposition of the calcium salt by hydrochloric acid (A., 1922, ii, 791). The quantity of meconic acid is in all cases found to be roughly equivalent to that of the total alkaloids present, whereas the soluble sulphate content of the latex increases as the alkaloidal content diminishes, and it is concluded that the alkaloids are present as meconates only, the sulphate being present in a mineral form. The acid reaction of the latex is due to dissociation of the weakly basic alkaloids such as narcotine and papaverine. P. M.

### Preparation of Papaverine Nitrite.

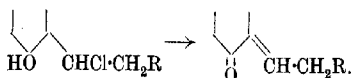

C. H. BOEHRINGER SOHN and HANS STENZL (Brit. Pat. 192298).—An aqueous solution of a papaverine salt is slowly treated with a 20% sodium nitrite solution either in the presence or absence of an organic solvent such as benzene. In the latter case, the oily reaction product consisting of a mixture of papaverine and papaverine nitrite is allowed to solidify, and after washing and drying is extracted with benzene until all the free alkaloid has been dissolved out. The residue consists of a 40% yield of the nitrite. When the reaction is carried out in presence of benzene the oil which separates quickly solidifies, and consists of almost pure papaverine nitrite. The substance forms an almost colourless, sandy powder which decomposes at about 140°, and, therapeutically, exhibits the tissue dilating properties of its components in an enhanced degree.

### Constitution of isoChondodendrine and Thebaine.

FRANZ FAITLS and THEODOR HECZKO (*Monatsh.*, 1923, 43, 377—385).—Ethyl chloroformate, in presence of potassium hydroxide, converts isoChondodendrine into a mixture of dicarbethoxyhydrochloroisochondodendrine, dicarbethoxyisochondodendrine, and N-carbethoxyhydrochloroisochondodendrine. Only a partial interaction occurs with respect to the phenolic group in the alkaloid, as in the case of bulbocapnine (A., 1921, i, 579). The product is optically active, giving  $[\alpha]_D -20^\circ$  in 96% alcohol. The chlorine atom present, from its reactivity, is apparently in the  $\alpha$ -position with respect to the benzene ring. On evaporating an alcoholic solution of the

above mixture, a carmine-red substance is formed, presumably as shown below :

By applying the Angeli-Rimini "nitroxyl reaction" to thebaizone, it is shown that the latter does not contain a free aldehyde-group, and therefore probably has the annexed formula (A), a certain amount of tautomeric change occurring, giving, also, (B). This result points to the correctness of the formula suggested by Faltis (A., 1917, i, 411) for thebaine.

**Strychnos Alkaloids. XXXVIII. Transformations of the Four Isomeric Brucinesulphonic Acids.** HERMANN LEUCHS and HEINZ ZANDER (*Ber.*, 1923, 56, [B], 502—509).—An extension of the work of Leuchs and Geiger (A., 1909, i, 828) and Leuchs and Fricker (A., 1922, i, 677).

Brucinesulphonic acid II is converted by hot 5*N*-nitric acid into the *nitroquinone hydrate* II,  $\text{C}_{21}\text{H}_{21}\text{O}_{10}\text{N}_3\text{S}$ , orange-red, hexagonal, domatic prisms or rectangular plates which gives a *monosemicarbazone*,  $\text{C}_{22}\text{H}_{24}\text{O}_{10}\text{N}_6\text{S}$ , thin, lemon-yellow needles or prisms. It is reduced by tin and concentrated hydrochloric acid to the *aminoquinol hydrochloride*,  $\text{C}_{21}\text{H}_{23}\text{O}_7\text{N}_3\text{S}\cdot\text{HCl}$ , colourless prisms, the water added previously to give the  $\cdot\text{CO}_2\text{H}/\text{HN}\cdot$  groups being again eliminated to  $\cdot\text{CO}\cdot\text{N}\cdot$ . It is converted by sulphurous acid into the *nitroquinol hydrate* II,  $\text{C}_{21}\text{H}_{23}\text{O}_{10}\text{N}_3\text{S}\cdot 3\text{H}_2\text{O}$ , aggregates of blackish-violet prisms or needles, which, like the corresponding compound from brucinesulphonic acid I, is converted by alcoholic hydrogen chloride into a violet *diethyl* derivative containing the carbethoxyl and the quinonoid,  $\cdot\text{NO}\cdot\text{OEt}$ , groups. It is transformed by acetic anhydride and sodium acetate into a *triacetyl* compound,  $\text{C}_{27}\text{H}_{23}\text{O}_{13}\text{N}_3\text{S}$ , short needles or five-sided plates.

Brucinesulphonic acid III is transformed by 5*N*-nitric acid into the *nitroquinone hydrate* III,  $\text{C}_{21}\text{H}_{21}\text{O}_{10}\text{N}_3\text{S}$ , orange-coloured, hexagonal platelets which is reduced by sulphurous acid to the *nitroquinol hydrate* III,  $\text{C}_{21}\text{H}_{23}\text{O}_{10}\text{N}_3\text{S}\cdot 3\text{H}_2\text{O}$ , lustrous, blackish-violet prisms or leaflets.

Brucinesulphonic acid, IV, and 5*N*-nitric acid at 0—10° yield the *quinone nitrite*,  $\text{C}_{21}\text{H}_{20}\text{O}_7\text{N}_2\text{S}\cdot\text{HNO}_2\cdot 5\text{H}_2\text{O}$ , red plates, whereas when the substances are heated together on the water-bath after

being diluted, the *nitroquinone hydrate*,  $C_{21}H_{21}O_{10}N_3S_2H_2O$ , orange, coloured, domatic prisms, separates. The latter substance is reduced by sulphurous acid to the *nitroquinol hydrate* IV,

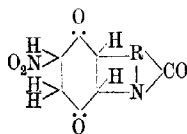

lustrous, pale reddish-violet needles or dark violet-red prisms.

The nitroquinone hydrate I is converted by saturated bromine water at  $15-20^\circ$  into the *product*,  $C_{21}H_{23}O_{11}N_3Br_2S_2 \cdot 2H_2O$ , pale yellow, oblique platelets or short prisms in which the water may be present as solvent of crystallisation; this cannot be regarded as definitely established, since the compound is so unstable that it can only be desiccated at  $20^\circ$ . A profound change appears, however, to have taken place, since sulphurous acid removes the bromine without regenerating the violet nitroquinol, in place of which a *product*,  $C_{21}H_{23}O_9N_3S$ , pale yellow, oblique, four-sided plates, is obtained in which the nitro-group is retained, since it is reduced by tin and hydrochloric acid to a colourless *amine* salt,

which evolves ammonia when boiled with potassium hydroxide solution. The absence of an oxygen atom in the new nitro-compound as compared with the nitroquinol hydrate is explained by the loss of water involved in the conversion of the groups  $-CO_2H:NH$  to  $:N-CO$ ; in this case, four atoms of hydrogen must have been added, which occurs probably as

indicated in the annexed formula, or a tautomeric form of it. One of the bromine atoms of the dibromide is certainly attached to the carbon atom united to the nitro-group, since it evolves bromonitromethane when boiled with water and gives a bromine-

free *acid*,  $C_{19}H_{22}O_9N_2S$ ; the latter contains the sulphonic acid group, thus indicating that this radicle cannot have been present in the aromatic nucleus of brucine, which suffers fission under these conditions.

The nitro-compound,  $C_{21}H_{23}O_9N_3S$ , gives with bromine a *product*,  $C_{21}H_{23}O_9N_3SBr_2$ , which differs completely from the previous bromo-derivative. It is not de-halogenated by sulphurous acid; it gives bromopicrin when boiled with water. H. W.

**Halogen Derivatives of Quinine.** SIGMUND FRÄNKEL, OTTO HERSCHMANN, and CHARLOTTE TRITT (*Ber.*, 1923, 56, [B], 433-438).—With the ultimate object of preparing derivatives of quinine in which the secondary alcoholic hydroxyl is replaced by an amino-group or the latter is present in the vinyl residue, the preparation of halogenated quinine compounds has been investigated. Quinine chloride is readily prepared by a modified method, but does not react in the desired sense with ammonia. On the other hand, quinine does not react simply with the bromides of phosphorus. Quinine chloride does not yield the bromide when heated above its melting point with potassium bromide, whereas with potassium iodide it gives a brown, amorphous substance.

Quinine is converted by phosphorus pentabromide (molecular

ratio, 3 : 7) in the presence of boiling chloroform into a resin which is partly dissolved when subsequently treated with ice-water. Addition of ammonia to the aqueous solution causes the precipitation of a colourless base, which rapidly becomes red. The precipitate does not appear to be uniform; after repeated purification, it gives analytical results approximating to those required by a dibromide. The portion which is undissolved by water contains two crystalline *tribromides*,  $C_{20}H_{22}ON_2Br_3$ , which have, respectively, m. p.  $109^\circ$  and  $[\alpha]_D^{19} + 198^\circ$  in methyl-alcoholic solution and  $235-245^\circ$  (corr. decomp.),  $[\alpha]_D^{19} + 119^\circ$  in chloroform. When quinine and phosphorus pentabromide in the molecular ratio 3 : 5 are allowed to react under similar conditions, the product is a *tribromide*, decomp.  $217^\circ$ , whereas when the substances are employed in molecular proportions a *dibromide*, m. p.  $130^\circ$ , is obtained. When quinine is treated with a molecular proportion of phosphorus tribromide, a monobromide appears to be produced, which, however, is mixed with a considerable proportion of unchanged quinine, from which it cannot be separated.

The preparation of quinine chloride,  $C_{20}H_{22}ON_2Cl$ , from quinine hydrochloride and phosphorus pentachloride is described in detail; the substance crystallises with half a molecular proportion of benzene. H. W.

**Japanese Yew Leaves. I. [Taxine].** HEISABURO KONDO and UMETARO AMANO (*J. Pharm. Soc. Japan*, 1922, 1074—1084; cf. Thorpe and Stubbs, T., 1902, 81, 874).—Taxine isolated from the leaves of yew (*Taxus baccata*) produced in the Province of Hida is a white, amorphous powder of bitter taste, m. p.  $105-111^\circ$  after sintering at  $82^\circ$ . Analysis confirmed the formula  $C_{37}H_{51}O_{10}N$  previously assigned to the alkaloid; in 5 and 10% alcoholic solutions it has  $[\alpha]_D^{18} + 32^\circ 20'$  and  $+35^\circ$ , respectively. Two chloroaurates were obtained (cf. *loc. cit.*), one, m. p.  $90-105^\circ$  (decomp.), soluble into hot dilute hydrochloric acid, and the other,  $C_{37}H_{51}O_{10}N \cdot HAuCl_4$ , m. p.  $110^\circ$  (decomp.), insoluble in hot dilute hydrochloric acid. When heated with 5% sulphuric acid, the alkaloid is partly decomposed, a compound reducing Fehling's solution being produced, which, however, has not the characteristics of sugar. Emulsin is without action on the alkaloid. When heated with alcoholic potash taxine is decomposed into formic and acetic acids, an amorphous acid, m. p.  $94-95^\circ$ , and molecular weight 215, a crystalline acid (perhaps cinnamic acid), m. p.  $133^\circ$ , and a compound,  $C_{23}H_{33}O_4N$ , m. p.  $105-110^\circ$ , insoluble in dilute sulphuric acid. By bromination in glacial acetic acid, the alkaloid gave a *tetrabromide*,  $C_{37}H_{51}O_{10}NBr_4$ , a yellow, amorphous powder, whilst in dilute sulphuric acid solution, a *tribromide*,  $C_{37}H_{51}O_{10}NBr_3$  or  $C_{37}H_{51}O_{10}NBr_2 \cdot HBr$ , a light yellow, amorphous powder, is formed. K. K.

**The Relationship between Constitution and Taste of Pepper.** I. H. STAUDINGER and HERMANN SCHNEIDER (*Ber.*, 1923, 56, [B], 699—711).—The investigation was undertaken with the object of finding a suitable substitute for pepper. The taste

of the latter is due to the presence of piperine, the physiological action of which is largely influenced by the dispersivity; the required taste is only developed when it is very finely divided.

Piperine has the constitution

For the development of the pepper taste, it is essential that the piperidine should be in amide-like union with an aliphatic-aromatic acid. It is most noticeable with derivatives of  $\delta$ -phenyl- $n$ -valeric acid. The possibilities of variation of the acidic component have been fully examined whilst those connected with the basic portion will be described in a subsequent communication. It is found that the presence of the methylenedioxy-group and of double bonds is not essential to the development of pepper taste, whilst also the stereochemical configuration of the chain does not appear to exert a marked influence. On the other hand, it is necessary that the phenyl group and the four carbon atoms in the side chain should be present. Piperine may be completely replaced by a mixture of the piperidides of  $\delta$ -phenyl- $\Delta^5$ - and - $\Delta^4$ -pentenoic acids dissolved in phellandrene.

Cinnamylidenemalonic acid is conveniently prepared in 88.6% yield by the action of glacial acetic acid on a mixture of calcium malonate and cinnamaldehyde at 60–70° and subsequent protracted heating of the product at 80°, and finally at 100°. It is converted by phosphorus pentachloride in the presence of benzene into *cinnamylidenemalonyl chloride*, golden-yellow crystals, m. p. 83°, which is stable towards water, and is transformed into a piperide which has not a pronounced taste of pepper.

Cinnamaldehyde reacts with malonic acid in the presence of pyridine to give cinnamenylacrylic acid, m. p. 165°, whereas in the presence of quinoline, *allocinnamenylacrylic acid*, m. p. 138°, is produced. (*Pyridine hydrogen cinnamylidenemalonate* crystallises in colourless needles, m. p. 114–115°, decomp., and gives when heated cinnamenylacrylic acid, m. p. 165°, in about 60% yield, and an acid of lower melting point which has not been investigated. *Quinoline hydrogen cinnamylidenemalonate* has m. p. 114–115° and decomposes at about 130° yielding mainly *allocinnamenylacrylic acid*, m. p. 138°, other non-crystalline acids and very little acid, m. p. 165°.) Cinnamenylacrylic acid, m. p. 165°, is converted into the corresponding *chloride*, m. p. 47°, by the action of a solution of thionyl chloride in boiling light petroleum and thence into the *piperidide*, m. p. 91–92°, which after being ground with flour during ten days has a very pronounced taste of pepper. *allo-Cinnamenylacrylic acid* is converted by similar methods into a non-crystalline *chloride* and *piperidide*; the taste of the latter appears to be indistinguishable from that of its isomeride.

Cinnamylidenemalonic acid is reduced by sodium amalgam in faintly alkaline solution to dihydrocinnamylidenemalonic acid, which is decomposed in boiling aqueous solution into  $\delta$ -phenyl- $\Delta^5$ -pentenoic acid; the corresponding *chloride*, a colourless liquid, b. p. 139–140°/12 mm., 98–100°/0.2 mm., prepared by the action of thionyl chloride in the presence of benzene or light petroleum;

the *anilide*, m. p. 80—82°; the *ethyl ester*, b. p. 154—156°/11 mm., and the *piperidide*, a viscous liquid, b. p. 163—165°/0.2 mm., are described. If, on the other hand, dihydrocinnamylidenemalonic acid is decomposed in the presence of boiling pyridine, it gives mainly  $\delta$ -phenyl- $\Delta^2$ -pentenoic acid; the corresponding *chloride*, a colourless liquid, b. p. 149—150°/15 mm., *anilide*, m. p. 115°; *ethyl ester*, a colourless liquid, b. p. 156—159°/13 mm., and *piperidide*, a viscous liquid, b. p. 164—169°/0.2 mm., are described.

[With E. PFISTER.]— $\delta$ -Phenyl- $\Delta^2$ -pentenoic acid is converted by thionyl chloride in the presence of boiling light petroleum into the corresponding *chloride*, b. p. 100—105°/0.15 mm., and thence into the *piperidide*, a pale yellow, viscous liquid, b. p. 165—167°/0.2 mm., which has a very marked taste of pepper.

[With H. BRÜTSCH.]— $\alpha$ -Phenylcinnamylacrylyl chloride, m. p. 87—89°, is prepared by the protracted action of a solution of thionyl chloride in boiling benzene on the corresponding acid and is converted into the *piperidide*, m. p. 135°, which has not a sharp taste.

[With A. GIUGLIEMETTI.]—Sorbyl chloride, b. p. 69—71°/12 mm., prepared from the acid and thionyl chloride in the presence of boiling benzene, gives the corresponding *piperidide*, m. p. 83—84°.

H. W.

**The Relationship between Constitution and Taste of Pepper. II. The Piperidides of Fatty-aromatic Acids.** H. STAUDINGER and FRITZ MÜLLER (*Ber.*, 1923, 56, [B], 711—715; cf. preceding abstract).—The taste of the piperidides of fatty-aromatic acids is influenced in an oscillating manner by the number of methylene groups in the chain, compounds with 2, 4, or 6 such groups having a sharper taste than those with 1, 3, or 5 groups. The taste of pepper is particularly pronounced in the case of the piperidide of  $\delta$ -phenyl-*n*-valeric acid. With unsaturated acids, the connexion between taste and constitution is not so marked, but the amount of material available scarcely permits exact conclusions to be drawn.

Phenylacetopiperidide, prepared from phenylacetyl chloride and piperidine, is an almost colourless liquid, b. p. 138—139°/0.4 mm.  $\beta$ -Phenylpropionylpiperidide, prepared similarly, has b. p. 147—150°/0.14 mm.  $\gamma$ -Phenylbutyric acid, m. p. 46—47°, is conveniently prepared in 94% yield of heating  $\beta$ -benzoylpropionic acid with hydrazine hydrate and sodium ethoxide at 180°; the corresponding *piperidide* has b. p. about 155°/0.25 mm.  $\delta$ -Phenylvaleric acid is readily prepared in large quantity by reducing cinnamylidenemalonic acid with sodium amalgam to dihydrocinnamylidenemalonic acid, and converting the latter by loss of carbon dioxide into  $\delta$ -phenyl- $\Delta^2$ -pentenoic acid, which is hydrogenated in alcoholic solution in the presence of platinum or in neutral aqueous solution in the presence of palladium; the acid has m. p. 57°. The corresponding *piperidide* is a liquid, b. p. about 164°/0.24 mm.  $\epsilon$ -Phenylhexoic acid is converted by thionyl chloride and benzene into the corresponding *chloride*, b. p. 151—

152°/11 mm., and thence into the *piperidide*, a pale yellow liquid, b. p. about 177°/0.05 mm.  $\zeta$ -Phenylheptioic acid, a colourless liquid which solidifies when strongly cooled, is conveniently prepared from  $\epsilon$ -phenylamyl bromide by the malonic ester synthesis; it yields successively the *chloride*, b. p. 166–168°/11 mm., and the *piperidide*, a pale yellow liquid, b. p. 184–188°/0.01 mm.

[With H. HALTEN.]—The *piperidide* of  $\gamma$ -phenyl- $\Delta^2$ -isocrotonic acid crystallises in colourless needles, m. p. 64–65°. H. W.

**The Formation of Quaternary Ammonium Salts.** I. EDWARD DE BARRY BARNETT, JAMES WILFRED COOK, and ERNEST PERCY DRISCOLL (T., 1923, 123, 503–518).

**The Dissociation of N-Pentamethylene-S-triarylmethylthiourethanes [Triarylmethyl Piperidine-1-carbodithionate] with the Formation of Triarylmethyls.** F. F. BLICKE (J. Amer. Chem. Soc., 1923, 45, 544–549).—Triphenylmethyl piperidine-1-carbodithionate and some of its homologues were prepared by the interaction of piperidine piperidine-1-carbodithionate and the corresponding triarylchloromethane. These esters in solution, at the ordinary temperature, dissociate with the formation of free triarylmethyl radicles, which on exposure to air are converted into their insoluble peroxides. Thus *triphenylmethyl piperidinocarbodithionate*,  $C_5H_{10}N-CS_2CPh_3$ , m. p. 155–160° (decomp.), gives triphenylmethyl peroxide; the *diphenyl- $\alpha$ -naphthylmethyl* ester gives diphenyl- $\alpha$ -naphthylmethyl peroxide, and the *diphenyldiphenylmethyl* ester gives diphenyldiphenylmethyl peroxide. W. G.

**Pyrroles. IV. Pyrrolealdehydes (II) and Pyrrolenitriles.** HANS FISCHER and WERNER ZERWECK (Ber., 1923, 56, [B],

519–527).—2:3:5-Trimethylpyrrole-4-aldehyde,  $NH < \begin{matrix} CMe:CMe \\ CMe:C:CHO \end{matrix}$  colourless crystals, m. p. 143.5°, is prepared in 66.6% yield by the action of hydrogen chloride on a solution of 2:3:5-trimethylpyrrole and anhydrous hydrogen cyanide in chloroform and decomposition of the product of the reaction with water; it is remarkable that the chloroform cannot be replaced by ether as solvent. The following derivatives are described: *phenylhydrazone*, coarse, brown crystals, m. p. 138°; *oxime*, colourless needles, m. p. 164°; *semicarbazone*, m. p. 198°; *aldazine*, m. p. 273° after previous darkening. Attempts to convert the aldehyde into 2:3:5-trimethylpyrrole-4-propionic acid were unsuccessful. The aldehyde is converted by hippuric acid and sodium acetate into the *azlactone*,  $C_{17}H_{18}O_2N_2$ , orange or reddish-brown needles, m. p. 198°, which is transformed by sodium hydroxide into 2:3:5-trimethylpyrrole-4-benzoylaminoacrylic acid,  $C_{17}H_{18}O_3N_2$ , m. p. 178° (decomp.), which could not, however, be reduced. Similarly, the propionic acid derivative could not be obtained through the product (m. p. 286°) of the condensation of the aldehyde with rhodamine.

2:4-Dimethylpyrrole-5-aldehyde is prepared in 92% yield by

the action of hydrogen chloride and hydrogen cyanide on 2:4-dimethylpyrrole in the presence of chloroform, whereas the yield is only moderate if ether is used as solvent (cf. Fischer and Zerweck, A., 1922, i, 758).

4-Cyanoacetyl-2:3:5-trimethylpyrrole is converted by alcoholic sodium hydroxide solution at 160° into 4-acetyl-2:3:5-trimethylpyrrole, m. p. 207°.

A series of pyrrolenitriles, in which the cyano-group is attached to a ring carbon atom, has been prepared from the aldehydes through the oximes; reaction proceeds so smoothly that the method is of preparative value. Thus, ethyl 4-aldehyde-2:5-dimethylpyrrole-3-carboxylate is converted into the *oxime*, colourless crystals, m. p. 223° (decomp.), which is transformed by acetic anhydride and anhydrous sodium acetate into ethyl 4-cyano-2:5-

dimethylpyrrole-3-carboxylate,  $\text{NH} < \begin{matrix} \text{CMe}=\text{C}\cdot\text{CN} \\ \text{CMe}=\text{C}\cdot\text{CO}_2\text{Et}' \end{matrix}$  colourless, lustrous needles, m. p. 152°. Ethyl 5-cyano-2:4-dimethylpyrrole-3-carboxylate forms colourless crystals, m. p. 159°; 4-cyano-2:3:5-trimethylpyrrole has m. p. 140°.

Attempts to prepare 2:3:4:5-tetramethylpyrrole by the action of hydrogen iodide and glacial acetic acid on 2:3:5-trimethylpyrrole-4-aldehyde were unsuccessful, owing to loss of the formyl groups. (Ethyl 5-aldehyde-2:4-dimethylpyrrole-3-carboxylate is converted under similar conditions into 2:4-dimethylpyrrole.) The tetramethyl compound is, however, obtained by the action of alcoholic sodium ethoxide solution at 150–160° on the semicarbazone of 2:3:5-trimethylpyrrole-4-aldehyde; it is isolated as the *picrate*, coarse, yellow crystals, m. p. 130°. Similarly, ethyl 4-aldehyde-2:5-dimethylpyrrole-3-carboxylate semicarbazone, colourless crystals, decomp. 257° after softening at about 244°, yields 2:3:5-trimethylpyrrole.

The stability of the formyl group in substituted pyrroles towards alkali hydroxide is remarkable. Thus, 2:3:5-trimethylpyrrole-4-aldehyde is unchanged by boiling, aqueous sodium hydroxide solution (20%); ethyl 5-aldehyde-2:4-dimethylpyrrole-3-carboxylate is converted into 5-aldehyde-2:4-dimethylpyrrole-3-carboxylic acid, m. p. 283–284° (decomp.), and ethyl 4-aldehyde-2:5-dimethylpyrrole-3-carboxylate gives 4-aldehyde-2:5-dimethylpyrrole-3-carboxylic acid, m. p. 248° (decomp.).

2:4-Dimethylpyrrole-5-aldehyde is transformed by concentrated hydrochloric acid into *di*-2:4-dimethylpyrrolmethene, m. p. 18°. *Di*-3-carbethoxy-2:4-dimethylpyrrolmethene hydrochloride is most conveniently prepared by heating ethyl 2:4-dimethylpyrrole-3-carboxylate dissolved in concentrated hydrochloric acid with an excess of formic acid; the corresponding base crystallises in long, dark red needles, m. p. 190°.

4-Chloroacetyl-2:3:5-trimethylpyrrole is converted by an alcoholic solution of dimethylamine into 4-dimethylaminoacetyl-2:3:5-trimethylpyrrole hydrochloride, colourless crystals, m. p. 48°; the corresponding base has m. p. 130°. 4-Phthalimidoacetyl-2:3:5-trimethylpyrrole has m. p. 227°.

H. W.

**Hydroxypyrrole Derivatives. III.** ERICH BENARY and WILHELM LAU (*Ber.*, 1923, 56, [B], 591—597; cf. Benary and Silbermann, A., 1913, i, 651).—An account of partly completed work induced by the recent publications of Küster (A., 1922, i, 857), Küster and Maag (this vol., i, 242), and Fischer and Hermann (A., 1922, i, 1054).

*C-Chloroacetyldiacetonitrile*,  $\text{NH}_2\cdot\text{CMe}\cdot\text{C}(\text{CN})\cdot\text{CO}\cdot\text{CH}_2\text{Cl}$ , colourless needles, m. p.  $155^\circ$ , is prepared by the action of chloroacetyl chloride on diacetonitrile in the presence of pyridine. The constitution of the compound follows from the observation that it is converted by potassium hydrogen sulphide into the corresponding *sulphide*,  $[\text{NH}_2\cdot\text{CMe}\cdot\text{C}(\text{CN})\cdot\text{CO}\cdot\text{CH}_2]_2\text{S}$ , colourless, matted needles, m. p.  $178\text{--}179^\circ$ , in which the amino-group is readily replaced by hydroxyl by means of *N*-sodium hydroxide solution with production of the *dienol*,  $[\text{OH}\cdot\text{CMe}\cdot\text{C}(\text{CN})\cdot\text{CO}\cdot\text{CH}_2]_2\text{S}$ , colourless needles, m. p.  $130^\circ$ . The conversion of the chloroacetyl compound into the corresponding hydroxypyrrole has not yet been accomplished definitely. In general, the preparation of the latter compounds can frequently be satisfactorily effected only under very definite experimental conditions, which must be established for each particular case.

*C-Chloroacetyl-N-phenyldiacetonitrile*,

colourless leaflets, m. p.  $103\text{--}104^\circ$ , is prepared from *N*-phenyldiacetonitrile and chloroacetyl chloride in the presence of pyridine and ether, and is transformed by potassium hydrogen sulphide into the *sulphide*,  $\text{C}_{24}\text{H}_{22}\text{O}_2\text{N}_4\text{S}$ , colourless needles, m. p.  $170\text{--}172^\circ$ . It is transformed by potassium hydroxide in the presence of methyl alcohol into 4-hydroxy-1-phenyl-2-methylpyrrole-3-nitrile,

colourless needles, m. p.  $167^\circ$ , which is converted by nitrous acid into 5-oximino-4-keto-1-phenyl-2-methylpyrroline-3-nitrile, orange-yellow needles, decomp.  $178^\circ$  after darkening at about  $160^\circ$ , and by sodium nitrite and glacial acetic acid into 5-nitroimino-4-keto-

1-phenyl-2-methylpyrroline-3-nitrile,  $\text{PhN} \begin{array}{c} \text{CMe} \\ \diagdown \quad \diagup \\ \text{C}(\text{N}\cdot\text{NO}_2)\cdot\text{CO} \end{array}$ , an

orange-coloured precipitate, decomp.  $225^\circ$ . The latter substance is transformed by sodium hydroxide solution (5%) into the substance,  $\text{NPh}\cdot\text{CMe}\cdot\text{C}(\text{CO}\cdot\text{NH}_2)\cdot\text{C}(\text{OH})\cdot\text{CO}\cdot\text{NH}\cdot\text{NO}_2$ , pale-yellow, four-sided plates, decomp.  $240\text{--}241^\circ$  after becoming altered at  $237^\circ$ , which, with phenylhydrazine in the presence of acetic acid (50%), yields the compound,

$\text{C}_6\text{H}_4\cdot\text{C}(\text{CO}\cdot\text{NH}_2)\cdot\text{CMe}\cdot\text{NPh}$ , brownish-yellow needles or four-sided prisms, decomp.  $225^\circ$  after gradual darkening and softening above  $205^\circ$ .

*C-Chloroacetylbenzoacetodinitrile*,  $\text{NH}_2\cdot\text{CPh}\cdot\text{C}(\text{CN})\cdot\text{CO}\cdot\text{CH}_2\text{Cl}$ , long, colourless needles, m. p.  $116^\circ$ , is converted in the usual manner into the corresponding *sulphide*,  $\text{C}_{22}\text{H}_{18}\text{O}_2\text{N}_4\text{S}$ , colourless needles, m. p.  $195\text{--}198^\circ$ . Attempts to transform it into the corresponding

pyrrole resulted in the production of a reddish-violet dye, decomp. about 250°, for which the constitution

is suggested.

H. W.

**Potassium Iridodipyridinodioxalates.** MARCEL DELÉPINE (*Compt. rend.*, 1923, 176, 445—447).—When *r-cis*-potassium iridodichlorodioxalate is heated with pyridine at 130° for four hours, a crystalline potassium iridodipyridinodioxalate,

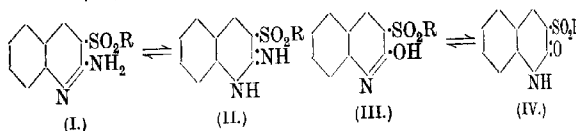

is obtained together with an amorphous product, which has the same composition as the crystalline product. The crystalline salt when treated with aqua regia is converted into a dipyridino-iridium tetrachloride, which with ammonia gives the same special complexes as the chloride from the red salts. Similarly, if the dioxalate is treated with hydrochloric acid, it gives a series of compounds among which is an iridodipyridino-tetrachloride of iridodichlorodiaquodipyridine. This salt reacts with alkalis to give a red iridodipyridino-tetrachloride, and a hydroxy-compound which is an anhydride of the theoretical hydroxide of the salt,  $\text{Ir}(\text{C}_5\text{H}_5\text{N})_2(\text{H}_2\text{O})(\text{OH})\text{Cl}_2$ . The other products formed in the decomposition by hydrochloric acid are the aquodipyridinoiridium chloro-oxalate,  $\text{Ir}(\text{C}_5\text{H}_5\text{N})_2(\text{H}_2\text{O})\text{Cl}(\text{C}_2\text{O}_4)$ , a neutral substance insoluble in water but soluble in alkalis, and iridodichlorodiaquodipyridine chloride,  $\text{Cl}[\text{Ir}(\text{C}_5\text{H}_5\text{N})_2(\text{H}_2\text{O})_2\text{Cl}_2]$ , and traces of potassium pyridinoiridium pentachloride. The iridodipyridinodioxalate is therefore, apparently a *trans*-dipyridino-compound formed by intramolecular transpositions. The amorphous compounds obtained along with it are the *cis*-compounds and give orange-coloured salts under the influence of hydrochloric acid. W. G.

**Amino-alcohols, Ketones, and other Derivatives of the Quinoline Series.** K. MIESCHER (U.S. Pat. 1434306).—*Ethyl 2-phenylquinoline-4-acetate*, yellow prisms, m. p. 52—54°, is obtained from the reaction products of ethyl 2-phenylquinoline-4-carboxylate, sodium ethoxide, and ethyl acetate heated in toluene for twenty-four hours. It forms a sparingly soluble, bright green copper salt, and intensely yellow salts with hydrochloric and sulphuric acids. *2-Phenyl-4-quinolyl methyl ketone*, yellow crystals, m. p. 73°, is formed by heating ethyl 2-phenylquinoline-4-acetate with eight times its weight of 25% sulphuric acid and treating the reaction mass with sodium carbonate and ether, or from a solution of 4-cyano-2-phenylquinoline in benzene treated drop by drop, with cooling, with a solution of magnesium methyl iodide in ethyl ether (*hydrobromide*, yellow, m. p. 240°). Bromination of the ketone in concentrated hydrobromic acid or an organic solvent yields the *hydrobromide*, m. p. about 225° (decomp.), of *2-phenyl-4-quinolyl bromomethyl ketone*, bright yellow crystals, m. p. 91°. The latter hydrobromide reacts in benzene cooled with ice with dimethylamine, subsequent treatment with alcoholic hydrogen

chloride giving 2-phenyl-4-quinolyl dimethylaminoethyl ketone mono-hydrochloride, yellow crystals, m. p. 208° (decomp.) (hydrobromide, m. p. about 206°). 2-Phenyl-4-quinolyl diethylaminoethyl ketone monohydrochloride forms bright yellow needles, m. p. about 164° (decomp.); 2-phenylquinolyl 4-piperidylethyl ketone monohydrochloride has m. p. 235° [monohydrobromide, m. p. about 241° (decomp.)]. Amino-alcohols containing a primary amino-group can be prepared by reducing the corresponding oximinoketones, *N*-substituted amino-alcohols being similarly obtained from amino-ketones. 2-Phenyl-4-quinolylaminoethanol dihydrochloride forms yellow crystals, m. p. 145°. 2-Phenyl-4-quinolyl dimethylaminoethanol dihydrochloride has m. p. about 175° (decomp.), and the corresponding diethylamino compound, m. p. about 185°. 2-Phenyl-4-quinolylpiperidylethanol has m. p. about 54° (monohydrochloride, m. p. about 162°; dihydrochloride, m. p. about 199°).

CHEMICAL ABSTRACTS.

**Syntheses of 2- and 3-Substituted Quinolines.** JULIUS TRÖGER and PAUL KÖPPEN-KASTROP (*J. pr. Chem.*, 1922, [ii], 104, 335—367).—The condensation of *o*-aminobenzaldehyde with an arylsulphonylacetonitrile, using pyridine as catalyst, gives, instead of the expected product  $\text{RSO}_2\text{C}(\text{CN})\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{NH}_2$ , a quinoline derivative (I), in the formation of which both hydrogen atoms of the amino-group must have migrated to the nitrogen of the cyano-group (cf. Pshorr, A., 1898, i, 491); the same compound is produced by the re-

duction in alcoholic hydrogen chloride solution with stannous chloride of the condensation product,  $\text{RSO}_2\text{C}(\text{CN})\text{CH}\cdot\text{C}_6\text{H}_4\cdot\text{NO}_2$ , of *o*-nitrobenzaldehyde and an arylsulphonylacetonitrile. Nitrous acid converts these aminoquinolines into carbostyryl derivatives (III), the structure of which is firmly established by their synthesis from *o*-aminobenzaldehyde and (a) the arylsulphonylacetic acid, (b) its ester, or (c) its amide, with elimination of (a) water, (b) alcohol, or (c) ammonia, respectively. Although these carbostyryl derivatives are insoluble in aqueous alkali, they form sodio-derivatives in the absence of water, which lead to 3-arylsulphonyl-2-alkoxyquinolines when treated with alkyl halides under pressure; moreover, the hydroxyl may be replaced by chlorine by means of phosphorus pentachloride. Hence these carbostyryls are best represented as tautomeric in the sense  $\text{(III)} \rightleftharpoons \text{(IV)}$ . The properties of the amino-compounds are less easy to explain. They are insoluble in concentrated hydrochloric acid, and cannot be diazotised even at a high temperature and pressure, neither do they react with methyl iodide, although with this reagent the  $\beta$ -arylsulphonylmethylquinolines (Tröger and Menzel, A., 1922, i, 269) form crystalline derivatives. It is equally surprising that the salts and double

salts are much more readily dissociated than those of the corresponding 2-methyl derivatives. This is even difficult to understand if a tautomeric form (II) is assumed, since this should give at least a mono-alkyl derivative. Nitrous acid would then convert (II) into (IV). The formation of the  $\alpha$ -chloro-compound is certainly more easily explained on formula (III); nevertheless, the action of a large excess of phosphorus halide leads to a dichloro-derivative, possibly derived from the keto-form (IV).

The 2-chlorine atom is readily replaceable by ethoxyl (using sodium ethoxide); also by the  $\cdot\text{SH}$  group (by means of alcoholic potassium hydrosulphide) giving a thiocarbostyryl, which is soluble in aqueous alkali and more readily alkylated than the carbostyryl itself. Replacement by the group  $\text{R}\cdot\text{SO}_2\cdot$ , by the action of a salt of an arylsulphinic acid, proceeds only slowly, whilst the replacement by the group  $\text{Na}\cdot\text{SO}_3\cdot$  (by means of sodium sulphite, cf. Besthorn and Geisselbrecht, A., 1920, i, 563) has not been accomplished.

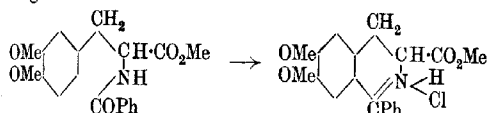

The above reactions have been investigated when R is  $\text{C}_6\text{H}_5\cdot$ ,  $\text{H}_3\cdot\text{C}_6\text{H}_4\cdot(p)$ , and  $\text{Cl}\cdot\text{C}_6\text{H}_4\cdot(p)$ .

Equimolecular quantities of *o*-nitrobenzaldehyde and benzenesulphonylacetonitrile give, when treated in concentrated alcoholic solution with a little pyridine,  $\beta$ -*o*-nitro- $\alpha$ -benzenesulphonylcinnamionitrile, long, slender, white needles, m. p.  $149^\circ$ , which on reduction by means of stannous chloride and hydrochloric acid in alcoholic solution is converted into 2-amino-3-benzenesulphonylquinoline, long, white needles, m. p.  $206^\circ$ , which is also produced by heating *o*-aminobenzaldehyde and benzenesulphonylacetonitrile in alcoholic solution with a little aqueous sodium hydroxide. The hydrochloride, needles, decomp.  $100^\circ$ , the nitrate, needles, decomp.  $70^\circ$ , the hydrogen sulphate, yellow needles, decomp.  $105^\circ$ , the hydrogen oxalate, the perchlorate, the chloroplatinate,  $(\text{C}_{15}\text{H}_{12}\text{O}_2\text{N}_2\text{S})_2\cdot\text{H}_2\text{PtCl}_6\cdot\text{H}_2\text{O}$ , reddish-yellow needles, and the chloroaurate,  $\text{C}_{15}\text{H}_{12}\text{O}_2\text{N}_2\text{S}\cdot\text{HAuCl}_4$ , golden needles, m. p.  $200^\circ$ , are described. The amino-compound, which cannot be alkylated, reacts in somewhat dilute acetic acid solution with sodium nitrite to give 3-benzenesulphonylcarbostyryl, long, rod-like prisms, m. p.  $312^\circ$ , which is also produced when *o*-aminobenzaldehyde is heated under pressure with either ethyl benzenesulphonylacetate or benzenesulphonylacetonitrile. 3-Benzenesulphonyl-2-thoxyquinoline, small, pale yellow prisms, m. p.  $190^\circ$ , is produced by heating the sodium salt of the carbostyryl in alcoholic suspension with methyl iodide under pressure, more readily by the action of sodium ethoxide at  $100^\circ$  on 2-chloro-3-benzenesulphonylquinoline, broad, rod-like crystals, m. p.  $150^\circ$ , which is produced by heating the  $\alpha$ -hydroxy-compound at  $160^\circ$  with phosphorus pentachloride and a few drops of phosphoryl chloride. When this chloro-derivative is heated at  $100^\circ$  with sodium benzenesulphinate, 2 : 3-dibenzesulphonylquinoline, small, yellowish-white needles, m. p.  $204^\circ$ , is formed, the 2-substituent of which is replaced by hydroxyl by fusion with alkali hydroxide; with alcoholic potassium hydrosulphide at  $100^\circ$ , the product is 3-benzenesulphonylthiocarbostyryl, long slender, yellow needles, m. p.  $241^\circ$ , which, when shaken with

methyl sulphate and dilute aqueous sodium hydroxide, gives a *s*-methyl derivative, long, yellow needles, m. p. 175°. The condensation of *o*-nitrobenzaldehyde with *p*-toluenesulphonylacetonitrile by means of pyridine in alcoholic solution leads to *o*-nitro- $\alpha$ -*p*-toluenesulphonylcinnamonnitrile, long, yellowish-white needles, m. p. 152°, which on reduction gives 2-amino-3-*p*-toluenesulphonylquinoline, sulphur-yellow, rod-like crystals, m. p. 214°, which is also produced by the condensation of *o*-aminobenzaldehyde with *p*-toluenesulphonylacetonitrile; the hydrochloride, slender needles, decomp. 100°, the nitrate, slender needles, decomp. 70°, the hydrogen sulphate, decomp. 100°, the hydrogen oxalate, the chloroplatinate (+H<sub>2</sub>O), reddish-yellow prisms, and the chloroaurate, slender, golden-yellow needles, m. p. 207°, are described. 3-*p*-Toluenesulphonylcarbostyryl, small, yellow prisms, m. p. 300°, is formed from the amino-compound by the action of nitrous acid, and also by heating *o*-aminobenzaldehyde at 160–170° with ethyl *p*-toluenesulphonylacetate, *p*-toluenesulphonylacetic acid, or *p*-toluenesulphonylacetamide; it forms a yellowish-white sodium salt when treated with alcoholic sodium ethoxide. The *O*-ethyl ether, m. p. 207–207.5°, can only be prepared by the action of alcoholic sodium ethoxide at 100° on 2-chloro-3-*p*-toluenesulphonylquinoline, m. p. 178–179°, which is best prepared by the action of a slight excess of phosphorus pentachloride and a little phosphoryl chloride on the carbostyryl. By the use of a large excess of these reagents, a material, m. p. 132°, probably 2:2-dichloro-3-*p*-toluenesulphonylquinoline, has been isolated (see above), and also a product, m. p. 122–124°, containing 2% more chlorine than the dichloro-compound.  $\alpha$ -*p*-Chlorobenzenesulphonyl-*o*-nitrocinnamonnitrile, long, white needles, m. p. 156°, is formed from *o*-nitrobenzaldehyde and *p*-chlorobenzenesulphonylacetonitrile, and gives on reduction 2-amino-3-*p*-chlorobenzenesulphonylquinoline, yellow prisms, m. p. 205°, which is also produced by the condensation of *o*-aminobenzaldehyde with *p*-chlorobenzenesulphonylacetonitrile; the hydrochloride, fine needles, the nitrate, slender, white needles, the hydrogen sulphate, fine, white needles, and the hydrogen oxalate, white needles, have been prepared. This amino-compound gives, with nitrous acid, 3-*p*-chlorobenzenesulphonylcarbostyryl, yellow prisms (+16% water or acetic acid), m. p. 287°, which is also formed by the condensation at 170° of *o*-aminobenzaldehyde with ethyl *p*-chlorobenzenesulphonylacetate, and gives with sodium ethoxide a yellow, amorphous sodium salt. The *O*-ethyl ether, slender, white needles, m. p. 173°, is formed by the action of alcoholic sodium ethoxide under pressure on 2-chloro-3-*p*-chlorobenzenesulphonylquinoline, slender, ivory-coloured needles, m. p. 170°, which is produced by the action of phosphorus pentachloride and a little phosphoryl chloride on the carbostyryl. This 2-chloro-derivative, when heated at 100° in alcoholic solution with potassium hydrogen sulphide, gives impure 3-*p*-chlorobenzenesulphonylthiocarbostyryl, a yellow, amorphous substance, which with dilute aqueous sodium hydroxide and methyl sulphate gives the *S*-methyl ether, long, slender, yellow needles, m. p. 194°.

W. S. N.

**Preparation of Derivatives of Dihydroisoquinoline.** SOCIETY OF CHEMICAL INDUSTRY IN BASLE (Brit. Pat. 191233).—Therapeutically active derivatives of dihydroisoquinoline are obtained by hydrogenising  $\alpha$ -acylaminocinnamic esters or their nuclear substitution derivatives, and converting the dihydrocinnamic acid derivatives thus produced into derivatives of dihydroisoquinoline-3-carboxylic acid by suitable condensing agents such as phosphoryl chloride. The parent materials are obtained by heating equimolecular proportions of an aromatic aldehyde, an acylated glycine, and sodium acetate with 3 mols. of acetic anhydride, and esterifying the product, and details are given of the conversion of the following substances into isoquinoline derivatives. Methyl veratralhippurate (methyl  $\alpha$ -benzamido-3:4-dimethoxycinnamate) is hydrogenised by means of a nickel catalyst at 55° to methyl  $\alpha$ -benzamido- $\beta$ -3:4-dimethoxyphenylpropionate, fleecy needles, m. p. 104–105°, which when heated with an equal weight of phosphoryl chloride is converted into methyl 6:7-dimethoxy-1-phenyl-3:4-dihydroisoquinoline-3-carboxylate, m. p. 122·5°, according to the following scheme :

The hydrochloride and hydrobromide form yellow crystals easily soluble in water, and in common with other 6:7-dihydroxy-derivatives they have the same therapeutic action as hydrastinine, but are less poisonous. With the free ester methyl iodide gives a *N*-methiodide which is sparingly soluble in water. Piperonylidenehippuric acid is in a similar way converted through  $\alpha$ -benzamido- $\beta$ -piperonylpropionic acid into methyl 6:7-methylenedioxy-1-phenyl-3:4-dihydroisoquinoline-3-carboxylate, small, colourless needles, m. p. 140·5°, which gives a hydrochloride, and a methiodide similar to those above described. Methyl  $\alpha$ -piperonylamino-3:4-methylenedioxy-cinnamate, m. p. 156–157°, yields on hydrogenation methyl  $\alpha$ -piperonylamino-3:4-methylenedioxyphenylpropionate, lustrous needles, m. p. 139–140°, which on condensation with phosphoryl chloride gives methyl 1-piperonyl-6:7-methylenedioxy-3:4-dihydroisoquinoline-3-carboxylate, m. p. 140–141°. The hydrochloride dissociates partly when dissolved in water. Methyl  $\alpha$ -cinnamoylamido-3:4-methylenedioxy-cinnamate, m. p. 192°, is in like manner converted into methyl  $\alpha$ -[ $\beta$ -phenylpropionylamido]-3:4-methylenedioxy-phenylpropionate, m. p. 127°, and then into methyl 6:7-methylenedioxy-1-phenylethyl-3:4-dihydroisoquinoline-3-carboxylate, thick prisms, m. p. 111°. The hydrochloride gives a bluish-green fluorescence in aqueous solution, and the methochloride is readily soluble in water, but less strongly fluorescent.

G. F. M.

**Synthesis of Asymmetric Homotetrahydroisoquinoline.** JULIUS VON BRAUN and FRIEDRICH ZOBEL (Ber., 1923, 56, [B], 690–696).—Previous attempts to synthesise homotetrahydroiso-

quinoline,  $C_6H_4 \begin{smallmatrix} \text{[CH}_2\text{]}_3 \\ \text{CH}_2 \end{smallmatrix} > NH$ , starting from *o*- $\gamma$ -phenoxypropylbenzonitrile, have been unsuccessful, since the initial step, namely the reduction of the cyano- to the amino-methylene group could not be effected by nascent hydrogen. Since, however, the author's experience has shown that catalytic hydrogenation is frequently more effective than treatment with nascent hydrogen, the study has been resumed. A preliminary series of experiments shows that the change can be effected under sufficiently great pressure in the presence of nickel compounds in the cases of simpler and less costly compounds. The desired synthesis is finally affected on the lines of the scheme:  $CN \cdot C_6H_4 \cdot [CH_2]_3 \cdot OPh \rightarrow NH_2 \cdot CH_2 \cdot C_6H_4 \cdot [CH_2]_3 \cdot OPh \rightarrow NH_2 \cdot CH_2 \cdot C_6H_4 \cdot [CH_2]_3 \cdot Cl \rightarrow C_6H_4 \begin{smallmatrix} \text{[CH}_2\text{]}_3 \\ \text{CH}_2 \end{smallmatrix} > NH$ . The product

appears to contain a seven-membered ring, but the authors promise an exact proof of its constitution later.

[With (Frl.) A. NELKEN.]—*o*-Methoxy-*o*-toluonitrile, a colourless liquid, b. p.  $114^\circ/14$  mm., is converted by hydrogenation at  $100^\circ$  in the presence of tetra- or deca-hydronaphthalene into a mixture of *o*-methoxymethylbenzylamine,  $OMe \cdot CH_2 \cdot C_6H_4 \cdot CH_2 \cdot NH_2$ , a mobile liquid, b. p.  $127-128^\circ/13$  mm. (hydrochloride, m. p.  $113^\circ$ ; picrate, m. p.  $164^\circ$ ; benzoyl derivative, m. p.  $71^\circ$ ), and *di*-*o*-methoxymethylbenzylamine,  $[OMe \cdot CH_2 \cdot C_6H_4 \cdot CH_2]_2 \cdot NH$ , an almost colourless, viscous liquid, b. p.  $200-205^\circ/13$  mm. (the hydrochloride and nitroso-derivative are non-crystalline; the picrate has m. p.  $156^\circ$ ).

[With G. BLESSING.]—*o*-Phenoxy-*o*-toluonitrile, m. p.  $65^\circ$ , is transformed into a mixture of *di*-*o*-phoxymethylbenzylamine, m. p.  $53^\circ$ , which yields a very sparingly soluble hydrochloride, m. p.  $158^\circ$ , and *o*-phoxymethylbenzylamine b. p.  $195-200^\circ/13$  mm., m. p.  $26-27^\circ$  (hydrochloride, m. p.  $200^\circ$ ; picrate, m. p.  $190^\circ$ ).

*o*-Methoxy-*o*-toluonitrile, b. p.  $125-127^\circ/12$  mm., yields *p*-methoxymethylbenzylamine, a colourless, mobile liquid, b. p.  $125-130^\circ/12$  mm. (hydrochloride, needles, m. p.  $205^\circ$ ; picrate, m. p.  $179^\circ$ ; acetyl derivative, colourless crystals, m. p.  $86-87^\circ$ ; phenylthiocarbamide compound, m. p.  $102-103^\circ$ ), *di*-*p*-methoxymethylbenzylamine, a colourless, rather viscous liquid, b. p.  $195-200^\circ/1$  mm. (hydrochloride, m. p.  $215^\circ$ ; a non-crystalline picrate; nitroso-derivative, m. p.  $120^\circ$ ), and apparently a small quantity of tri-*p*-methoxymethylbenzylamine.

*o*- $\gamma$ -Phenoxypropylbenzonitrile is readily hydrogenated in the presence of decahydronaphthalene at  $115^\circ$ , although the action does not proceed quite to completion. The products of the change are *o*- $\gamma$ -phenoxypropylbenzylamine (about 30%) and *di*-*o*- $\gamma$ -phenoxypropylbenzylamine, which could not be distilled without undergoing decomposition, and for the present has not been investigated further. The primary base crystallises in colourless needles, m. p.  $55^\circ$ , b. p.  $230^\circ/18$  mm.; it yields a hydrochloride, m. p.  $154^\circ$ , and a picrate, pale yellow, lustrous needles, m. p.  $171^\circ$ . It is converted by concentrated hydrochloric acid at  $130^\circ$  (the experimental conditions must be exactly observed) into *o*- $\gamma$ -chloropropylbenzylamine,

a colourless, somewhat unstable liquid, which is characterised as the *hydrochloride*, m. p.  $172^{\circ}$ , and the *picrate*, coarse needles, m. p.  $175^{\circ}$ , after slight previous softening. An aqueous solution of the hydrochloride is converted by an excess of warm dilute alkali hydroxide solution into *as.-homotetrahydroisoquinoline*, which is volatile with steam. It is a colourless liquid with an odour of tetrahydroisoquinoline, b. p.  $120^{\circ}/17$  mm. It could not be caused to solidify. On exposure to air it becomes transformed into the carbonate. It yields a solid, very hygroscopic *hydrochloride*, a *chloroplatinate*, a crystalline powder, m. p.  $192^{\circ}$ , and a *nitro-derivative*, m. p.  $73-74^{\circ}$ . When treated with methyl iodide and alkali hydroxide, it gives the quaternary *iodide*,  $C_{12}H_{18}NI$ , m. p.  $182^{\circ}$ .  
H. W.

**Derivatives of Tetrahydrocarbazole. II.** WILLIAM HENRY PERKIN, jun., and SYDNEY GLENN PRESTON PLANT (T., 1923, 123, 676-695).

**The Action of Nitrobenzene on the Sodium and Potassium Derivatives of Carbazole.** GUILLAUME DE MONTMOLLIN and MARCEL DE MONTMOLLIN (*Helv. Chim. Acta*, 1923, 6, 94-101).—The sodium and potassium derivatives of carbazole dissolve in nitrobenzene with a dark red colour, but no compound is formed at first. On heating for some hours at  $45-50^{\circ}$ , however, reaction takes place with formation of *9-p-nitrophenylcarbazole*, crystallising in yellow spangles with a green reflex, m. p.  $212^{\circ}$ ; *picrate*, garnet-red needles. The oxygen required for the reaction is provided by excess of nitrobenzene. That the nitrobenzene has, contrary to its usual behaviour, reacted in the para-position, is shown as follows. The nitro-compound was reduced and the product diazotised and converted by Gattermann's method into chlorophenylcarbazole, which was proved to be identical with that obtained by heating potassium carbazole with *p*-chlorobromobenzene. Further, the aminophenylcarbazole gave with phthalic anhydride a phthalimide isomeric but not identical with that obtained by heating potassium carbazole with *m*-bromophthalanil.

*p*-Aminophenylcarbazole, from the nitro-compound, forms a resin; its *picrate* forms yellowish-brown needles, m. p.  $200^{\circ}$  (decomp.). *p*-Acetamidophenylcarbazole crystallises in colourless plates, m. p.  $237^{\circ}$ . *p*-Phthalimidophenylcarbazole forms colourless needles, m. p.  $210^{\circ}$ ; *m*-phthalimidophenylcarbazole, obtained in only small yield by heating potassium carbazole with *m*-bromophthalanil, forms brilliant, pale red spangles, m. p.  $216^{\circ}$ .

The diazo-compounds of *p*-aminophenylcarbazole are characterised by their stability in acids and their intense colour, orange in solution or in hydrated crystals, yellow when anhydrous. *9*-Phenylcarbazole-*p*-diazonium chloride,  $C_{12}H_8N \cdot C_6H_4 \cdot N_2Cl$ , and sulphate are soluble in a dilute acid solution at  $70^{\circ}$ , crystallising on cooling in long, silky needles; the *nitrate*, which has a remarkably slight solubility in water, forms a yellow, microcrystalline precipitate. The salts are rapidly decomposed by acetates and alkalis.

$\beta$ -Naphtholazophenylcarbazole,  $C_{12}H_8N \cdot C_6H_4 \cdot N \cdot N \cdot C_{10}H_6 \cdot OH$ , forms garnet-red needles, m. p.  $230^\circ$ ; 9-p-Chlorophenylcarbazole forms small, pale yellow crystals, m. p.  $146^\circ$ ; 9-p-cyanophenylcarbazole, obtained by acting on the diazonium salt with cuprous cyanide, forms pale yellow crystals, m. p.  $165^\circ$ . Azophenylcarbazole,  $C_{12}H_8N \cdot C_6H_4 \cdot N \cdot N \cdot C_6H_4 \cdot C_{12}H_8N$ , obtained by partial reduction of *p*-nitrophenylcarbazole with zinc in acid solution, forms orange spangles, m. p.  $277^\circ$ .

*p*-Nitrophenylcarbazole is destroyed by concentrated sulphuric acid, but when treated with a mixture of sulphuric and chloro-sulphonic acids in nitrobenzene suspension it gives a crystalline sulphonic acid, green needles. When reduced, this gives an amino-sulphonic acid which, when diazotised and coupled with naphthols, yields red dyes inclined to violet. The colour obtained with  $\beta$ -naphthol gives a particularly brilliant barium lake.

By nitrating *p*-nitrophenylcarbazole in nitrobenzene suspension a dinitrophenylcarbazole, small, yellow crystals, m. p.  $274^\circ$ , is obtained. The second nitro-group is probably in the 3-position in the carbazole nucleus. The alcoholic solution of the diaminophenylcarbazole prepared from this shows a vivid blue fluorescence; its diacetyl derivative forms a white, crystalline powder, m. p.  $274^\circ$ . Nitration of *p*-acetamidophenylcarbazole gave a *p*-acetamidophenyl-dinitrocarbazole, yellow crystals, m. p.  $234^\circ$ ; it is probably the 3:6-derivative. When hydrolysed it gives *p*-aminophenyl-dinitrocarbazole, m. p.  $320^\circ$ . 9-*m*-Nitrotolylcarbazole, obtained by the action of *m*-nitrotoluene on potassium carbazole, is a yellow substance, m. p.  $138^\circ$ . E. H. R.

Condensation Products of Phenylhydroxylamine with Hydroxymethylene Compounds and Carbinols. IV. Hydroxymethylenephenylacetic Ester and Hydroxymethylenbenzylcyanide with Phenylhydroxylamine. H. RUPE and J. GRÜNHOFF (*Helv. Chim. Acta*, 1923, 6, 102—110; cf. A., 1921, i, 425; 1922, i, 448, 449).—Ethyl  $\alpha$ -hydroxymethylenephenylacetate condenses in the normal way with phenylhydroxylamine, but the direct product cannot be isolated as it at once loses alcohol, forming

the diphenylisooxazolone,  $\begin{array}{c} \text{CPh} \cdot \text{CH} \\ \text{CO} \text{---} \text{O} \end{array} > \text{NPh}$ , white needles, m. p.  $175^\circ$ .

The substance quickly turns yellow in the light; it dissolves in sulphuric acid with an intense blue colour, turned dark green by ferric chloride. The same compound is obtained from methyl  $\alpha$ -hydroxymethylenephenylacetate. In chloroform solution, the isooxazolone combines with bromine to form a dibromide, white, glistening leaflets, m. p. about  $180^\circ$ ; the compound cannot be recrystallised, as it immediately loses hydrogen bromide, forming

diphenylbromoisooxazolone,  $\begin{array}{c} \text{CPh} \cdot \text{CBr} \\ \text{CO} \text{---} \text{O} \end{array} > \text{NPh}$ , which has no definite m. p., but decomposes at  $164\text{--}166^\circ$ . When the diphenylisooxazolone is warmed with alcoholic potassium hydroxide, the ring is opened, with formation of trans- $\beta$ -phenylhydroxylaminomethylene-

*phenylacetic acid*, small, glistening, pyramidal crystals, m. p. 135°. This forms a grey, crystalline *silver* salt, and an *ethyl* ester, m. p. 75°. The fact that this ester is quite stable and cannot be converted into the isooxazolone is taken as evidence that it is the *trans*-form; it follows that the product obtained by the action of phenylhydroxylamine on ethyl hydroxymethylenephénylacétate, which immediately gives the isooxazolone, is the *cis*-form. When the above *trans*- $\beta$ -phenylhydroxylaminomethylenephénylacetic acid is heated above its m. p., it loses carbon dioxide, forming  $\beta$ -phenyl- $\beta$ -styrylhydroxylamine (Rupe and Wittwer, A., 1922, i, 448), which forms a somewhat unstable *dibromide*, small, white needles, m. p. 125°.

Hydroxymethylenephénylacetonitrile condenses with phenylhydroxylamine to give *phenyl- $\beta$ -cyanostyrylhydroxylamine*,  $\text{CN}\cdot\text{CPh}\cdot\text{CH}\cdot\text{NPh}\cdot\text{OH}$ , golden-yellow needles, m. p. 155°. Attempts to hydrolyse the nitrile to an acid were unsuccessful. Hydroxymethylenephénylacetonitrile condenses with aniline to form an *anilino*-derivative,  $\text{NHPh}\cdot\text{CH}\cdot\text{CPh}\cdot\text{CN}$ , white needles, m. p. 156°; with phenylhydrazine to a *phenylhydrazino*-derivative, white needles, m. p. 155–156°; and with *p*-aminophenol to form a *p*-hydroxyanilino-derivative, greyish-green needles, m. p. 150°. The last forms a *copper* salt,  $(\text{C}_{15}\text{H}_{11}\text{ON}_2)_2\text{Cu}$ , a nearly black powder.

E. H. R.

**The Interaction of Aliphatic Alcohols and  $\beta$ -Dibromopropylthiocarbimide.** RAYMOND M. HANN (*J. Amer. Chem. Soc.*, 1923, 45, 482–486).—Dixon (T., 1892, 61, 545; 1895, 67, 564; 1896, 69, 22) records the formation of 5-bromo-2-alkyloxy-4:6-dihydro-1:3-thiazines by the action of aliphatic alcohols on dibromopropylthiocarbimide. Gabriel (A., 1906, i, 889) considered these compounds to be 2-alkyloxy-5-bromomethyl- $\Delta^2$ -thiazolines. From a consideration of the reaction of *n*-butyl and isopentyl alcohols with the thiocarbimide and from a crystallographic study of the products, the author is of the opinion that the product formed in every case, regardless of the aliphatic alcohol used, is 2-hydroxy-5-bromomethyl- $\Delta^2$ -thiazoline, m. p. 95–96°. Secondary alcohols appear to react similarly. W. G.

**Halogenated Derivatives of Ketodihydro-1:4-benzthiazines and the Products of their Transformations. Conversion of Thiazine into Thiazole Compounds.** K. ZAHN (*Ber.*, 1923, 56, [B], 578–587).—Ketodihydro-1:4-benzthiazines react readily with halogens to yield mono- and di-substituted derivatives, in which the halogen atoms are highly reactive. In the case of the dichloro-compounds, there is a remarkable tendency for the thiazine to contract to the thiazole ring.

The monohalogenated derivatives are obtained by the action of the requisite quantity of bromine, sulphuryl chloride, or gaseous chlorine on a solution of the thiazine in the necessary amount of boiling benzene. 2-Bromo-3-keto-2:3-dihydro-1:4-benzthiazine,  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{NH}\cdot\text{CO} \\ \diagup \quad \diagdown \\ \text{S} \quad \text{CHBr} \end{smallmatrix}$ , colourless crystals, decomp. about 220° after

previous darkening; 2-chloro-3-keto-2:3-dihydro-1:4-benzthiazine, decomp.  $215^{\circ}$ ; 2:7-dichloro-3-keto-5-methyl-2:3-dihydro-1:4-benzthiazine, decomp. about  $245^{\circ}$  after darkening at  $200^{\circ}$ , and 2-chloro-3-keto-2:3-dihydro- $\alpha$ -naphththiazine, gradual decomp. above  $200^{\circ}$ , are described. When boiled with the requisite alcohol, the halogenated compounds exchange the halogen atom for the alkoxy-group. The following compounds are obtained in this manner: 2-methoxy-3-keto-2:3-dihydro-1:4-benzthiazine, almost colourless leaflets, m. p.  $188-189^{\circ}$ ; 2-ethoxy-3-keto-2:3-dihydro-1:4-benzthiazine, colourless crystals, m. p.  $168-169^{\circ}$ ; 7-chloro-2-methoxy-3-keto-5-methyl-2:3-dihydro-1:4-benzthiazine, pale brown prisms, m. p.  $189-190^{\circ}$ , and the corresponding ethoxy-derivative, colourless needles, m. p.  $197^{\circ}$ ; 2-methoxy- and 2-ethoxy-3-keto-2:3-dihydro- $\alpha$ -naphththiazine, prisms, m. p.  $223-224^{\circ}$ , and lustrous leaflets, m. p.  $208-209^{\circ}$ , respectively. These compounds are soluble in alkali hydroxide solutions with the formation of salts of the enolic forms which, however, could not be isolated. 2-Methoxy-3-keto-2-methyl-2:3-dihydro-1:4-benzthiazine, long, colourless needles, m. p.  $80-81^{\circ}$ , is prepared by the action of sodium hydroxide and methyl sulphate on the 2-methoxy-compound. 2-Acetoxy-3-keto-2:3-dihydro-1:4-benzthiazine, colourless, prismatic crystals, m. p.  $172-173^{\circ}$ , is obtained by the action of sodium acetate dissolved in glacial acetic acid on the 2-chloro-derivative; it is converted by sulphuric acid in the presence of ethyl alcohol into 2-ethoxy-3-keto-2:3-dihydro-1:4-benzthiazine and by concentrated sulphuric acid at about  $50^{\circ}$  into the ether,  $(\text{C}_6\text{H}_4 \begin{smallmatrix} \text{NH}\cdot\text{CO} \\ \text{S}-\text{CH}_2 \end{smallmatrix})_2\text{O}$ ,

a colourless powder, decomp. above  $300^{\circ}$ .

The following dichloro-derivatives are prepared by the gradual addition of sulphuryl chloride to a solution of the requisite thiazine in nitrobenzene and subsequently heating the mixture at about  $60^{\circ}$  until hydrogen chloride ceases to be evolved: 2:2-dichloro-3-keto-2:3-dihydro-1:4-benzthiazine, colourless needles, m. p.  $195-196^{\circ}$ ; 2:2:7-trichloro-5-methyl-3-keto-2:3-dihydro-1:4-benzthiazine, m. p.  $205-206^{\circ}$ ; 2:2-dichloro-3-keto-2:3-dihydro- $\alpha$ -naphththiazine, a pale yellow, crystalline powder, decomp. about  $240^{\circ}$  after previous darkening. Cautious treatment of the dichloro-compounds with methyl alcohol leads to the isolation of 2:2-dimethoxy-3-keto-2:3-dihydro-1:4-benzthiazine, colourless crystals, m. p.  $129-130^{\circ}$ ; 7-chloro-2:2-dimethoxy-3-keto-2:3-dihydro-1:4-benzthiazine, prisms, m. p.  $203-204^{\circ}$ , and 2:2-dimethoxy-3-keto-2:3-dihydro- $\alpha$ -naphththiazine, pale yellow prisms, m. p.  $171-172^{\circ}$ , whereas under more drastic treatment methyl benzthiazole-2-carboxylate,  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{N} \\ \text{S} \end{smallmatrix} \text{C} \cdot \text{CO}_2\text{Me}$ , and methyl  $\alpha$ -naphththiazole-2-carboxylate, needles, m. p.  $119^{\circ}$ , are produced. Boiling ethyl alcohol transforms the dichloroketothiazine into ethylbenzthiazole-2-carboxylate, m. p.  $70-71^{\circ}$ . Ethyl 6-chloro-4-methylbenzthiazole-2-carboxylate crystallises in colourless needles, m. p.  $97-98^{\circ}$ ; the corresponding amide, colourless leaflets, m. p.  $250-251^{\circ}$ , and acid, m. p.  $140^{\circ}$ , are described. Ethyl  $\alpha$ -naphththiazole-

carboxylate forms pale yellow needles, m. p. 129—130° (amide, n. p. 253—254°; corresponding acid, m. p. 140°).

2:2-Dichloro-3-keto-2:3-dihydro-1:4-benzthiazine is converted by cold concentrated sulphuric acid or, preferably, by boiling glacial acetic acid into 2:3-diketodihydro-1:4-benzthiazine,

$\text{H}_2\text{N} \begin{array}{c} \text{NH} \cdot \text{CO} \\ \diagup \quad \diagdown \\ \text{S} \quad \text{CO} \end{array}$ , pale yellow prisms, m. p. 250° (decomp.). The

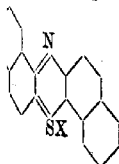

liketone is converted by dilute alkali hydroxide solutions into  $\alpha$ -thiolphenyloxamic acid,  $\text{SH} \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{CO} \cdot \text{CO}_2\text{H}$ , and finally into  $\alpha$ -aminophenylmercaptan and oxalic acid. It is transformed by aniline into benzthiazole-2-carboxyanilide, m. p. 157—158°, and by phenylhydrazine into benzthiazole-2-carboxyphenylhydrazide, pale yellow needles or coarse crystals, m. p. 220—222° after previous softening. 7-Chloro-2:3-diketo-5-methyldihydro-1:4-benzthiazine, n. p. 255° (decomp.), and 2:3-diketodihydro- $\alpha$ -naphthathiazine, yellow needles, decomp. 315°, are described.

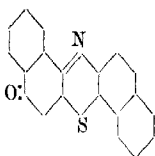

The dichloroketothiazines react with great readiness with amines, hydrazines, and phenylhydrazine. Thus, 2:2-dichloro-3-keto-2:3-dihydro-1:4-benzthiazine and aniline yield 2:3-diketodihydro-1:4-benzthiazine-2-anil, pale yellow, lustrous leaflets, m. p. 254—256°, which is converted by boiling alcohol into benzthiazole-2-carboxyanilide, m. p. 157—158°. In a similar manner, 7-chloro-5-methyldiketodihydro-1:4-benzthiazine-2-anil, golden-yellow leaflets, m. p. 247—248°, gives 6-chloro-4-methylbenzthiazole-2-carboxyanilide, colourless needles, m. p. 140—141°, and diketodihydro- $\alpha$ -naphthathiazine-2-anil, m. p. 290—292°, yields  $\alpha$ -naphthathiazole-2-carboxyanilide, colourless needles, m. p. 202—203°. 2:3-Diketodihydro-1:4-benzthiazine-2-phenylhydrazone crystallises in lustrous leaflets, m. p. 270—272° (decomp.); the corresponding zine is an orange-red powder.

2:2-Dichloro-3-keto-2:3-dihydro-1:4-benzthiazine is transformed by oxythionaphthen into the dye,  $\text{NH} \cdot \text{CO} \begin{array}{c} \text{NH} \cdot \text{CO} \\ \diagup \quad \diagdown \\ \text{C}_6\text{H}_4 \cdot \text{S} \quad \text{C} \cdot \text{C} \quad \text{CO} \\ \diagdown \quad \diagup \\ \text{S} \quad \text{CO} \end{array} \text{C}_6\text{H}_4$ , identical with the substance prepared by Herzog (A., 1920, i, 182) in a different manner. H. W.

**Azthionium Salts of the Naphthalene Series. II.** F. KREHMANN, ALFRED GRESSLY, WLADIMIR CHIFFÈRE, and MARIE RAMM (Ber., 1923, 56, [B], 649—654).—A continuation and amplification of previous work (cf. A., 1902, i, 566; 1921, i, 449).

Thio- $\alpha\beta$ -dinaphthylamine (cf. Gressly, Diss., Geneva, 1902) pale, orange-yellow prisms, m. p. 185—186°, is prepared by the action of sulphur on  $\alpha\beta$ -dinaphthylamine at a temperature not exceeding 240°. It is readily converted by the action of the requisite acid in the presence of a suitable oxidising agent into di- $\alpha\beta$ -naphthazthionium salts (annexed formula), of which the nitrate (+H<sub>2</sub>O), bronze crystals, the perchlorate, dark-violet crystals, and the picrate, dark-violet needles, are described in detail. Oxidation of thio- $\alpha\beta$ -dinaphthylamine by ferric chloride

leads to the formation of *di- $\alpha$ -naphthathiazine* (annexed formula), lustrous, dark brownish-red needles, m. p. 256—257°.

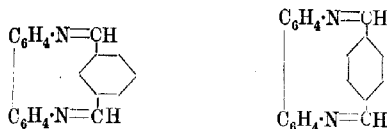

Thiodi- $\alpha$ -naphthylamine (cf. Kehrman and Dardel, A., 1922, i, 1064), m. p. 164—166°, in a capillary filled with carbon dioxide, is oxidised with great readiness in substance or in solution to  $\alpha$ -dinaphthathiazone (cf. A., 1902, i, 566). It is converted by acetic anhydride and anhydrous zinc chloride into the *acetyl* derivative,  $C_{20}H_{12}SNAc$ , colourless crystals, m. p. 214—215°. *Di- $\alpha$ -naphthazthionium nitrate*, brown needles, *perchlorate*, and *ferri chloride*,  $C_{20}H_{12}NSCl_4Fe$ , are described. The salt last mentioned is transformed by aniline hydrochloride and aniline in the presence of alcohol (80%) into *di- $\alpha$ -naphthathiazone* and *N-phenyldi- $\alpha$ -naphthathiazime*,  $PhN:C_{10}H_5 \begin{smallmatrix} \text{N} \\ \text{S} \end{smallmatrix} C_{10}H_5$ , small lustrous black crystals, m. p. 250—254°. *Di- $\alpha$ -naphthathiazime*,

yellowish-red crystals, gives a dark, violet-brown *chloroplatinate*, a bluish-violet *hydrochloride*, and a *perchlorate*. H. W.

**Influence of Substitution in the Components on Equilibrium in Binary Solutions. XXXVIII. The Binary Systems of Trinitrobenzene and Trinitrotoluene with the Three Isomeric Phenylenediamines.** ROBERT KREMANN and OTTO MAUERMANN (*Monatsh.*, 1923, 43, 315—320).—Both trinitrobenzene and trinitrotoluene form equimolecular compounds with each of the phenylenediamines. For 1:3:5-trinitrobenzene and *o*-phenylenediamine, the equimolecular compound melts at 163° (33.7% by weight of diamine), the eutectic between the compound and diamine occurs at 92° and 93% of the diamine, that between the compound and trinitrobenzene occurring at 108° and 3% of diamine. The six corresponding figures for the other binary systems examine are as follows: 2:4:6-Trinitrotoluene and *o*-phenylenediamine 97.5° (32.3%), 83° (57%), and 65° (9%). 1:3:5-Trinitrobenzene and *m*-phenylenediamine, 168° (33.7%), 45° (82%), and 105° (7%). 2:4:6-Trinitrotoluene and *m*-phenylenediamine, 105° (32.3%), 51.5° (90.5%), and 70° (6%). 1:3:5-Trinitrobenzene and *p*-phenylenediamine, 145.5° (33.7%), 106° (64%), and 101.5° (9%). 2:4:6-Trinitrotoluene and *p*-phenylenediamine, 93° (32.3%), 88° (38%), and 64° (8%). The results fall in line with those previously obtained with dinitrobenzenes, taking into account the effect of third nitro-group (cf. A., 1919, ii, 54). E. E. T.

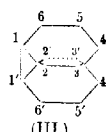

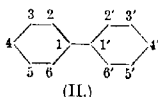

**The Structure of Benzidine.** ROGER ADAMS, J. E. BULLOCK and W. C. WILSON (*J. Amer. Chem. Soc.*, 1923, 45, 521—527).—It has been found that benzidine and certain of its derivatives condense readily with meta- and para-disubstituted benzene compounds, namely with terephthalaldehyde and isophthalaldehyde, to form substances which presumably have the structures

These compounds are characterised by their extreme insolubility and high melting or decomposition points. Their analysis is difficult, because the moment the combustion starts all the material is burned at once. Benzidine gives with *isophthalaldehyde* an amorphous compound,  $\text{C}_6\text{H}_4\text{N}=\text{CH}$   $\text{C}_6\text{H}_4\text{N}=\text{CH}$   $\text{C}_6\text{H}_4$ , with *terephthalaldehyde*

a yellow compound, and with *terephthalaldehyde monazine*, m. p.  $232^\circ$ , an orange-coloured compound. Dianisidine gives with *terephthalaldehyde* a yellowish-green compound. *Terephthalaldehyde dihydrazone*, m. p.  $165^\circ$ , was obtained by treating *terephthalaldehyde* with an excess of hydrazine hydrate.

From the above results it seems probable that the benzene rings in diphenyl derivatives are in motion within the limiting positions of the two possible Kaufer formulæ, I and III (cf. A., 1907, i, 307, 794), and the intermediate position, II, which is usually assigned to diphenyl.

W. G.

**Interaction of Formaldehyde and the Nitronaphthylamines.** GILBERT T. MORGAN and FRANK RAYMOND JONES (*J. Soc. Chem. Ind.*, 1923, 42, 92—97r).—The condensation of formaldehyde with each of the known nitronaphthylamines has been investigated in order to determine the effect of orientation of the substituent groups on the reactivity of the amines towards formaldehyde. The simplest form of condensation occurs with 1-nitro-3-naphthylamine, a methylene group becoming associated with two imino-groups from the primary nitroamine, producing *methylene-bis-1-nitro-3-naphthylamine*, which exists as two chromo-isomerides having the same melting point,  $222-223^\circ$ . The yellow isomeride, obtained as needles when the condensation is effected in glacial acetic acid, is transformed by solution in hot pyridine into the red form, which crystallises in hard, bright red prisms. With 4-nitro- $\alpha$ -naphthylamine, in cold glacial acetic acid, formaldehyde condenses to form 4:4'-dinitro-1:1'-diamino-2:2'-dinaphthylmethane, m. p.  $268-270^\circ$  (decomp.), in which the methylene group has probably entered the ring in the remaining reactive position 2. The product is soluble in hot nitrobenzene, from which it crystallises on cooling as yellow needles. An analogous condensation occurs, but less readily, with 2-nitro- $\alpha$ -naphthylamine,

leading to the production of 3:3'-*dinitro*-4:4'-*diamino*-1:1'-*dinaphthylmethane*, m. p. 299—301° (decomp.). The product dissolves readily in nitrobenzene, from which it crystallises in fine, silky, voluminous, rectangular, golden-yellow prisms. With the heteronuclear nitronaphthylamines, the condensations are more complicated and comparable with the reactions arising in the case of the unsubstituted naphthylamines (Morgan, T., 1898, 73, 536; Senier and Goodwin, 1902, 81, 288; Möhlau and Haase, A., 1903, i, 118, 126). The condensation of 5-nitro- $\beta$ -naphthylamine with formaldehyde in cold alcohol probably results in the production of *methylenebis*-5-nitro- $\beta$ -naphthylamine and 5:5'-*dinitro*-2:2'-*diamino*-1:1'-*dinaphthylmethane*, m. p. 233—235°. The methylene base, the primary condensation product, was not isolated in a state of purity, but the succeeding products were obtained separately by effecting the condensation in alcohol in the presence of mineral acid. On prolonged heating, 5:5'-*dinitro*-2:2'-*diamino*-1:1'-*dinaphthylmethane* was further condensed to the corresponding dihydronaphthacridine, which by aerial oxidation was converted into 4:10-*dinitrodinaphthacridine*. Experiments with 8-nitro- $\beta$ -naphthylamine indicate that, in position 8, the nitro-group appears to exert steric hindrance on the entry of the methylene radicle into the ring, so that the primary condensation product, *methylenebis*-8-nitro- $\beta$ -naphthylamine, m. p. 178°, appears in alcoholic solution, but in alcohol acidified with hydrochloric acid the reaction proceeds to the production of a small yield of 8:8'-*dinitro*-2:2'-*diamino*-1:1'-*dinaphthylmethane*. The behaviour of 8-nitro- $\alpha$ -naphthylamine is similar to that of the corresponding  $\beta$ -naphthylamine. In glacial acetic acid, 5:5'-*dinitro*-4:4'-*diamino*-1:1'-*dinaphthylmethane* is produced and separates out with three molecular proportions of formaldehyde, as a pale yellow, crystalline powder. The yield is almost quantitative, and the m. p. of the additive compound is 172—173°. 5-Nitro- $\alpha$ -naphthylamine resembles  $\alpha$ -naphthylamine in condensing with formaldehyde to give ill-defined and inseparable products. Evidence was obtained of the presence in the condensed products of a hydrolysable methylene base and a base of the dinaphthacridine series. J. S. G. T.

**Action of the Oxides and the Oxy-acids of Nitrogen on the Phenylcarbamides.** HUGH RYAN and PETER K. O'TOOLE. (*Proc. Roy. Dublin Soc.*, 1923, 17, 139—155; cf. this vol., 321, 322, 323).—The nitration of phenylcarbamide, *s*-diphenylcarbamide, *as*-diphenylcarbamide, and triphenylcarbamide has been systematically investigated. In regard to ease of nitration, the phenylcarbamides resemble the corresponding phenylurethanes; they are much less easily nitrated than the analogous phenyl nitrosoamines.

When treated with cold dilute nitric acid, phenylcarbamide forms its nitrate; *s*- and *as*-diphenylcarbamides are unchanged; and triphenylcarbamide yields a *dinitrotriphenylcarbamide*, yellow prisms, m. p. 190—191°, and a *trinitrotriphenylcarbamide*, slightly yellow leaves, m. p. 205—206°. Under similar conditions, but in

carbon tetrachloride suspension, phenylcarbamide forms the nitrate, *p*-nitro-, and 2:4-dinitro-derivatives; *s*-diphenylcarbamide is nitrated to the 4-nitro-, 4:4'-dinitro-, and 2:4:2':4'-tetranitro-derivatives; from *as*-diphenylcarbamide no pure compound is obtained; triphenylcarbamide gives the above dinitro- and trinitro-compounds, and a *pentanitrotriphenylcarbamide*, yellow prisms, decomp. 180°, m. p. 235—236° (decomp.). Cold fuming nitric acid converts phenylcarbamide into 2:4-dinitrophenylnitrocarbamide; *s*-diphenylcarbamide forms the 4:4'-dinitro- and 2:4:2':4'-tetranitro-derivatives; whilst both *as*-diphenylcarbamide and triphenylcarbamide give 2:4:2':4'-tetranitrodiphenylamine.

In cold glacial acetic acid solution, nitrous acid converts phenylcarbamide into nitrosophenylcarbamide, whilst *as*-diphenylcarbamide and triphenylcarbamide are apparently not acted on. *s*-Diphenylcarbamide forms *dinitroso-s-diphenylcarbamide*, prismatic needles, decomp. 103°, which is converted on being boiled with alcohol into *s*-diphenylcarbamide, gives 2:4:2':4'-tetranitro-*s*-diphenylcarbamide on direct nitration, and with nitric acid in acetic acid solution gives 4:4'-dinitro-*s*-diphenylcarbamide. A synthesis of the latter by the condensation of 1 mol. of carbamide with 2 mols. of *p*-nitroaniline is described. The same dinitroso-compound is produced by the action of nitrous fumes in acetic acid solution on *s*-diphenylcarbamide, but by the prolonged action of nitrogen peroxide, 4:4'-dinitrodiphenylcarbamide is produced. Phenylcarbamide is converted by nitrous fumes in carbon tetrachloride suspension into *o*-nitrophenol and *p*-nitrophenol. *as*-Diphenylcarbamide is decomposed by nitrogen peroxide at the ordinary temperature, forming 4:4'-dinitrodiphenylnitrosoamine; triphenylcarbamide under similar conditions gives the trinitrotriphenylcarbamide (above).

W. S. N.

**Action of the Oxides and the Oxy-acids of Nitrogen on Phenylmethylcarbamide.** HUGH RYAN and MICHAEL J. SWEENEY (*Proc. Roy. Dublin Soc.*, 1923, 17, 157—162; cf. preceding abstract).—No nitro-derivatives of phenylmethylcarbamide have been obtained, because nitrous acid converts phenylmethylcarbamide into methylaniline; nitro-derivatives of the latter are in all cases isolated.

Nitrous acid converts phenylmethylcarbamide into gaseous nitrogen peroxide converts phenylmethylcarbamide into 4:6-trinitrophenylmethylnitrosoamine (tetryl), but in solution 4:6-trinitrophenylmethylnitrosoamine, 2:4-dinitro-, and 2:4:6-trinitromethylaniline are successively produced. In the presence of carbamide nitrate, nitric acid has little, if any, action on phenylmethylcarbamide, but in the presence of nitrous acid, phenylmethylnitrosoamine, 4-nitrophenylmethylnitrosoamine, 2:4-dinitromethylaniline, 2:4:6-trinitromethylaniline, and tetryl are formed.

Tetryl may readily be obtained pure by the nitration of phenylmethylcarbamide or of phenylmethylnitrosoamine.

W. S. N.

**Thiocarbamide Ethers.** F. B. DAINS and W. C. THOMPSON (*Univ. Kansas Sci. Bull.*, 1922, 13, 118—120; cf. Will, A., 1881, 905; Will and Bielschowski, A., 1882, 1090; Evers, A., 1888, 600; Foerster, A., 1888, 944).—Substituted thiocarbamides form additive products with alkyl halides, the free thiocarbamide ethers being prepared from these salts by the action of alkalis:

When 15 g. of thiocarbamilide and 10 g. of propyl iodide are heated for one hour on the steam-bath, a light brown, viscous liquid separates and solidifies on cooling. When crystallised from alcohol, colourless *N*-diphenyl-*S*-propylthiocarbamide hydriodide, m. p. 103°, is obtained; the free base forms needles, m. p. 61.5°. Butyl iodide and thiocarbamilide yield *N*-diphenyl-*S*-butylthiocarbamide hydriodide, m. p. 122°, which could not be crystallised, but was well washed with ethyl ether; the corresponding base is a colourless oil. Propyl iodide and di-*p*-tolylthiocarbamide give *N*-di-*p*-tolyl-*S*-propylthiocarbamide hydriodide, m. p. 165° (base, fine, white needles, m. p. 99°). The corresponding butyl derivative is a thick, colourless liquid (hydriodide, m. p. 145°). Di-*m*-xylylcarbamide and propyl iodide yield directly *N*-di-*m*-xylyl-*S*-propylphenylthiocarbamide, m. p. 113.5°. The unsymmetrical nature of the molecule did not prevent addition of the alkyl iodide, since methyl iodide and phenylbromophenylthiocarbamide yield *N*-phenyl-*p*-bromophenyl-*S*-methylthiocarbamide hydriodide, m. p. 152° (base, white needles, m. p. 79°); *N*-phenyl-*p*-bromophenyl-*S*-propylthiocarbamide hydriodide, a red oil (base, m. p. 84°), and *N*-phenyl-*p*-bromophenyl-*S*-butylthiocarbamide hydriodide, a thick oil (base, a viscid oil) were also prepared. When phenylthiocarbamide and butyl iodide are warmed together on a water-bath, a gummy mass is produced which on treatment with sodium carbonate yields *N*-phenyl-*S*-butylthiocarbamide, a heavy oil.

## CHEMICAL ABSTRACTS.

**The Presumed Reaction of 4 : 4'-Dipyridyl with Potassium Ferrocyanide.** J. P. WIBAUT and ELISABETH DINGEMANSE (*Rec. trav. chim.*, 1923, 42, 184—185).—It has been stated that 4 : 4'-dipyridyl gives a characteristic blue precipitate with potassium ferrocyanide (Anderson, *Annalen*, 1870, 78, 274; Weidel and Russo, A., 1883, 483), and Heuser and Stoehr obtained reddish-brown crystals which they assert, apparently without experimental evidence, to be 4 : 4'-dipyridyl ferrocyanide (A., 1892, 75). The authors have prepared the blue precipitate and found it to be Berlin-blue, whilst the reddish-brown crystals obtained in hydrochloric acid solution are now proved to be the dipyridyl ferrocyanide. The reaction, however, is not specific for 4 : 4'-dipyridyl.  
H. J. E.

**Fission of 4 : 4'-Dipyridyls by Cyanogen Halides.** W. KÖNIG [with G. EBERT and K. CENTNER] (*Ber.*, 1923, 56, [B], 751—758).—The action of cyanogen bromide and amines on 4 : 4'-dipyridyl has been investigated with the object of preparing pentamethin dyes.

4:4'-Dipyridyl 1-cyanobromide,  $C_5NH_4 \cdot C_5NH_4Br \cdot CN$ , or

is prepared by the addition of an ethereal solution of cyanogen bromide to 4:4'-dipyridyl dissolved in alcohol; the use of anhydrous materials and the exclusion of moisture are essential to the success of the preparation, the special apparatus for which is fully described in the original. The substance forms a pale brown precipitate which decomposes into dipyridyl and cyanogen bromide when heated. It gives salts with picric acid and sodium perchlorate. It is converted by aniline and subsequent treatment with sodium perchlorate, picric acid, or potassium iodide into the corresponding dipyridyl, salts of which the iodide,  $C_{20}H_{18}N_4I_2 \cdot H_2O$ , brownish-yellow leaflets which commence to sublime at  $65^\circ$ , is described in detail. The simultaneous action of cyanogen bromide and aniline on dipyridyl leads to the production of the dye

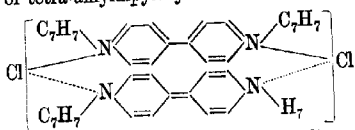

which is converted into 1:1'-diphenyl-4:4'-dipyridylium bromide; the corresponding perchlorate,  $C_{22}H_{18}O_8N_4Cl_2$ , pale, greenish-yellow needles, m. p.  $299^\circ$  (decomp.), the picrate,  $C_{34}H_{22}O_{14}N_8$ , slender, yellow needles, m. p.  $170^\circ$ , and the chloroferrate,  $C_{22}H_{18}N_4Cl_2Fe_3$ , small, yellow needles, m. p.  $210-215^\circ$ , are described. 1:1'-Diphenyl-4:4'-dipyridylium di-iodide is precipitated as a yellow, unstable polyhydrate which passes into the stable salt ( $+0.5H_2O$ ), small, dark red prisms.

The 1:1'-diphenyldipyridylium salts exhibit the "triphenylmethyl phenomenon" particularly distinctly when they are warmed with zinc dust and glacial acetic acid; the deep bluish-green coloration disappears immediately when the solutions are shaken with air, and the process may be repeated as long as unused zinc dust is present. The same change is observed in aqueous-alcoholic solution in the presence of hyposulphite, zinc dust, or ferrous sulphate, or in aqueous solution in the presence of free hydroxylamine; a merquinonoid compound appears to be thereby produced (cf. Emmert, A., 1922, i, 1064). A pure green coloration is caused by the addition of alkali hydroxide to aqueous solutions of 1:1'-diphenyldipyridylium salts; its formation is explained on the assumption that the ammonium base is partly converted into the pseudobase, which passes into a mixture of 1:1'-diphenyl-2:2'-dipyridone and 1:1'-diphenyl-2:2'-tetrahydro-4:4'-dipyridyl; the latter substance becomes tautomerised to the 4:4'-tetrahydro-compound which reacts with unchanged ammonium base to give a green, quinhydrone-like compound.

H. W.

**Quinhydrone-like Compounds of 1:1'-Dialkyldihydro-4:4'-dipyridyls.** BRUNO EMMERT and OTTO VARENKAMP (*Ber.*, 1923, 56, [B], 491-501).—In a previous communication (A., 1922, i, 1064), it has been shown that 4:4'-dipyridyl dibenzyl-iodide is reduced by 1:1'-dibenzyltetrahydro-4:4'-dipyridyl to

1:1'-dibenzylidihydro-4:4'-dipyridyl, which immediately unites with a second molecule of dipyridyl dibenzyl iodide to give a quinhydrone-like compound. More recently, Dimroth and Frister (this vol., i, 149) have isolated the parent substance of this quinhydrone, which they term dipyridylviolet chloride. In the present communication, this nomenclature is adopted, and a further series of tetra-alkyldipyridylviolet halides is described.

*Tetrabenzylidipyridylviolet chloride* (annexed formula), violet, oblique leaflets, m. p. about 190° (decomp.), when rapidly heated, is prepared by the action of an alcoholic solution of 1:1'-dibenzyltetrahydro-4:4'-dipyridyl on an equimolecular quantity of dipyridyl dibenzylchloride. It can be preserved during some days when exposed to air. It is extraordinarily sensitive to air if dissolved in acetic anhydride or glacial acetic acid, but much more stable in chloroform, acetone, aniline, or, particularly, in pyridine.

*Tetrabenzylidipyridylviolet bromide*, dark violet, oblique leaflets, is prepared in a similar manner. The substance is also prepared by the reduction of 4:4'-dipyridyl dibenzylbromide in alcoholic solution (90%) by zinc dust or magnesium powder, thus indicating that the blue colour observed during the treatment of dipyridyl dialkyl iodides with zinc dust is due to the quinhydrone, and not, as Weitz and König have supposed (A., 1922, i, 1186), to the halogen-free, 1:1'-dialkyl-4:4'-dipyridinium radicle.

[With VALENTIN DÖLLEIN.]—*Tetraisoamylidipyridylviolet iodide*, dark violet leaflets, with a metallic reflex, is prepared by the action of zinc dust on 4:4'-dipyridyl diisoamyl iodide.

4:4'-Dipyridyl dibenzylchloride is reduced by chromous chloride to tetrabenzylidipyridylviolet chloride; the corresponding bromide is produced in unsatisfactory yield by the action of phenylhydrazine on 4:4'-dipyridyl dibenzylbromide.

The semiquinonoid character of tetrabenzylidipyridylviolet bromide and iodide is further established by the observation that a molecular proportion of either substance dissolved in glacial acetic acid absorbs an atomic proportion of oxygen.

[With HEINRICH LUDWIG.]—2:6:2':6'-*Tetradimethylidipyridyl dibenzyl iodide*, obtained from its components at 150°, is isolated in a red, anhydrous and a yellow, hydrated form. It is converted by dibenzyltetrahydrodipyridyl into *tetrabenzylidipyridylviolet iodide*, dark bronze-brown, oblique leaflets, m. p. about 170°. 2:6-Dimethylpyridine benzyl iodide is prepared from its components at 130° (corresponding perchlorate, long needles, m. p. 141°); it is reduced by sodium amalgam to *dibenzyltetrahydrodi-2:6:2':6'-tetramethylpyridyl*, pointed prisms, m. p. 124°, after previous darkening.

[With GERHARD JUNGCK.]—Dimethyltetrahydrodicollidyl and dipyridyl dibenzyl iodide yield tetrabenzylidipyridylviolet iodide and methylocollidinium iodide. Collidinium methoperchlorate is

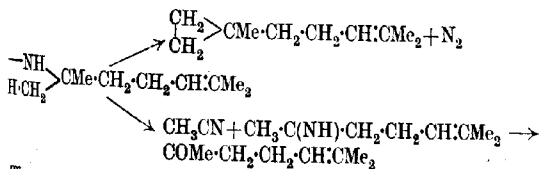

obtained by the action of silver nitrate dissolved in alcohol on 1:1'-dimethyltetrahydrodicollidyl and, after removal of the silver, addition of perchloric acid.

[With EBERHARD VOGT.]—By the introduction of a phenyl group in position 4, it was hoped to weaken the union of the  $\gamma$ -carbon atoms possibly to such an extent as to lead to the formation of the radicle. With this object, 4-phenylpyridine is converted into the corresponding *methiodide*, almost colourless crystals, which, however, is reduced by sodium amalgam and water to 4-phenyl-1-methyldihydropyridine, colourless needles, m. p.  $36^\circ$ , instead of the expected dipyrldyl derivative. H. W.

**The Conversion of Citral into the Hydrocarbon, C<sub>10</sub>H<sub>18</sub>, of the cycloPropane Series.** N. KISHNER (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 1—19; A., 1911, i, 1027; 1914, i, 129).—The hydrazone of citral is converted by distillation into the pyrazolone. The anomalous behaviour of citral in forming a semi-stable hydrazone, although it has a double bond in the  $\alpha\beta$ -position to the carbonyl group, which seems usually to preclude the formation of hydrazones, giving in their place pyrazolones, is explained as being due to the space configuration of the citral, which approaches that of ring compounds, these giving stable hydrazones. *Citralpyrazolone*,

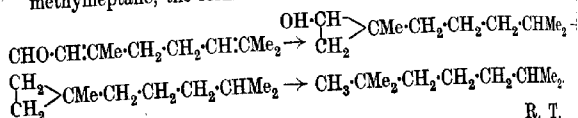

is obtained as an oil, b. p.  $122^\circ/12$  mm.,  $d_4^{20}$  0.9213,  $n_D^{20}$  1.4897, soluble in water, and very hygroscopic. The *phenylthiocarbamyl* compound,  $\text{NHPh}\cdot\text{CS}\cdot\text{N}_2\text{C}_{10}\text{H}_{17}$ , forms large prisms, m. p.  $51^\circ$ . The pyrazolone is unaffected by cold glacial acetic acid or by colduming hydrochloric acid, but on heating with the latter in a sealed tube at  $100^\circ$ , hydrazine hydrochloride is eliminated, and *p*-cymene obtained quantitatively. The *p*-cymene thus obtained is uncontaminated by other products, and this method is recommended for its preparation in a pure state. Citral itself gives the same product under these conditions, but the reaction is much slower, and it seems probable that the pyrazolone is converted directly into *p*-cymene, and not first into citral. The pyrazolone on distillation, in the presence of platinum catalyst, from alkali hydroxide, gives in the distillate, together with unchanged material, acetone, nitrile, methylheptanone, and 1-methyl-1-isohexylenylcyclopropane, C<sub>10</sub>H<sub>18</sub>, formed in the following way:

The hydrocarbon had b. p.  $160^\circ/735$  mm.,  $d_4^{20}$  0.7744,  $n_D^{20}$  1.4432. A structure was deduced from its oxidation products, acetone, a

ketone, and an acid. The ketone,  $\begin{matrix} \text{CH}_2 \\ | \\ \text{CH}_2 \end{matrix} > \text{CMe} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{CHMe}_2$ , has m. p. 14.5—15°, b. p. 222.5°/749 mm.,  $d_4^{20}$  0.9406,  $n_D^{20}$  1.4491 (*semi-carbazone*, m. p. 149—151°). The acid,  $\begin{matrix} \text{CH}_2 \\ | \\ \text{CH}_2 \end{matrix} > \text{CMe} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CO}_2\text{H}$ , has b. p. 219—222°/756 mm.,  $d_4^{15}$  0.9919,  $n_D^{15}$  1.4444, and gives an anilide, m. p. 126—127°. Further evidence of the structure of the hydrocarbon is given by its reduction products, obtained by the action of hydrogen in the presence of a platinum catalyst. This results in a mixture of three parts of 1-methyl-1- $\beta$ -methylpentyl-cyclopropane with five parts of a further reduction product,  $\beta\beta$ -trimethylheptane, b. p. 150.5—151.5°/748 mm.,  $d_4^{20}$  0.7215,  $n_D^{20}$  1.400. The reduction of the undistilled hydrazone, which has a citral-like structure, leads to the production of an isomeride of the latter,  $\beta$ -dimethyloctane. It is shown that the hydrocarbon obtained by Skita and Ritter (A., 1911, i, 272) by the Sabatier reduction of citral is not, as they stated, the  $\beta$ -dimethyloctane, but  $\beta\beta$ -trimethylheptane, the formation of which is thus explained:

R. T.

**Bromo-derivatives of 4-Methylglyoxaline.** FRANK LEE PYMAN and GEOFFREY MILLWARD TIMMS (T., 1923, 123, 494—503).

**4(5)-Nitroglyoxaline-5(4)-carboxylic Acid.** A. WINDAUS and W. LANGENBECK (*Ber.*, 1923, 56, [B], 683—686).—The acid (cf. Windaus and Opitz, A., 1911, i, 752; Mömer, A., 1918, i, 198; Z. *physiol. Chem.*, 1918, 103, 80; Fargher and Pyman, T., 1919, 115, 219) may be obtained readily by the condensation of 5(4)-nitro-4(5)-methylglyoxaline with aldehydes and oxidation of the products by potassium permanganate.

4(5)-Nitro-5(4)-methylglyoxaline condenses with benzaldehyde in the presence of piperidine at 150—160° to yield 4(5)-nitro-5(4)-styrylglyoxaline,  $\begin{matrix} \text{N} \cdot \text{C}(\text{NO}_2) \\ | \\ \text{CH} - \text{NH} \end{matrix} > \text{C} \cdot \text{CH} \cdot \text{CHPh}$ , golden-yellow leaflets,

decomp. above 220°; the corresponding compound from anisaldehyde crystallises in orange-yellow needles, m. p. about 296° (decomp.). The styryl derivative is converted by potassium permanganate in cold alkaline solution almost quantitatively into 4(5)-nitroglyoxaline-5(4)-carboxylic acid, almost colourless prisms m. p. above 300° (decomp.). The acid loses carbon dioxide when heated at 150° and yields 4(5)-nitroglyoxaline. *Methyl-4(5)-nitroglyoxaline-5(4)-carboxylate* crystallises in colourless, lustrous leaflets, m. p. 212—213°; 4(5)-nitroglyoxaline-5(4)-carboxamide forms almost colourless needles or prisms, m. p. 291°. Methyl nitroglyoxalinecarboxylate is hydrogenated in absolute alcohol

solution in the presence of palladium black to the corresponding amino-ester, which is characterised as the *picrate*,  $C_{11}H_{10}O_6N_4$ , yellow needles, m. p.  $235^\circ$  (decomp.), and *hydrochloride*,  $C_8H_8O_2N_2Cl$ , m. p. about  $210^\circ$  (decomp.). 4(5)-Aminoglyoxaline-5(4)-carboxamide is prepared in a similar manner, and is characterised as the *picrate*,  $C_{10}H_8O_6N_4$ , small prisms, decomp. about  $240^\circ$ , and the *hydrochloride*,  $C_8H_7ON_2Cl$ .  
H. W.

**Bromination of Glyoxaline-4-carboxyanilide.** HAROLD KING and WILLIAM OWEN MURCH (T., 1923, 123, 621—629).

**Some New Unsymmetrical Dialkylbarbituric Acids. I. Ethylalkylbarbituric Acids.** M. TIFFENEAU (Bull. Soc. chim., 1923, [iv], 33, 183—188).—The preparation and properties of some new ethylalkylbarbituric acids are described. *Ethyl-n-butylbarbituric acid* forms slender needles, m. p.  $128^\circ$ . It was obtained by condensing carbamide with *ethyl ethyl-n-butylmalonate*, b. p.  $240$ — $245^\circ/770$  mm. This ester on hydrolysis and subsequent heating of the free acid gives  $\alpha$ -ethylhexoic acid, b. p.  $220$ — $224^\circ/770$  mm. Its *chloride* boils at  $85$ — $90^\circ/20$  mm., and its carbamide,  $\alpha$ -ethylhexoylearbamide, melts at  $159^\circ$ . *Ethylisobutylbarbituric acid*, needles, m. p.  $174^\circ$ , was prepared in the usual way from *ethyl ethylisobutylmalonate*, b. p.  $234$ — $240^\circ/760$  mm. This ester on saponification gave *ethylisobutylmalonic acid*, m. p.  $107$ — $108^\circ$ , which by loss of carbon dioxide gave  $\gamma$ -methyl- $\alpha$ -ethylvaleric acid, b. p.  $115^\circ/20$  mm. The *chloride* of this acid boils at  $168$ — $171^\circ$  and the *amide* melts at  $89^\circ$ . Both the butyl- and isobutyl-ethylbarbituric acids are about three times as active as veronal. *Ethylisoamylbarbituric acid* forms leaflets, m. p.  $154$ — $155^\circ$ . It is nearly as powerful a hypnotic as the butyl derivatives, but acts much more rapidly, and its effect is correspondingly less prolonged. It is obtained from *ethyl ethylisoamylmalonate*, b. p.  $248$ — $253^\circ$ . *Ethylisoamylmalonic acid* melts at  $116$ — $118^\circ$ , and is converted on heating into  $\delta$ -methyl- $\alpha$ -ethylhexoic acid, b. p.  $228$ — $232^\circ$ . The *chloride* of this acid boils at  $188$ — $192^\circ$ , and the *amide* melts at  $106$ — $108^\circ$ . To complete the series of alkylbarbituric acids, *di-n-butylbarbituric acid* was prepared. It melts at  $153^\circ$ .

G. F. M.

**Some New Unsymmetric Dialkylbarbituric Acids. II. Homologous Series.** CH. SOMMAIRE (Bull. Soc. chim., 1923, [iv], 33, 189—195).—The preparation of the following ethyl dialkylmalonates, free dialkylmalonic acids, and the dialkylacetic acids derived from them, and also the dialkylbarbituric acids obtained by condensation with carbamide, are described: *Ethyl methyl-n-butylmalonate*, b. p.  $235$ — $241^\circ$ ; *methyl-n-butylmalonic acid*, m. p.  $98^\circ$ ; *methyl-n-butylbarbituric acid*, m. p.  $181^\circ$ ; *ethyl propyl-n-butylmalonate*, b. p.  $248$ — $253^\circ$ ; *propylbutylmalonic acid*, m. p.  $150$ — $151^\circ$ ;  $\alpha$ -propylhexoic acid,  $d_4^{20}$  0.914, its *chloride*, b. p.  $192$ — $195^\circ/767$  mm., and *amide*, m. p.  $122$ — $123^\circ$ ; *propylbutylbarbituric acid*, m. p.  $153^\circ$ ; *butylisobutylbarbituric acid*, m. p.  $153^\circ$ ; *ethyl methylisobutylmalonate*, b. p.  $232$ — $236^\circ$ ; *methylisobutylbarbituric*

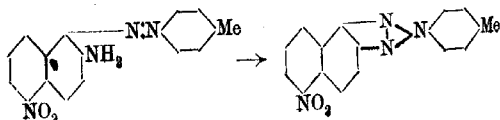

acid, m. p. 195°;  $\gamma$ -methyl- $\alpha$ -propylvaleramide, m. p. 121°; propylisobutylbarbituric acid, m. p. 164—165°; ethyl methylisocamylmalonate, b. p. 242—247°; methylisocamylmalonic acid, m. p. 131—132°;  $\alpha$ , $\delta$ -dimethylhexoic acid, b. p. 120—130°/15 mm., giving a chloride, b. p. 69—71°/15 mm., and an amide, m. p. 103°; methylisocamylbarbituric acid, m. p. 187°; ethyl propylisocamylmalonate, b. p. 254—259°/76 mm.; propylisocamylmalonic acid, m. p. 143°;  $\delta$ -methyl- $\alpha$ -propylhexoic acid, b. p. 238—245°, giving a chloride, b. p. 200—205°; and an amide, m. p. 117—118°; propylisocamylbarbituric acid, m. p. 134°; ethyl heptylmalonate, b. p. 273—275°; ethyl ethylheptylmalonate, b. p. 168—171°/15 mm.; ethyl heptylbarbituric acid, m. p. 118—119°. The maximum hypnotic activity observed by Tiffeneau (preceding abstract) with the C<sub>10</sub> and C<sub>11</sub> members of the barbituric acid series was not exceeded by any of the above homologues. The activity of the higher members seems to depend on the solubility, which diminishes rapidly with increasing number of carbon atoms. The influence of a branched chain on the solubility in water is anomalous. In the methyl series, the isobutyl group does not change the solubility as compared with the butyl group, in the ethyl series it somewhat reduces the solubility, in the propyl series it increases it slightly, and in the butyl series it considerably increases it. In all cases, an increasing number of carbon atoms decreases the solubility, with the sole exception of the methyl- and ethyl-butylbarbituric acids, the solubility of the former being only about one-half of that of the latter.

G. F. M.

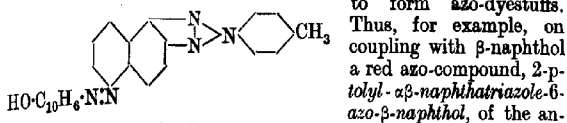

**Constitution of Natural Muscarine.** S. SCILBA (*Atti R. Accad. Lincei*, 1922, [v], 31, ii, 518—520).—In order to ascertain if muscarine has the aldehydic structure usually assigned to it, the author treated, with the Angeli-Rimini aldehyde reagent, an extract prepared from *Agaricus muscarius*; no hydroxamic acid was, however, obtained, although the extract showed distinctly the physiological effect of muscarine. To obtain a definite decision on this question, the preparation of a larger quantity of muscarine is contemplated.

T. H. P.

**Preparation of a Series of Substituted  $\alpha$ -Naphthylamines and of the Dyes derived from them.** L. B. HOLLIDAY & Co., LTD., and GILBERT THOMAS MORGAN (Brit. Pat. 191797).—Triazoles derived from  $\alpha$ -naphthylamine are obtained from 5-nitro- $\beta$ -naphthylamine, which is the main product of the dehydration of  $\beta$ -naphthylamine nitrate, by coupling with diazotised *p*-toluidine, whereby 1-*p*-toluenazo-5-nitro- $\beta$ -naphthylamine is obtained, and this compound on oxidation with chromic acid is converted into 6-nitro-2-*p*-tolyl- $\alpha$ - $\beta$ -naphthatriazole, according to the following scheme:

On reduction with stannous chloride, the corresponding 6-amino-1-p-tolyl- $\alpha\beta$ -naphthatriazole is formed. A similar series of reactions may be carried out with 8-nitro- $\beta$ -naphthylamine. The amino-triazoles are capable of conversion into diazo-derivatives which couple readily with phenols, and the more reactive aromatic amines to form azo-dyestuffs.

Thus, for example, on coupling with  $\beta$ -naphthol a red azo-compound, 2-p-tolyl- $\alpha\beta$ -naphthatriazole-6-azo- $\beta$ -naphthol, of the an-

nexed constitution is obtained.

The amino-triazoles can also be coupled with other diazo-compounds, for example, a brownish-red dyestuff, 7-p-nitrobenzene-azo-6-amino-2-p-tolyl- $\alpha\beta$ -naphthatriazole is obtained from the above amino-triazole and diazotised *p*-nitroaniline. The conversion of this substance, by oxidation with chromic acid, into a bis-triazole derivative proves its constitution as an ortho-amino-azo-compound.

G. F. M.

**Adsorption of Uric Acid by Animal Charcoal, Suspensoid Colloids, and Proteins.** K. HARPUDER (*Z. ges. exp. Med.*, 1922, 29, 208—223; from *Chem. Zentr.*, 1923, i, 90—91).—The adsorption of uric acid by animal charcoal follows the ordinary equation,  $y/m = kc^{1/n}$ . The temperature coefficient of adsorption is negative and inappreciable. Adsorption is increased in the presence of hydrochloric acid, decreased in presence of moderate concentrations of alkalis; with higher concentrations of alkalis adsorption is increased. In the presence of large quantities of neutral salts, adsorption is increased. Addition of sodium urate to a colloidal solution of ferric hydroxide produces, first, a marked turbidity and then, with larger quantities of sodium urate, flocculation, the sodium urate being adsorbed by the colloidal ferric hydroxide. Casein in 0.1*N*-alkali solution does not adsorb a neutral urate. In 0.1*N*-acid solution, however, sorption takes place and separation of the urate by ultra-filtration is not possible. The fixation differs in some respects from normal adsorption. The flocculation of casein chloride by neutral salts is facilitated by addition of uric acid. This is due either to a widening of the isoelectric zone or to flocculation before the isoelectric point is reached. Casein in acid solution is flocculated by uric acid directly. 0.373 Millimol. of uric acid flocculate 100 c.c. of 0.75% casein solution in 0.005*N*-hydrochloric acid. The corresponding value for flocculation by sodium chloride is 16.45 millimol., and by sodium sulphate 0.21 millimol. Serum-globulin behaves like casein. The effect of sorption of uric acid on the stability of globulin is less marked than in the case of casein solutions. Albumins show very little sorption of uric acid, which, in consequence, has no effect on their stability. The sorption of uric acid by proteins is held to be governed by intensity of electrical charge and is not a simple adsorption. A purely electrical explanation is, however,

*p*\*

inadequate. Organ extracts from muscle, cartilage, and liver fix uric acid to varying extents, the greatest fixation being shown by liver extract, the least by cartilage extract. G. W. R.

**The Formation of By-products in Diazotisation by Witt's Method.** L. ELION (*Rec. trav. chim.*, 1923, 42, 145-183).—Diazotisation by Witt's method (A., 1909, i, 855) of six substituted anilines, all somewhat basic, showed that the reaction did not in any instance take place wholly in the normal manner. Five of the substances, 3:5-dibromo-4-aminobenzoic acid, 3:5-dibromo-4-aminobenzaldehyde, 3:5-dibromo-4-aminoacetophenone, 3:5-dichloro-4-aminobenzoic acid, 3:5-dibromo-2-aminobenzoic acid, yield, in addition to the anticipated product, a nitro-derivative, whilst the sixth, 3:5-dinitro-4-aminobenzoic acid, furnished a diazonium compound of such instability that it was decomposed by the addition of ice to its solution. The action of the nitric acid on the first four substances is to replace the group in the para-position to the amino-group by a nitro-group in a portion of the product: this takes place when the two ortho-positions with respect to the amino-group are occupied by bromine or chlorine, the groups replaced being carboxyl, acetyl, and the aldehyde group, respectively. In the case of 3:5-dibromo-2-aminobenzoic acid, the bromine atom in the para-position to the amino-group is replaced by the  $\text{NO}_2$ -group, whilst when nitro-groups occupy both ortho-positions, as in 3:5-dinitro-4-aminobenzoic acid, the amino-group is not diazotised to hydrogen, but to hydroxyl, and the carboxyl group in the para-position is left unchanged. In order to study the formation of these by-products, the action of nitric acid on the original amines was investigated and the results showed that in each case in which nitration during diazotisation yields a by-product, the acid yielded a nitrated nitroamine. From 3:5-dibromo-4-aminobenzaldehyde two nitroamines were obtained, one of which contains the aldehydic group unchanged, whilst in the other this is replaced by the nitro-group; the author considers that the latter substance is obtained by secondary nitration. In the case of 3:5-dibromoanthranilic acid, an intramolecular rearrangement of bromine and the nitro-group of the ring takes place subsequently to nitration. With the exception of 3:5-dinitro-4-aminobenzoic acid, a small quantity of a diazonium compound was obtained in each experiment, probably due to the formation of nitrous acid from the nitric acid. The results of direct nitration of the amines suggest that the accessory reaction in diazotisation takes place in such a way that a portion of the original substance is first transformed into nitroamine, which is then diazotised and reduced, thus forming the by-product. The diazotisation of a nitroamine being essentially a reduction, an attempt to bring about this transformation by means of alcohol was made and treatment of 2:6-dibromo-4-nitrophenylnitroamine with alcohol resulted in the formation of 3:5-dibromonitrobenzene. The same change was also effected by Witt's method of diazotisation, which is also accompanied by denitration. The following substances do not

appear to have been described previously: 3:5-dichloro-4-amino-benzoic acid, prepared by chlorination of *p*-aminobenzoic acid, m. p. 291°; 3:5-dinitro-4-nitroaminobenzoic acid, yellow plates containing 1H<sub>2</sub>O, softens at 80°, decomp. 135—136°; 3:5-dinitro-bromobenzene, obtained by diazotising 2:4-dinitro-6-bromoaniline, long, pale yellow plates, m. p. 77°.

H. J. E.

**The Azo-ester Reaction of 3-Aminopyridine.** OTTO DIELS and GEORG BEHNEN (*Ber.*, 1923, 56, [B], 561—566).—It has been shown previously that strongly basic amines react with azodicarboxylic esters to give amides, whereas aliphatic amines generally yield stable additive products of differing types. 3-Aminopyridine is found to behave in the same manner as the strong bases, but in addition to diamides it also yields the ester amides of which representatives have not previously been obtained; they are remarkable for the extraordinary readiness with which the alkyl group of the carbalkoxy-residue suffers replacement.

Ethyl azodicarboxylate reacts vigorously with 3-aminopyridine in alcoholic solution, with the formation of azodicarboxy-di-3-pyridylamide, N<sub>2</sub>(CO·NH·C<sub>5</sub>H<sub>4</sub>N)<sub>2</sub>, pale yellow needles, m. p. 164° (decomp.). If the substances are allowed to react at -20°, ethyl azodicarboxy-3-pyridylamidate, C<sub>5</sub>H<sub>4</sub>N·NH·CO·N·N·CO<sub>2</sub>Et, orange-yellow, coarse needles, m. p. 136—137° (decomp.), is obtained; the substance decomposes slowly when preserved, rapidly when treated with dilute acids. The corresponding methyl ester, orange-yellow needles, m. p. 113° (decomp.), is prepared from 3-aminopyridine and methyl azodicarboxylate in methyl-alcoholic solution. It is converted by crystallisation from ethyl alcohol into the ethyl ester, m. p. 136—137°, which is also obtained from methyl azodicarboxylate and 3-aminopyridine in the presence of ethyl alcohol. The ethyl ester is converted by a solution of methylamine in alcohol at -20° into azodicarboxy-3-pyridylmethylamidate, C<sub>5</sub>H<sub>4</sub>N·NH·CO·N·N·CO·NHMe, red crystals, m. p. 137°, and by 5-naphthylamine in the presence of pyridine into the compound, (9)NH<sub>2</sub>C<sub>10</sub>H<sub>6</sub>(2)N(CO<sub>2</sub>Et)·NH·CO·NH·C<sub>5</sub>H<sub>4</sub>N, colourless, lustrous leaflets, m. p. 182° (decomp.) [the hydrochloride, perchlorate, and acetyl derivative, C<sub>21</sub>H<sub>21</sub>O<sub>4</sub>N<sub>5</sub>, m. p. 232° (decomp.), are described]. The compound is oxidised by hydrogen peroxide in the presence of glacial acetic acid to the substance

dark brown needles, decomp. above 250°.

H. W.

**Catalytic Hydrogenation of Alkyl-substituted Pyrroleazodyes.** HANS FISCHER and FRIEDRICH ROTHWEILER (*Ber.*, 1923, 56, [B], 512—519).—Aminopyrroles have previously been very difficultly accessible substances. A number of them are now obtained by the catalytic hydrogenation of pyrroleazo-dyes. Since, however, the behaviour of certain of the compounds is scarcely that which would be expected of substances containing the amino-group, the constitutions are assigned to them with

reserve, since the possibility that an extension of the ring has occurred is not excluded.

Reduction is effected in alkaline-alcoholic solution in the presence of platinum black. The formation of the hydrazo-compound takes place rapidly, after which further absorption of hydrogen proceeds much more slowly.

Reduction of 2 : 3 : 5-trimethylpyrrole-4-azobenzenesulphonic acid in alkaline solution leads to the production of 4-amino-2 : 3 : 5-trimethylpyrrole,  $\text{NH} \begin{array}{c} \text{CMe} \cdot \text{CMe} \\ \text{CMe} \cdot \text{C} \cdot \text{NH}_2 \end{array}$ , colourless crystals, m. p. 186°

(decomp.), and sodium sulphanilate, which are separated from one another by taking advantage of the ready solubility of the base and the insolubility of the salt in alcohol. The amine gives a hygroscopic *hydrochloride*, prismatic crystals, m. p. 234° (decomp.), and a crystalline *picrate*, m. p. (indefinite) 210–230° (decomp.), after becoming black at 180°. It could not be acetylated, benzoylated, methylated with methyl sulphate, or caused to react with phenylcarbimide.

5-Amino-3-acetyl-2 : 4-dimethylpyrrole,  $\text{NH} \begin{array}{c} \text{C}(\text{NH}_2) \cdot \text{CMe} \\ \text{CMe} = \text{C} \cdot \text{Ac} \end{array}$ , rods, m. p. 223° (decomp.) after darkening and softening at 220°, is obtained similarly from 3-acetyl-2 : 4-dimethylpyrrole-5-azobenzenesulphonic acid; it gives a *picrate*, m. p. 175–190°, after darkening at 175°, according to the manner of heating.

Ethyl 4-amino-2 : 5-dimethylpyrrole-3-carboxylate,

is obtained in the form of the *hydrochloride*, colourless, rectangular leaflets or slender needles, m. p. 212° (decomp.) after previous darkening and softening, by the reduction of 3-carbethoxy-2 : 5-dimethylpyrrole-4-azobenzenesulphonate. The corresponding *picrate* has, according to the mode of heating, m. p. 185–195° after softening at 150°. The *hydrochloride* (as also 4-amino-2 : 3 : 5-trimethylpyrrole) does not appear to lose the amino-group when treated with hydrogen iodide and glacial acetic acid.

3-Acetyl-2 : 4-dimethylpyrrole-5-azobenzenesulphonic acid is obtained in almost quantitative yield by coupling 3-acetyl-2 : 4-dimethylpyrrole-5-carboxylic acid with diazobenzenesulphonic acid, the carboxyl group of the pyrrole being eliminated. In a similar manner, diazotised *p*-nitraniline gives 3-acetyl-2 : 4-dimethylpyrrole-5-*p*-nitroazobenzene, an orange-coloured substance, m. p. 198° (decomp.). 3-Carbethoxy-2 : 4-dimethylpyrrole-5-azobenzene, small, yellow needles, m. p. 127°, is obtained from its components in acetic acid solution; it gives a well-crystallised *picrate*, m. p. 156–158° (decomp.), and *styphnate*, m. p. 163° (decomp.). 2 : 4-Dimethylpyrrole-3-carboxylic acid couples with loss of carbon dioxide with diazobenzenesulphonic acid, *p*-nitrobenzenediazonium chloride, and *p*-dichlorobenzenediazonium chloride, to give crystalline dyes. A loss of the carbethoxy-residue from ethyl 2 : 4-dimethylpyrrole-3 : 5-dicarboxylate does not occur even under the energetic action

of diazotised picramide. The aldehyde residue of substituted pyrroles cannot be displaced by the azo-residue; the compounds investigated were ethyl 5-aldehydo-2:4-dimethylpyrrole-3-carboxylate, 3-acetyl-2:4-dimethylpyrrole-5-aldehyde, 2:3:5-trimethylpyrrole-4-aldehyde, ethyl 4-aldehydo-1-*p*-tolyl-2:5-dimethylpyrrole-3-carboxylate, and ethyl 4-hydroxy-5-aldehydo-2-methylpyrrole-3-carboxylate.

H. W.

**Oxidative Fission of Hydrazones and Derivatives of Oxyhydrazine.** MAX BERGMANN, REINHOLD ULPTS, and CHARLOTTE WITTE (*Ber.*, 1923, 56, [B], 679—682).—The isolation of reducing compounds of the sugar group from complex mixtures is frequently effected in the form of their hydrazones from which their regeneration is frequently a matter of difficulty. The possibility of oxidative fission by means of perbenzoic acid has been examined in the cases of simple anils and hydrazones.

Benzophenone is obtained in about 55% yield by the action of perbenzoic acid on an ethereal solution of benzophenonephenylhydrazone. Under similar conditions, benzylideneaniline yields much benzaldehyde and considerable quantities of nitrosobenzene. Oxidation of benzaldehydephenylhydrazone gives benzaldehyde-

phenylhydrazone oxide,  $\text{O} \begin{array}{c} \text{CHPh} \\ \diagup \quad \diagdown \\ \text{N} \cdot \text{NHPh} \end{array}$ , pale yellow needles or

prisms, m. p. 201° (corr. decomp.), which is a stable substance. It is decomposed by boiling glacial acetic acid with production of benzaldehyde and phenyl acetate, but the fission is by no means smooth, and large quantities of other substances are produced; a portion is isomerised to benzoylphenylhydrazine, thus showing that the carbon-nitrogen skeleton of the original material is preserved intact in the oxidation product. The oxide is decomposed by phenylhydrazine into dibenzoylphenylhydrazine,  $\text{NHBz} \cdot \text{NBzPh}$ , m. p. 176°, and much benzonitrile, by aniline into *p*-aminodiphenyl, m. p. 54°, and by dimethylaniline into benzamide.

Furfuraldehydephenylhydrazone is oxidised by perbenzoic acid in ethereal solution to furfuraldehydephenylhydrazone oxide,  $\begin{array}{c} \text{CH} \cdot \text{CH} \\ | \quad \diagup \quad \diagdown \\ \text{CH} \cdot \text{O} \end{array} \text{C} \cdot \text{CH} \begin{array}{c} \text{N} \cdot \text{NHPh} \\ | \\ \text{O} \end{array}$ , pale yellow or yellowish-brown crystals which appears to be considerably less stable than the corresponding derivative of benzaldehyde.

H. W.

**Colloid Chemical Characteristics of Albumin Fractions. Sensitisation and Protective Action of Hydrophilic Colloids.** J. REITSCHÖTTER (*Kolloid Z.*, 1923, 32, 47).—In opposition to the view held by Pauli, the author has shown that solutions of albumin cannot be submitted to prolonged dialysis without permanent changes taking place in the material. The changes can be detected by the effect of electrolytes on the solutions. Thus an albumin-ferrie hydroxide sol, which has been submitted to electro-dialysis through parchment membranes, is distinctly more sensitive to electrolytes than the pure ferrie hydroxide sol. Albumin-ferrie hydroxide sols are more sensitive to electrolytes than paraglobulin-

ferrous hydroxide sols. The paraglobulin from diphtheria and tetanus serum has a much greater negative charge than the paraglobulin from normal and anti-infection sera. Specific anti-substances have a definite charge which is always more negative than that of paraglobulin from normal sera. J. F. S.

**Some Methods for the Preparation of Ultra-visible Albumin Sols and the Significance of these for Colloid Chemistry and Biology.** A. FODOR (*Kolloid Z.*, 1923, 32, 103—107).—The author describes methods for the preparation of ultra-visible sols of albumin, globulin, and casein. By means of these sols it is shown to be possible to follow the change from the sol to the gel condition. The process consists, in the case of albumin, in the dehydration of the strongly solvated enhydrones of this protein, which are ultramicroscopically invisible, to such an extent that the particles become visible in a dark field illumination. This is achieved by diluting white of egg with ten times its volume of water, adding a crystal of thymol, and keeping for several months in an ice-chest. The solution thereby becomes very opaque, but there is only the smallest amount of coagulation. This is filtered and the filtrate placed in the field of an ultramicroscope which is illuminated by a paraboloid condenser, when relatively large aggregations which do not move markedly are visible. If the solution is now made faintly alkaline with sodium hydroxide, the aggregates are resolved into the primary particles which are in violent motion. If the solution is heated, the field becomes optically empty, but if the solution is kept for a week at 0°, the visible enhydrones are again apparent. J. F. S.

**Nature of the Coagulation of Proteins by Alcohol and other Organic Substances.** W. W. LEFESCHKIN (*Kolloid Z.*, 1923, 32, 100—103).—The nature of the coagulation of albumin by alcohol has been investigated. It is shown that the coagulation by alcohol is similar to the coagulation by heat, and that all factors which affect the heat coagulation have exactly the same effect on coagulation of proteins by alcohol. The addition of alcohol to albumin solutions brings about an acceleration of the velocity of the denaturation, the amount of the acceleration being proportional to the amount of alcohol added. Such a denaturated product would be insoluble in water, as is found to be the case with the albumin coagulum after it has remained in contact with alcohol for a short time. J. F. S.

**Conditions of Reversible and Irreversible Coagulation of Proteins by Salts.** W. W. LEFESCHKIN (*Kolloid Z.*, 1923, 32, 44—46).—Solutions of albumin are coagulated reversibly by salts of the alkali metals, but irreversibly by salts of the alkaline-earth and heavy metals. Further, the coagulation by salts of the alkali metals is irreversible if it takes place in the presence of hydrochloric acid. The varying behaviour is due to the velocity with which the albumin in the various cases is denaturated. The presence of alkaline-earth and heavy metal salts and hydrochloric acid

accelerates the denaturisation in various ways, which are explained in the paper, and so render the coagulation irreversible. J. F. S.

**Relationship of Neutral Salts to Acid Albumins.** SUSUMU MATSUMURA and JOHANN MATULA (*Kolloid Z.*, 1923, 32, 37—42).—After a discussion of the views held by Pauli (A., 1909, i, 618) and Hardy (A., 1906, i, 121) on the mechanism of the reaction between neutral salts and solutions of acid proteins, the authors, who disagree with the views hitherto put forward, describe a number of parallel experiments on the action of hydrochloric acid and sodium chloride on solutions of the chloride of the protein obtained from horse-serum. The serum used had been preserved for several years under toluene and had deposited the whole of the globulin. The dialysed serum was mixed with equal volumes of 0.005N-, 0.01N-, and 0.05N-solutions of hydrochloric acid, respectively, and three solutions thus obtained in which the protein was not completely saturated, saturated, and over-saturated, with acid. These three solutions were treated with equivalent quantities of hydrochloric acid and sodium chloride at the ordinary temperature and at 100°. At the ordinary temperature, the coagulation of the protein takes place with much smaller concentrations of the salt than of the acid, whilst at 100° the same result is observed, but, further, in the case of hydrochloric acid, the amount of precipitation in hot solution is exactly the same as in cold solution, whereas with sodium chloride the amount of precipitate is greater in hot solutions than in cold. A further series of experiments on the electrical conductivity of protein chloride solutions to which hydrochloric acid and sodium chloride, respectively, have been added shows that the salt solution increases the specific conductivity from three to five times as much as the hydrochloric acid. The results indicate that the views put forward previously are inaccurate, and that the action of neutral salts consists in the first place in the formation of a poorly hydrated complex of the protein chloride and the

neutral salt, of the type  $\text{NaCl} \cdot \text{R} \cdot \begin{smallmatrix} \text{NH}_2\text{HCl} \\ \text{CO}_2\text{H} \end{smallmatrix}$ , whereby the electrolytic dissociation of the protein chloride is not markedly affected, but the viscosity is much reduced, and in the second place in the displacement of the ionisation of this complex which brings about the coagulation. J. F. S.

**Precipitation of Serum-albumin by Copper Salts.** SUSUMU MATSUMURA and JOHANN MATULA (*Kolloid Z.*, 1923, 32, 115—118).—The authors have investigated the conditions under which solutions of cupric chloride cause the precipitation of serum-albumin solutions. It is shown that serum and albumin solutions which are entirely free from electrolytes are not precipitated by cupric chloride. Precipitation may be brought about by the presence of large quantities of neutral salts or by the presence of small quantities of alkalis. The nature of the precipitation in the two cases is different. In the first case, the amount of the precipitate increases with the amount of copper chloride added, whilst

in the second case the precipitation is restricted to a definite range of quantities of copper chloride, and with amounts beyond this it passes back into solution. The precipitate in the second case can also be brought back into solution by the addition of neutral salts, whilst in the first case the precipitate is insoluble both in excess of cupric chloride and neutral salt. Copper chloride solutions form positively charged complexes with dialysed albumin, in which the copper chloride is not united to the albumin molecule in the same place as the acid in acid albumins.

J. F. S.

**Reaction of Proteins with the Acids of Soaps and Fats.** I. SUSUMU MATSUMURA (*Kolloid Z.*, 1923, 32, 173—176).—The behaviour of solutions of sodium oleate with dialysed horse-serum has been investigated. It is shown that the whole of the proteins in sera, and also in egg-albumin, give precipitates when treated with soaps of the higher fatty acids. The precipitation is incomplete, but may be made complete by the removal of the free alkali, which retards the formation of the precipitate. The precipitates from dialysed sera which are soluble in sodium chloride solution may be brought permanently into solution by warming at 56°. On the other hand, sera which have been previously warmed at 56° are no longer precipitated by soap solutions. The soap precipitates, which are insoluble in sodium chloride, namely, those of serum-globulin and ovoglobulin, dissolve on warming, but on again cooling they are reprecipitated.

J. F. S.

**The Plant Albumin "Leucosin."** HEINRICH LÜERS and MAX LANDAUER (*Biochem. Z.*, 1922, 133, 598—602).—Leucosin, obtained from barley, and purified by the method of Osborne, shows the following distribution of its nitrogen: ammonia-N, 9.4%; melanin-N, 1.1%; hexone-base-N, 26%; monoamino-N, 63.1%. The results obtained using a shortened method of hydrolysis are also given and show agreement with those given by the longer process.

W. O. K.

**Physical Chemistry of the Globulins. I. Alkali and Alkaline-earth Globulins.** I. Alkali and Alkaline-earth Globulins. MONA ADOLF (*Koll. Chem. Beihefte*, 1923, 17, 1—50).—A physico-chemical investigation of the portion of globulin which is insoluble in water. By electro-dialysis it is found possible to precipitate from human sera and exudations a globulin which is insoluble in water. This material did not change the electrical conductivity of pure water and contained 0.215% of ash and 0.047% of phosphorus. By means of solubility determinations of globulin in alkali and alkaline-earth hydroxide solutions, it is shown that these substances combine with globulin in equivalent quantities, and not in molecular quantities, as hitherto supposed, to form neutral salts. Globulin yields only one form of neutral salt with alkali, a property in which it differs from casein; this salt is not hydrolysed markedly. The power of globulin to combine with bases in an excess of strong alkali hydroxide solution is represented by  $15 \times 10^{-3}$  g. equivalent per g. of albumin, and is proportional to the amount of the latter

substance. The degree of hydrolysis of the albumin salt in aqueous solution is 24%, and the mean acid dissociation constant  $1 \times 10^{-10}$ . Weak bases apparently combine with less globulin, but if referred to isohydric concentrations with more globulin. The salts so formed are all more strongly hydrolysed. The same is true for all proteins hitherto investigated. The viscosity curve for a solution of constant albumin content but increasing alkali hydroxide concentration passes through a maximum both for strong and weak bases. The hydroxide concentration of the viscosity maximum and that at which the maximum combination takes place do not coincide, but the latter quantity corresponds with the maximum electrical conductivity of the protein salt. By measurements of the concentration of hydroxyl-ions and the viscosity, it is shown that the combination of globulin with the base is a time process, and is practically complete after twenty-four hours. The value of  $\lambda_{\infty}$  for the neutral alkali globulinate has been deduced from electrical conductivity measurements, and the following values have been obtained for 25°: sodium globulinate,  $\lambda_{\infty} = 100 \text{ ohms}^{-1}$ ; potassium and ammonium globulinate, 123—124  $\text{ohms}^{-1}$ . From these values the mobility of the globulinate-ion is found to be 50. The valency of the negative globulin is found by the Walden-Ostwald rule to be 4. Three g. of globulin are neutralised by 1 millimol. of alkali hydroxide, and from this the equivalent weight of globulin is calculated to 3000, which indicates a molecular weight of 12,000.

J. F. S.

**Antagonistic Behaviour of Albumin toward Globulin.** G. A. BROSSA (*Kolloid Z.*, 1923, 32, 107—115).—Suspensions of globulin are peptised by negative colloidal solutions of dyes such as Congo-red and benzo-purpurin, and also by positive solutions of colloidal dyes such as night-blue. Of these sols, that obtained by peptising a suspension of globulin with Congo-red has been investigated. The Congo-red-globulin sol is extremely sensitive to electrolytes, and is coagulated by much smaller concentrations of electrolytes than the pure dye sol. The sensitiveness increases with increasing globulin content. The night-blue-globulin sol is also very sensitive. Albumin has a protecting action on the Congo-red-globulin sol, just as it has on the pure Congo-red sol. The antagonistic action of albumin and globulin is also manifested if the albumin or globulin in a serum is increased. A mixture of a Congo-red sol and a serum rich in globulin is much more sensitive than a mixture of a Congo-red sol and a serum rich in albumin. From this it is deduced that generally a serum which is richer in globulin than in albumin is more sensitive to electrolytes than one which is richer in albumin than in globulin for the same total protein content. This rule is found to be true when the globulin rich horse-serum is compared with the globulin poor rabbit-serum, and when pathological human-serum is compared with normal human-serum. From Kruyt's experiments (*ibid.*, 1922, 31, 338), it follows that colloidal solutions of negative dyes such as alkali-blue, water-blue, Chicago-blue, as well as the positive dye night-

blue, are rendered more sensitive by the addition of tannin. Since in this case the increase in sensitiveness cannot be occasioned by the discharge of the colloid particles by the added substance, it is very questionable whether the discharge of the colloid particles causes the increase of sensitiveness in the present case. J. F. S.

**The Hydrolysis of Edestin with Sulphuric Acid.** J. S. JÄTTISCHNIKOV (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 105–108).—Edestin is hydrolysed with sulphuric acid of various concentrations, varying the temperatures and the times of reaction. The reaction mixture is in each case neutralised with sodium hydroxide, and Fassbender's reagent added. The precipitate is analysed for nitrogen by Kjeldahl's method, and the amount of nitrogen found serves as a measure of the amount of unhydrolysed albumin. Increase in temperature and in  $H^+$ -concentration have an accelerating effect on the hydrolysis, the influence of the former being more marked. R. T.

**Identity of Hordein and Bynin.** HEINRICH LÜERS (*Biochem. Z.*, 1922, 133, 603–604; cf. A., 1919, i, 603).—The equation given in the previous paper for the calculation of the histidine-nitrogen is incorrect. The recalculated values are now given. W. O. K.

**The Products of Prolonged Tryptic Digestion of Casein.** SIGMUND FRÄNKEL and KATHARINE GALLIA (*Biochem. Z.*, 1922, 134, 308–321).—Casein was digested with pancreatin for sixty days at  $37^\circ$ . A hot-water extract of the precipitate gave *d*-tyrosine anhydride and the mercuric sulphate precipitate of the filtrate contained tryptophan anhydride. On removal of mercury the filtrate was precipitated with phosphotungstic acid, and the filtrate from this on removal of foreign ions gave successive crops of crystals. The first crop was identified as *d*-tyrosine; it had a higher rotation,  $[\alpha]_D + 17.9$ , than any previously recorded value. The second and third crops consisted of *dl*-valin, and the fourth crop of *d*-valin. The formation of *d*-tyrosine is ascribed to a Walden inversion produced by an enzyme *Waldenase*. H. K.

**The Oxygen-dissociation Curve of Blood, and its Thermodynamical Basis.** W. E. L. BROWN and A. V. HILL (*Proc. Roy. Soc.*, 1923, [B], 94, 297–334).—On the assumption that the combination of oxygen or carbon monoxide with hæmoglobin in blood (as distinct from dialysed hæmoglobin) is a reversible chemical reaction of the following type:  $H(Hb)_n + nO_2 \rightleftharpoons H(HbO_2)_n$  (cf. A., 1910, i, 288; A., 1922, i, 193), the authors have calculated, with the aid of the van't Hoff isochore, that the heat of reaction,  $q$ , of 1 mol. of hæmoglobin,  $H(Hb)_n$ , with  $n$  mols. of oxygen at constant volume is 19,000 cal. in the presence of carbon dioxide and 30,500 cal. in its absence. Direct estimations of the heat  $Q$  evolved when 1 mol. of oxygen combines, at constant volume, with hæmoglobin in blood have given a value of 14,400 cal. in the absence of carbon dioxide. The ratio  $q/Q$  is obviously equal to  $n$ ; hence  $n = 305/144 = 2.1$  approximately. This agrees with the value

obtained independently from the shape of the dissociation curve and from other data, and is consequently regarded as confirmation of the theory of the reversible chemical combination of oxygen with hæmoglobin. The difference in the value of  $q$  in the presence and absence of carbon dioxide is due to the absorption of heat which occurs when carbon dioxide is expelled from its combination with base by the stronger acid,  $H(HbO_2)_n$ . Calculations of the acid dissociation constants of unsaturated hæmoglobin and carboxy-hæmoglobin [ $\overline{HHb}_n$  and  $H(\overline{HbCO})_n$ ] have given values of  $7.5 \times 10^{-9}$  and  $5 \times 10^{-7}$ , respectively.

E. S.

**Tryptophan and Tyrosine Content of Hæmoglobin and other Blood Proteins.** U. KIYOTAKI (*Biochem. Z.*, 1922, 134, 322—335).—Globin prepared in a variety of ways contains 3.6% of tryptophan when estimated colorimetrically by Fürth and Lieben's application of the Voisenet reaction. In agreement with this, the amount of melanoidin formed by acid hydrolysis was 3.3%. The tryptophan is only liberated with difficulty from hæmoglobin, 18% being set free after three weeks' tryptic digestion with a highly active trypsin. The tyrosine content of globin was found to be between 3.5% and 4%, corresponding with one molecule of tyrosine for every molecule of tryptophan. In serum-albumin 5 mols. of tyrosine and in serum-globulin 2 mols. of tyrosine were found for every tryptophan molecule.

H. K.

**Hydrolysis of Yeast-nucleic Acid with Dilute Alkali at Room Temperature (Conditions of Steudel and Peiser).** P. A. LEVENE (*J. Biol. Chem.*, 1923, 55, 9—13).—Contrary to the results obtained by Steudel and Peiser (*A.*, 1922, i, 782), it has been found that, under the conditions used by these authors, the removal of guanylic acid from yeast-nucleic acid is incomplete. Moreover, the formation of the remaining three nucleotides occurs simultaneously with that of guanylic acid.

E. S.

**Determination of the Isoelectric Point of Gelatin. A Criticism of Patten and Kellems's Method.** THOMAS SLATER PRICE (*T.*, 1923, 123, 410—412).

**Keratinisation.** UBALDO SAMMARTINO (*Biochem. Z.*, 1922, 133, 476—486).—Analyses have been carried out of the amino-acids of keratin from hair, nails, and from corns (of the foot). The cystine content, particularly, varies according to the source of the keratin.

W. O. K.

**The Origin of the Humin Formed by the Acid Hydrolysis of Proteins. VII. Hydrolysis in the Presence of Ketones.** ROSS AIKEN GORTNER and EARL R. NORRIS (*J. Amer. Chem. Soc.*, 1923, 45, 550—553; cf. *A.*, 1915, i, 726; 1916, i, 681; 1918, i, 84; 1920, i, 400, 450).—Fibrin was hydrolysed alone and in the presence of acetone and acetophenone, and the distribution of the nitrogen among the products was studied. Apparently the presence of ketones does not alter the nitrogen distribution as measured by

Van Slyke's method. Acid-insoluble humin formed during a protein hydrolysis does not apparently come from the interaction of a ketone and tryptophan. W. G.

**The Specificity of Enzymes.** RICHARD WILLSTÄTTER and RICHARD KUHN. I. The Theory of Time Value Quotients. (*Z. physiol. Chem.*, 1923, 125, 1—27).—A general discussion is given of the kinetics of enzyme action with special reference to the possible modes of action of accelerators and inhibitors. The question of the identity of enzymes in different preparations is considered, and the related question of the specificity of enzymes. A distinction is drawn between relative and absolute specificity, the first being a quantitative and the second a qualitative difference in their modes of attack on substrates. W. O. K.

**Units of Enzymes.** RICHARD WILLSTÄTTER and RICHARD KUHN (*Ber.*, 1923, 56, [B], 509—512).—A system of nomenclature is proposed in which the figures are directly proportional to the quantities and enzymatic concentrations of the preparations. The lipase unit is the quantity of enzyme which causes the fission of 2.5 g. of olive oil to the extent of 24% during one hour. The amylase unit is one hundred times the quantity of enzyme of  $k=0.01$  and the peroxydase unit is equal to 1 g. of the purpurogallin number I. The lipase and amylase values are the number of units in 1 cg. The saccharase unit (*SE*) is the amount of enzyme in 50 mg. of material containing invertin of the time value 1 in accordance with the definition of O'Sullivan and Thompson. The purity of an invertin preparation (*SW*) is expressed by the reciprocal of the time-value, and thus denotes the number of saccharase units in 50 mg. substance. The relationship of the saccharase value to the inverting power as defined by von Euler and Svanberg is expressed by the equation:  $SW = If/46.176$ . The expressions for quantity and concentration are not universally applicable for invertin and other enzymes, since their behaviour towards sucrose is considerably influenced by the varying amounts of foreign matter with which they are associated. For the strict comparison of saccharase preparations of different origin the dissociation constants should be appended to the *SW* and *SE*. Invertins of different affinities are compared by calculation of the units measured in the usual manner, which is sufficiently exact for preparative work to an invertin of the medium affinity constant=50 ( $k=0.020$ ). The "reduced saccharase unit" is calculated according to the formula  $SE_{red} = S.E.(n+k/n+0.02)$ , in which  $n$  is the normality of the sucrose solution in which the constants of the reaction are estimated. H. W.

**The Nomenclature of Autolytic Enzymes.** K. G. DERNEY (*Biochem. Z.*, 1922, 133, 432—433).—The author proposes to classify the proteolytic enzymes of plant or animal cells as primary proteases (pepsinases), secondary proteases (trypsinases), and tertiary proteases (ereptases), which act on protein in acid solution, on denatured protein and peptone in alkaline and neutral solution, and on peptides in alkaline solution, respectively. W. O. K.

**A Comparison between the Chemical and Physiological Characteristics of Pepsin and Rennin.** FREDERIC FENGER (*J. Amer. Chem. Soc.*, 1923, 45, 249—255).—Pepsin and rennin are proteins possessing widely different properties. Pepsin is coagulated by heat and is colloidal in nature, but rennin is a decomposition product of protein of the acid-albumin type, and is not precipitated on boiling. Pepsin may be dialysed without loss, but rennin readily diffuses through a parchment membrane. Proteolytic or peptic activity does not seem to be a part of the true physiological characteristics of the milk-curdling enzyme. Both enzymes are present in the stomach of the suckling calf, but in that of the adult hog only pepsin was found. W. G.

**The Influence of Starch on Peptic Digestion.** ANTON FISCHER (*Biochem. Z.*, 1922, 134, 360—362).—Contrary to statements in physiological literature, the addition of starch has no inhibiting action on the digestive action of pepsin. H. K.

**The Specificity of Enzymes. II. Saccharase and Raffinase Activity of Invertase.** RICHARD WILLSTÄTER and RICHARD KUHN (*Z. physiol. Chem.*, 1923, 125, 28—92).—The influence of hydrogen-ion concentration on the hydrolysis of sucrose by invertase is apparently due to its action on the rate of decomposition of the compound of enzyme and substrate. This is shown by the fact that if the affinity constant  $K = \frac{[\text{Enzyme}][\text{Substrate}]}{[\text{Enzyme-Substrate}]}$  be determined from measurements of the kinetics of the inversion,  $K$  is independent of the hydrogen-ion concentration. The affinity constant  $K$  does not vary with the degree of purity of the enzyme preparation, but is different in preparations made from yeasts of different sources, varying in the preparations tested from 0.016 to 0.040. If to one preparation there is added the solution obtained by heating another preparation so as to inactivate it, filtering from any coagulated protein, the affinity constant of this first preparation may be altered, in all the combinations tried a value of  $K = 0.030$  being obtained.

Similar variations in the affinity constant of invertase for raffinose depending on the origin of the yeast have been found, and a comparison of the effects of invertase on raffinose and on sucrose leads to the conclusion that ratio of the affinity constants of the different preparations is constant, and likewise the ratio of the molar quantities of the two sugars hydrolysed by a given amount of invertase under optimum conditions, if extrapolated to the value for infinite quantities of substrate. There appear to be strong indications that the saccharase and raffinase present in invertase are identical. W. O. K.

**The Preparation of Highly Active Invertin and its Sulphur Content.** H. VON EULER and K. JOSEPHSON (*Ber.*, 1923, 56, [B], 453—455).—The term invertin is applied to the natural group of enzymes obtained from yeast-cells or similar materials which causes the enzymatic inversion of sucrose and contains saccharase

as its main component. Highly active specimens ( $I_f=182$ ) are readily obtained from "aged" autolysed yeast-juice by fractional precipitation and dialysis combined with adsorption by aluminium hydroxide and elution with potassium arsenate solution.

A specimen which has the value  $I_f=182$  contains 0.38% of sulphur, corresponding with 0.48% S in a specimen having  $I_f=230$ . If this sulphur content is due to the presence of one atom of sulphur in the saccharase molecule, the combining weight of the latter is 6700, a value which is somewhat greater, but of the same order of magnitude as that derived from the analysis of silver saccharase.

H. W.

**Saccharase.** H. VON EULER and K. JOSEPHSON (*Ber.*, 1923, 56, [B], 446—452).—The preparation of highly active saccharase from autolysed yeast-juice is effected by a combination of the methods of fractional precipitation and dialysis with those of adsorption by aluminium hydroxide and elution with potassium arsenate. The parallelism between phosphorus content and activity ceases when the value of  $I_f$  exceeds about 100. The phosphorus content of the most active specimens ( $I_f=210$  at 18°) is 0.15%, and is therefore considerably higher than the lowest value recorded by Willstätter (0.03—0.006%), whose specimens were obtained from "aged" autolysed juice with the aid of lead acetate (cf. Willstätter and Racke, A., 1922, i, 598; Willstätter, Graser, and Kuhn, A., 1922, i, 1200; Willstätter and Wassermann, this vol., i, 69). Analysis of the most highly active specimens gives ash=4.0%, C=45.58%, H=6.70%, N=12.7%, P=0.15%, As<0.1%.

The preparation of the silver compound of saccharase (von Euler and Josephson, A., 1922, i, 1076) has been repeated with highly active saccharase; it contains about 2% of silver, thus indicating a minimum molecular weight of about 5400 for the enzyme.

The methods of indicating the activity of saccharase preparations are described. The conversion of the inverting capacity ( $I_f$ ) to the time values of O'Sullivan and Thompson (T., 1899, 57, 834) is effected by multiplication by the factor 58.6. H. W.

**The Action of Quinine and Quinine Derivatives on Stomach Lipase.** P. RONA and M. TAKATA (*Biochem. Z.*, 1922, 134, 118—130).—Stomach lipase (from the small stomach of a dog by Pavlov's method) is inhibited by quinine and its derivatives, quinidine, optoquin, eucupin, and vuzin, to an extent corresponding with their property of lowering the surface tension as measured by the drop number. The degree of inhibition depends on the hydrogen-ion concentration of the solution and therefore on the degree of dissociation of the quinine salt, and on the quinine concentration, but not on the concentration of the ferment. The quinine concentration-inhibition curve is an adsorption isotherm, the logarithm of the quinine concentration being proportional to the logarithm of the inhibition. H. K.

**The Action of Quinine and of Atoxyl on Pancreatic Lipase.** P. RONA and R. PAVLOVIĆ (*Biochem. Z.*, 1922, 134, 108—117).—The action of pancreatic lipase is strongly inhibited by quinine, but not by atoxyl. Liver lipase, however, is very sensitive to atoxyl. If the logarithms of the quinine concentration be plotted against the logarithms of the degree of inhibition, a straight line is obtained. Sodium fluoride inhibits the action of pancreatic lipase slightly, that of liver and serum lipase strongly. H. K.

**Pancreatic Enzymes. I. Determination of Pancreatic Fat Hydrolysis.** RICHARD WILLSTÄTTER, ERNST WALDSCHMIDT-LEITZ, and FRIEDRICH MEMMEN (*Z. physiol. Chem.*, 1923, 125, 13—131).—The activity of the lipase of the pancreas, unlike that of invertase, is dependent on its state of dispersion and on the colloidal material present in the solution containing it. In the case of invertase, these factors do not affect the activity, but only the stability of the preparations (cf. A., 1922, i, 1200). The activity of lipase is, of course, also dependent on the hydrogen-ion concentration, and so, as in the hydrolysis of triolein, acid is being constantly produced and the rate of the reaction thus being changed, direct measurement of the activity is not possible. The estimation of the activity may be carried out in three ways, (1) in an acid medium, of constant  $P_H$  of 4.7, this being approximately the  $P_H$  on adding oleic acid to water; (2) in an alkaline medium, the reaction being kept constant by the presence of a large amount of buffer solution, which, however, interferes to some extent with the activity; (3) in a medium alkaline at first, which, however, is allowed to become acid as the reaction proceeds. In the last case, the results are calculated from the observed course of the hydrolysis. As the activity of the enzyme solution depends on the other substances present, it is necessary, in order to obtain comparable results, to add activators, a suitable combination being calcium chloride and albumin.

If the activity of lipase adsorbed by various adsorbing surfaces be measured, it is found that the adsorbents fall into two groups, those which at most only slightly diminish the activity of the lipase (e.g., kaolin or aluminium hydroxide), and those which render the adsorbed lipase practically inactive (tristearin and cholesterol). It is suggested that, in the latter cases, the specifically active groups of the lipase molecule are held firmly by the surface, whilst in the former cases the active groups are free, and adsorption depends on other groups of the molecule. W. O. K.

**Pancreatic Enzymes. II. Pancreatic Lipase.** RICHARD WILLSTÄTTER and ERNST WALDSCHMIDT-LEITZ (*Z. physiol. Chem.*, 1923, 125, 132—198).—Pancreatic lipase, as obtained by extraction of the pancreatic glands by glycerol, is mixed with amylase and trypsin. Lipase shows both acid and basic properties, and is adsorbed by aluminium hydroxide and by kaolin. Pancreatic amylase and trypsin, on the other hand, have no marked acid properties, and when in a pure condition they are not adsorbed by aluminium hydroxide. However, when mixed with lipase they

are adsorbed to some extent, but at most a very small amount of these is washed out by ammonium phosphate, which removes the lipase. On repeating the process, lipase is obtained free from amylase and trypsin. Amylase and trypsin may be separated by utilizing the fact that the basic properties of trypsin are more marked, and that it is preferentially adsorbed from acid solution by kaolin.

Further purification of the lipase is effected by adsorbing on kaolin, and extracting with alkali phosphate. This may be followed by adsorption on cholesterol or tristearin, which are particularly selective in their adsorptive action. Very full details of these processes are given in the original paper. Only traces of the colour reactions of any known group of organic compounds are given by the purified lipase, which has been obtained in a concentration three hundred times that in dried pancreas.

W. O. K.

**Ferments and Light. I. Diastase. I. LUDWIG PINCUSSEN** (*Biochem. Z.*, 1923, **134**, 459—469).—Diastase, independently of dilution, loses its activity on exposure to ultra-violet rays in a quartz tube, but not in sunlight. The destruction by light is greatest at a  $P_H$  of 4.6, which is the optimum reaction for diastatic activity, and is least between  $P_H$  7 and 7.4. The presence of salt influences the rate of destruction by ultra-violet light, iodide increasing it. Sugars are without effect in ultra-violet light, although in presence of dextrose even sunlight is slightly effective. The effect of ultra-violet light is inhibited by glycine and starch. Temperature has apparently little effect.

W. O. K.

**The Action of Iodine on Diastase. L. BERCZELLER and J. FREUD** (*Biochem. Z.*, 1922, **133**, 493—501).—The action of saliva diastase is decreased by iodine, but it is not completely inactivated. Starch protects the diastase against the action of iodine. In the same way, the hydrolysis of starch by mineral acids is also inhibited by iodine.

W. O. K.

**The Action of Calcium on the Clotting of Milk by Rennin. P. RONA and E. GABBE** (*Biochem. Z.*, 1922, **134**, 39—75).—An extensive series of experiments was carried out on the influence of calcium on the clotting of milk under specified conditions as regards dilution, time, temperature, and hydrogen-ion concentration. The course of fermentation was followed by observing the temperature at which samples removed at intervals were clotted by heat. If calcium chloride is added at the beginning of the fermentation, the time which elapses before clotting is the longer the higher the calcium content. Small concentrations of calcium stimulate the ferment action, but large concentrations inhibit it. If, however, the calcium chloride is added after the fermentation has been in progress some time, the period before clotting is prolonged. The conversion of caseinogen into casein is only complete at hydrogen-ion concentrations between  $P_H$  6.0 and 6.4.

H. K.

**Experiments on Liver Catalase.** PETER RONA and ARISTIDA DAMBOVICBANU (*Biochem. Z.*, 1922, 134, 20—38).—A series of experiments carried out on the catalase of calf's liver showed that the activity is not affected by the particular buffer mixture used, and that the optimum activity is exhibited over a broad range of  $P_H$  round about 7 and is only inhibited at  $P_H$  11. If the ferment is in excess of the hydrogen peroxide, the reaction is unimolecular, but if the ferment is only sufficient to decompose 65 to 80% of the hydrogen peroxide, the reaction is bimolecular. Chloridion inhibits the fermentation, but a 0.0005 molar sodium hydrogen carbonate solution is sufficient to inhibit the action of a 0.154 molar sodium chloride solution. If, however, the ferment is in large excess over the peroxide, the inhibiting action of chloridion is not so noticeable.

H. K.

**Ferments and Light. II. Urease.** I. LUDWIG PINCUSSEN and NAOSABURO KATO (*Biochem. Z.*, 1923, 134, 470—475).—Urease gradually loses its activity on exposure to sunlight or to ultra-violet light, most rapidly apparently at the reaction optimum for the activity of the urease.

W. O. K.

**Synthesis of Carbamide with the Enzyme Urease.** EDWARD MACK and DONALD S. VILLARS (*J. Amer. Chem. Soc.*, 1923, 45, 501—505).—It is shown that, when concentrated solutions of ammonium carbonate and carbamate are used, the enzyme urease acts reversibly and increases the velocity of formation of carbamide, hastening the attainment of the equilibrium. A 1% solution of the enzyme will bring about equilibrium in a 10*N*-ammonium carbonate-carbamate solution, containing about equal amounts of each salt, in about ten hours at 55°, whereas with a 0.1% solution of the enzyme the reaction is only about one-third complete in ninety-eight hours and without any enzyme equilibrium would be attained only after about six hundred days at 55°.

W. G.

**The Action of Urease in the Decomposition of Carbamide.** EDWARD MACK and DONALD S. VILLARS (*J. Amer. Chem. Soc.*, 1923, 45, 505—510).—Experimental evidence is given to show that the transformation of ammonium cyanate into carbamide is not catalysed by the enzyme urease, but rather that the enzyme is slowly poisoned by the cyanate. When carbamide is hydrolysed, in the presence of urease, forming ammonium carbamate, which changes into the carbonate, there is simultaneous formation of ammonium cyanate from the carbamide. When considering the different stages possible in the transformation of carbamide into ammonium carbonate, it is shown by a process of elimination that the particular stage catalysed by the urease is the transformation of carbamide into ammonium carbamate.

W. G.

**The Urease of Fungi.** A. GORIS and P. COSTY (*Compt. rend.*, 1923, 176, 412—414).—A study of the urease of the higher fungi and in particular of *Boletus edulis*, Bull. This urease is not very sensitive to heat, only being destroyed at 76°. The optimum temperature is 30—38°. It is very sensitive to mineral and organic

acids. Of the organic acids studied, tartaric acid is the most injurious and acetic acid the least. The enzyme is less sensitive to alkalis, and it is able to resist a concentration of ammonium carbonate ten times as great as that of sodium carbonate, which destroys it. Of the neutral salts studied, those of calcium exert the greatest retarding action, and then, in descending order, those of sodium, potassium, ammonium, and magnesium. In general, antiseptics act very energetically on this enzyme. W. G.

**Isomorphism in the Organo-metallic Series. V. Saturated Derivatives of Quinquevalent Metals and Metalloids.** P. PASCAL (*Bull. Soc. chim.*, 1923, [iv], 33, 170—180).—A study was made of the temperatures of fusion and solidification of binary mixtures of oxides and sulphides of triphenylphosphine, triphenylarsine, and triphenylstibine, and the temperatures of the commencement and completion of solidification of the mixed substances in varying proportions are given in tables and curves. The results may be conveniently summarised by designating the types of binary mixtures obtained, arranged in the order of decreasing crystalline analogy, by (1), (2), (3), (4), where (1) is the formation of mixed crystals in all proportions, the curve being spindle-shaped; (2) mixed crystals in all proportions, curve with a minimum; (3) no mixed crystals, curve with a transition point, and (4) no mixed crystals, curve showing a eutectic point, and the following indicates the type to which each binary mixture belongs:  $(\text{PPh}_3\text{O}, \text{AsPh}_3\text{O})=1$ ,  $(\text{PPh}_3\text{S}, \text{AsPh}_3\text{S})=2$ ,  $(\text{PPh}_3\text{O}, \text{AsPh}_3\text{S})=4$ ,  $(\text{PPh}_3\text{S}, \text{SbPh}_3\text{S})=2$ ,  $(\text{PPh}_3\text{O}, \text{SbPh}_3\text{S})=4$ ,  $(\text{AsPh}_3\text{O}, \text{AsPh}_3\text{S})=2$ ,  $(\text{PPh}_3\text{S}, \text{PPh}_3\text{O})=2$ ,  $(\text{PPh}_3\text{S}, \text{AsPh}_3\text{O})=4$ ,  $(\text{AsPh}_3\text{O}, \text{SbPh}_3\text{S})=4$ ,  $(\text{AsPh}_3\text{S}, \text{SbPh}_3\text{S})=2$ . It appears, therefore, that if in a pair of organo-metallic compounds the asymmetry of the central atoms is increased by the addition of oxygen in one and of sulphur in the other, the tendency to isodimorphism is increased. If, on the other hand, the central atoms are saturated by the same element—oxygen or sulphur—the tendency to isomorphism is increased. Binary mixtures in which the phenyl group of the phosphines was replaced by the  $-\text{OPh}$ ,  $-\text{SPh}$ , and  $\text{C}_2\text{H}_5-$  groups, were also examined. The same relations of isomorphism were found to exist between the phosphate and thiophosphate as between the phosphine oxide and sulphide, but isodimorphism occurs when aliphatic groups are introduced into one of the constituents of the binary mixture, or when phenyl and oxyphenyl derivatives are mixed. G. F. M.

**Substitution Factors of the Affinity Constants in the Group of the Arsinic Acids.** RICHARD LORENZ and ELISABETH BREHMER (*Ber.*, 1923, 56, [B], 742—750).—The dissociation constants of a large number of substituted phenylarsinic acids have been measured, and from the results the authors have constructed a table of factors for the mathematical expression of the influence of various groups in differing positions in the molecule. The following data are recorded, Wegscheider's factors for the carboxylic acids being placed within brackets: *o*-Nitro, 1.41, 1.51\* (103); *m*-nitro, 5.0, 5.5 (5.75); *p*-nitro, 5.3 (6.6); *o*-hydroxy,

0.42 (17.0); *m*-hydroxy, about 1.45\* (1.45); *p*-hydroxy, 0.55 (0.48); *o*-methyl, 2.4\* (2.00); *m*-methyl, 0.85\* (0.86). The factors marked with an asterisk are based on experiments with acids containing an amino-group. The dissociation constant of phenylarsinic acid is 0.027. In general, the two tables exhibit a close similarity, the marked divergences occurring in cases where the substituent is in the ortho-position to the carboxyl or arsenic group.

The conductivity of a substituted arsenic acid depends therefore on that of the parent acid, on the nature and position of the substituent (the effect is the same on the arsenic as on the carboxyl group provided that the groups are not too close to one another, in which case an additional factor enters), and on the immediate mutual action between acid radicle and substituent. The latter action is more marked in the arsenic than in the carboxylic series. In the latter, an increasing influence of the substituent is invariably observed as it more closely approaches the carboxyl group; the mutual action of the groups is not sufficiently great to overpower the effect of propinquity. The anomalies in the conductivity of di-ortho-substituted carboxylic acids, however, show that such mutual influence does exist. Possibly it is more marked in the arsenic acids by reason of the relatively greater arsenic residue,  $\text{O:As} \begin{smallmatrix} \text{OH} \\ \text{OH} \end{smallmatrix}$

H. W.

**The Crystalline Form of some Organic Derivatives of Arsenic.** G. GILTA (*Bull. Soc. chim. Belg.*, 1923, **32**, 19–26).—A detailed crystallographic examination of *p*-aminophenylarsinic acid and of the pentahydrate of its sodium salt (cf. A., 1922, i, 961). Acid: monoclinic [ $a:b:c=1.393499:1:1.162276$ ,  $\beta=101^\circ 20'$ ]. The effect of conditions on the predominant forms (including a twin) is discussed. Sodium salt pentahydrate: monoclinic [ $a:b:c=2.181215:1:0.960163$ ,  $\beta=91^\circ 4'$ ]; measurements are also given of a crossed twin. Tri- and di-hydrates of the sodium salt have been obtained but not measured.

E. E. T.

**Crystalline Form of Atoxyl [Sodium *p*-Aminophenylarsinate] and its Characterisation using the Microscope.** J. MÉLON (*Bull. Acad. roy. Belg.*, 1922, [v], **8**, 150–158).—A detailed crystallographic examination of atoxyl ( $+4\text{H}_2\text{O}$ ): monoclinic,  $a:b:c=0.986590:1:1.251538$ ,  $\beta=82^\circ 5'$  (cf. A., 1922, i, 961, and preceding abstract).

E. E. T.

**Arsenated Benzophenone and its Derivatives. II.** W. LEE LEWIS and H. C. CHEERTHAM (*J. Amer. Chem. Soc.*, 1923, **45**, 510–515; cf. A., 1922, i, 187).—By means of the Friedel and Crafts' reaction dichloro-*o*-arsinobenzoyl chloride has been condensed with a number of aromatic hydrocarbons and aromatic ethers to give new benzophenone arsenic acids. These compounds are easily and quantitatively reduced in acetic acid solution by concentrated hydrobromic or hydriodic acids to derivatives of arsenious oxide. In some cases, the reaction goes further, coloured crystalline

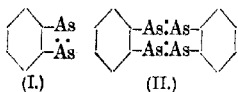

dibromo- or di-iodo-arsines being formed. The latter are easily converted again into the oxide by hydrolysis with dilute sodium carbonate. If the arsenic acids or, better, the arsenious oxides are heated under a reflux condenser with phosphorous acid in alcoholic solution, arseno-derivatives are obtained. The following new compounds are described: *Dichloro-o-arsinobenzoyl chloride*,  $\text{AsCl}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{COCl}$ , *benzophenone-2'-arsinic acid*,  $\text{C}_6\text{H}_4 \cdot \text{AsO}_3\text{H}_2$ , *4-methylbenzophenone-2'-arsinic acid*,  $\text{C}_6\text{H}_4\text{Me} \cdot \text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{AsO}_3\text{H}_2$ , *4-methoxybenzophenone-2'-arsinic acid*,  $\text{C}_6\text{H}_4(\text{OMe}) \cdot \text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{AsO}_3\text{H}_2$ , *4-phenoxybenzophenone-2'-arsinic acid*,  $\text{C}_6\text{H}_4(\text{OPh}) \cdot \text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{AsO}_3\text{H}_2$ , *4:4'-dibenzoylarsenobenzene*,  $2:2'$ -di-*p*-anisoylarsenobenzene,  $4:4'$ -diethoxybenzoyl- $2:2'$ -arsenobenzene,  $4$ -methoxybenzophenone- $2'$ -dibromoarsine,  $\text{OMe} \cdot \text{C}_6\text{H}_4 \cdot \text{CO} \cdot \text{C}_6\text{H}_4 \cdot \text{AsBr}_2$ , m. p.  $161^\circ$ ,  $4$ -ethoxybenzophenone- $2'$ -dibromoarsine, m. p.  $152^\circ$ ,  $4$ -methoxybenzophenone- $2'$ -arsenious acid,  $4$ -methoxybenzophenone- $2'$ -dichloroarsine, m. p.  $148^\circ$ ,  $4$ -methoxybenzophenone- $2'$ -di-iodoarsine, m. p.  $137^\circ$ ,  $4$ -ethoxybenzophenone- $2'$ -di-iodoarsine, m. p.  $151^\circ$ ,  $4$ -methoxybenzophenone- $4'$ -dichloroarsine, m. p.  $152^\circ$ ,  $4$ -methoxybenzophenone- $4'$ -dibromoarsine, m. p.  $136^\circ$ ,  $4$ -methoxybenzophenone- $4'$ -di-iodoarsine, m. p.  $105^\circ$ ,  $4$ -methoxybenzophenone- $4'$ -arsinoacetic acid. *Acetophenone-p-arsinic acid* is obtained when *p*-aminoacetophenone is diazotised and the product is treated with a solution of sodium arsenite. W. G.

**Silver Salvarsan.** WILLIAM HERBERT GRAY (T., 1923, 123, 635—642).

#### Aromatic Diarsinic Acids and their Reduction Products.

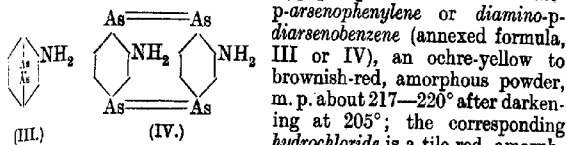

II. H. LIEB and O. WINTERSTEINER (Ber., 1923, 56, [B], 425—433).—In a previous communication (Lieb, A., 1921, i, 696), it has been shown that *m*- and *p*-phenylenediarsinic acids are reducible by phosphorous acid in sealed tubes at an elevated temperature to yellow, amorphous substances of the composition  $(\text{C}_6\text{H}_4\text{As}_2)_n$ , the molecular weight of which could not be determined on account of their insolubility in all suitable media. It is now found that the reduction can be more conveniently effected in open vessels by hypophosphorous acid. With the object of obtaining sufficiently soluble compounds, the observations have been extended to a number of derivatives, none of which, however, fulfils the required conditions.

*o*-Phenylenediarsinic acid is converted by hypophosphorous acid (d 1.28) into *o*-arsenophenylene or *o*-diarsenobenzene (annexed formulæ I or II), an egg-yellow, amorphous precipitate.

*o*-Nitroaniline is transformed by an equimolecular quantity of arsenic acid at  $210^\circ$  into a mixture of 3-nitro-4-aminophenylarsinic acid (cf. Mameli, A., 1909, i, 980; Berthelm, A., 1911, i, 1055) and di-3-nitro-4-aminophenylarsinic acid (Fargher, T., 1919, 115, 982). The former acid is converted by diazotisation and treatment with sodium arsenite in the presence of a little ammoniacal copper sulphate solution into 2(3)-nitrophenylene-*p*-diarsinic acid, colour-

less, pointed prisms, decomp.  $239-243^{\circ}$ ; the corresponding zinc and sodium salts are described. The acid is reduced by sodium amalgam in the presence of methyl alcohol to 2(3)-amino-p-phenylenediarsinic acid, long, oblique prisms which can be obtained only with difficulty in the colourless condition; the zinc salt is described. The nitro-acid is transformed by hypophosphorous acid into amino-

p-arsenophenylene or diamino-p-diarsenobenzene (annexed formula, III or IV), an ochre-yellow to brownish-red, amorphous powder, m. p. about  $217-220^{\circ}$  after darkening at  $205^{\circ}$ ; the corresponding hydrochloride is a tile-red, amorphous precipitate which decomposes gradually when heated above  $220^{\circ}$ . 2(3)-Methyl-p-phenylenediarsinic acid is prepared by the action of sodium arsenite on a diazotised solution of 4-amino-3-methylphenylarsinic acid; it crystallises in colourless leaflets which darken at  $280^{\circ}$  and decompose at  $330^{\circ}$ ; its properties are considerably affected by the presence of small amounts of organic and inorganic impurities, from which it is conveniently freed through its magnesium salt, a white, amorphous precipitate; the sodium salt ( $+9H_2O$ ) and the amorphous barium salt,  $C_7H_5O_6As_2Ba$ , are also described. The acid is reduced by hydrogen sulphide to the sulphide,  $C_6H_3Me(AsS)_2$ , a pale yellow, amorphous precipitate, and by phosphorous acid at  $190^{\circ}$  to methyl-p-arsenophenylene or dimethyl-p-diarsenobenzene, a yellow, amorphous compound which is readily re-oxidised to the diarsinic acid.

H. W.

## Physiological Chemistry.

**Comparative Studies on Respiration. XXIII. The Effect of Adrenaline on the Production of Carbon Dioxide by Animals and by Plants.** DOROTHY M. HUTCHINSON (*Amer. J. Physiol.*, 1922, 62, 192—196).—Carbon dioxide production was measured by the method of Osterhout (*J. Gen. Physiol.*, 1918, 1, 17). Adrenaline has similar effects on the respiration of frog's muscle and of radish seedlings. Stronger solutions (0.002 to 0.003%) cause a depression, followed by a return to normal, probably as the adrenaline is oxidised. Weaker solutions (0.002 to 0.005%) produce a rhythmic effect; the rate of carbon dioxide production falls, rises, then falls and rises again.

CHEMICAL ABSTRACTS.

**The Mineral Constituents of Blood.** A. DESGREZ and J. MEUNIER (*Compt. rend.*, 1923, 176, 608—611).—A spectrographic analysis of the fractions obtained by crystallisation of the soluble portion of the ash of blood and of serum was made, the photographs being taken on panchromatic plates, and the salts heated in the

hydrogen flame. The first crystal fraction consisted mainly of sodium chloride with traces of potassium. In the next fractions, the potassium line 404 was very pronounced, and the presence of lithium was clearly indicated by the line 670. In the last fractions, the lithium line was as intense as the sodium line 588. The amount of lithium present was estimated at about 1/500 of that of sodium.

G. F. M.

**Blood Studies in the Newborn. Morphological, Chemical, Coagulation, Urobilin, and Bilirubin.** W. P. LUCAS, B. F. DEARING, H. R. HOOBLER, A. COE, M. R. JONES, and F. S. SMYTH (*Amer. J. Diseases Children*, 1921, 22, 525—529).—The blood content of non-protein nitrogen, urea nitrogen, uric acid nitrogen, creatinine nitrogen, sugar, and carbon dioxide has been determined for the first twelve days of life. For this period, the calcium content of the whole blood, corpuscles, and plasma averaged, respectively, 8.8, 5.0, and 12.3 mg., respectively, per 100 c.c. for boys and girls together. During the first four days the coagulation time is definitely increased and the prothrombin element distinctly diminished. Urobilin or urobilinogen could not be found in the faeces. The estimation of bilirubin in plasma was carried out by adding 3 c.c. drop by drop to a solution of 30 c.c. of concentrated hydrochloric acid in 2 litres of 95% ethyl alcohol, and diluting to 25 c.c. On keeping, an emerald-green colour appears, developing greatest intensity in twenty-four hours. Comparison is made in a Hellige colorimeter with a wedge of gelatin, copper sulphate, and India ink, standardised with bilirubin. Eighty-two cases out of ninety gave a positive bilirubin reaction, the average curve beginning with 5 mg. of bilirubin per 100 c.c. of plasma, rising on the third day to 21 mg., and falling on the fourteenth day to 8 mg., although the actual quantities vary with different individuals.

CHEMICAL ABSTRACTS.

**Physiology of the Glands. LIV. Proof of Adrenaline in the Arterial Blood of Animals.** LEON ASHER and CARLO SCHNEIDER (*Biochem. Z.*, 1922, 133, 373—390).—A biological proof is given of the presence of adrenaline in the general circulation.

W. O. K.

**Production of Methæmoglobin by Narcotics.** PH. ELLINGER and FRANZ ROST (*Arch. exp. Path. Pharm.*, 1922, 95, 281—290).—The darkening of arterial blood which occurs during ether or chloroform narcosis is due to the formation of methæmoglobin.

E. S.

**Blood Clotting. V. Alexander Schmidt's Thrombin.** BERNHARD STUBER and MINORU SANO (*Biochem. Z.*, 1922, 134, 239—249).—With a thrombin solution prepared by Schmidt's method and a fibrinogen solution prepared by Hammarsten's method a number of observations were made which the authors consider prove that the action of thrombin is a pure swelling process, the fibrinogen simultaneously losing its solvent and thereby clotting. Thrombin solution completely freed from protein by various pre-

capitants or by dialysis cannot clot fibrinogen, and the smaller the protein content the longer is the period which elapses before clotting. Clotting time is dependent on the sodium chloride content of the fibrinogen, but is independent of its protein content. When thrombin and fibrinogen solutions of isotonic sodium chloride content were separated by a semipermeable diaphragm, clotting was observed to occur after many hours, even if the thrombin was replaced by gelatin or starch. This is interpreted as being due to the swelling of the partly denatured thrombin at the expense of the fibrinogen which loses its water and clots. H. K.

**Blood Clotting. VI. Mode of Action of Thrombokinase.** BERNHARD STUBER and MINORU SANO (*Biochem. Z.*, 1922, 134, 250—259).—Thrombokinase was prepared by Morawitz's method from liver. A high temperature and the presence of oxygen produce a feebly active product. The action of thrombokinase is attributed to its effect in lowering surface tension. On keeping, its solutions become more acid and lose activity, the maximum activity being observed over the range  $P_H$  6 to 7. H. K.

**Blood Clotting. VII. The Rôle of Calcium.** BERNHARD STUBER and MINORU SANO (*Biochem. Z.*, 1922, 134, 260—268).—Oxalated plasma can be caused to clot by addition of strontium salts, but not by barium or magnesium. Calcium is therefore not essential. By means of Traube's viscostagonometer, the internal friction of plasma was determined with increasing oxalic acid content. Increase of the oxalic acid beyond the point of flocculation through neutralisation causes an increased internal friction, and hence an increased ionisation. The same is observed with citrated plasma, and in the region of high internal friction alcohol produces no precipitate. The results are interpreted on the basis that oxalated and citrated plasmas cannot clot owing to maximum ionisation of the fibrinogen-salt complex, and clotting by excess of calcium or strontium salts is due to a reversal of the ionisation of the complex. H. K.

**Adsorption of Protein Degradation Products by the Blood-corpuscles in vivo and in vitro.** B. SEARSKY (*Biochem. Z.*, 1923, 135, 21—31).—Using Bach's method (*A.*, 1917, i, 375) for the estimation of degradation products of protein, the author has investigated the fate of the parenteral administration of erepton and diphtheria toxin to rabbits. No trace of protein degradation product was found in the blood immediately after intravenous injection of erepton (3.5 g.) or toxin (35 c.c.), either in the serum or in the blood, but if the blood is heated to boiling the protein degradation products are recovered quantitatively. The same applies to experiments in vitro. The injected peptones are therefore immediately adsorbed by the corpuscles and the first act in the process of immunisation is the adsorption of the toxins by the corpuscles. H. K.

**The Glycogen Content of White Corpuscles.** L. HABERLANDT (*Biochem. Z.*, 1922, 134, 405—406).—The author suggests

an explanation of de Haan's (A., 1922, i, 484) inability to find an increased glycogen content of the leucocytes of serum exudates after intraperitoneal administration of starch or glucose. H. K.

**The Clinical Significance of the Estimation of Calcium in the Serum of Children, and Possible Errors in the Estimation.** B. KRAMER, F. F. TISDALL, and J. HOWLAND (*Amer. J. Diseases Children*, 1921, 22, 560—564).—The blood-serum of normal children contains 10—11 mg. per 100 c.c., and that of normal adults 9·7—10·8 mg. Changes were observed only in cases of tetany and renal insufficiency, there being more or less distinct diminution of calcium in both cases. Sources of error in the estimation include the presence of calcium in the nitric and trichloroacetic acids, and even distilled water, and in the filter-paper, the solubility of calcium oxalate in water, and the fact that its precipitation must be accomplished in the presence of both magnesium and phosphates. The presence of magnesium in serum and plasma cannot normally be regarded as a serious source of error. Calcium oxalate is best precipitated from a liquid of  $p_H$  5·2—6·2. CHEMICAL ABSTRACTS.

**Antiphenolase (Antilaccase).** A. BACH and W. ENGELHART (*Biochem. Z.*, 1923, 135, 39—45).—Rabbits were immunised by intravenous injections of a phenolase solution prepared from a fungus (*Lactarius vellereus*). The immune sera, produced, inhibited the oxidation of suitable substrates, guaiacol, or pyrogallol independently of the reaction of the medium, whereas normal sera failed to inhibit. The antiphenolase action is associated with the non-dialysable portion of the serum, and is completely destroyed by heating at 80° for thirty minutes. The question as to whether the antiphenolase action is due to a physical change of the immune sera or to production of a chemically defined anti-substances is undecided. H. K.

**The Effect of Codeine on the Digestion of Meat by Dogs.** EDWARD ZUNZ and ALEXIS DELCORDE (*Bull. Soc. chim. Belg.*, 1923, 32, 79—80).—Injections of codeine lengthen the stay, in the stomach, of cooked meat, which is less rapidly affected by the digestive juices. The effects are smaller than those produced by morphine and the other opium alkaloids. Codeine increases the proteoses and decreases the acid albumins in the stomach, similarly affecting the peptones and abiuretic compounds in the prepyloric portion. It does not, however, affect the subsequent contents of the small intestine, and has little effect on the amount of nitrogen present as ammonia-amine type. E. E. T.

**The Influence of Various Quinine Derivatives on the Fermentative Function of the Organism.** J. A. SMORODIN-ZEV and A. N. ADOVA (*Biochem. Z.*, 1923, 135, 128—141).—The authors have investigated the effect of the addition of quinine monohydrochloride, quinine acid sulphate, quinine-urea dihydrochloride, urea nitrate, sulphate, and hydrochloride on the tryptic digestion of casein. The two quinine salts inhibit the action of trypsin, but the quinine-urea complex accelerates the reaction.

The urea salts at dilutions between  $N/20$  and  $N/80$  accelerate the digestion, but urea itself is without action. H. K.

**Ferments of the Digestive Organs of the Bee.** E. SARIN (*Biochem. Z.*, 1923, 135, 59—74).—The distribution of a number of ferments in various sections of the intestinal canal of the bee was examined. Catalase, lipase, amylase, invertase, pepsin, trypsin, and chymosin were found in the stomach, but not in the honey-stomach, the little intestine, or the colon, with the exception of catalase, which was found in the colon in the latter half of winter. Emulsin, lactase, and inulinase were absent in all cases. H. K.

**The Invertase of the Intestinal Canal of the Bee.** E. SARIN (*Biochem. Z.*, 1923, 135, 75—84).—Some further experiments (see preceding abstract) have been carried out on the invertase of the bee. In April and the late autumn, invertase appears to be absent from the bee's stomach, honey at this period consisting mainly of invert-sugar. For the preparation of an active invertase water is best, but the product does not keep well. An extract made with equal parts of glycerol and water retains its activity for eleven months. H. K.

**Unit of Energetic Metabolism and Active Mass of the Organisms.** EMILE F. TERROINE, A. FEUERBACH, and E. BREXCKMANN (*Compt. rend.*, 1923, 176, 462—464).—Analyses of normal and starved subjects in the case of two species show that, although the weight of the animal may vary within wide limits, the nitrogen present expressed as a percentage of the body-weight is a constant. These results, when compared with those of other workers on animals of vastly different size, owing to the difference in species, show that the protein content of the species studied is practically identical. It is thus useless to attempt to establish any relationship directly and entirely between the intensity of metabolism and the protein content. W. G.

**The Influence on Metabolism of some Purine and Pyrimidine Bases.** F. P. UNDERHILL and H. F. FARRELL (*J. Metabolic Research*, 1922, 2, 107—111).—Solutions of caffeine, theobromine, uric acid, and of hypoxanthine when injected into fasting rabbits led to an augmented excretion of total nitrogen, creatine, and creatinine, indicating an increased protein katabolism.

CHEMICAL ABSTRACTS.

**The Influence of Benzyl Benzoate on Nitrogenous Metabolism.** G. T. PACK and F. P. UNDERHILL (*J. Metabolic Research*, 1922, 2, 73—105).—Investigations on dogs indicate that the therapeutic dose of benzyl benzoate for man is probably insufficient to disturb the normal nitrogenous metabolism; larger doses, however (i.e., 0.5 c.c. per kg. of body-weight), cause an increase of protein katabolism in dogs. The total output of nitrogen is increased, marked creatinuria occurs, and conjugated glycuronates appear in the urine, but creatinine metabolism is unmodified. The changes are probably due to benzyl alcohol. Benzyl succinate produces

less change in the normal nitrogenous metabolism of the dog than the other benzene derivatives investigated. The katabolic processes which ensue after the administration of these benzene derivatives are discussed theoretically.

CHEMICAL ABSTRACTS.

**Potassium in Animal Nutrition. I. Influence of Potassium on Urinary Sodium and Chlorine Excretion.** HARRY G. MILLER (*J. Biol. Chem.*, 1923, 55, 45—59).—Experiments on pigs have shown that the increased excretion of sodium and chlorine which follows the administration of a single large dose of potassium salts is not maintained, even when the inclusion of potassium salts in the diet is continued.

E. S.

**Potassium in Animal Nutrition. II. Potassium in its Relation to the Growth of Young Rats.** HARRY G. MILLER (*J. Biol. Chem.*, 1923, 55, 61—78).—Rats maintained on diets containing less than approximately 0.1% of potassium showed failure of growth. Subsequent increases in the potassium content of the diet produced no permanent improvement.

E. S.

**Hydrolysis of Higher Fats in Egg-secretion.** OTTO GLASER (*Biol. Bull. Marine Biol. Lab.*, 1922, 46, 68—74).—*Arbacia* egg-secretion has the power to hydrolyse higher fats. Since whale oil, olive oil, and cetyl butyrate do not occur in sea urchin eggs, the lipase present must be non-specific. The lipolysin isolated by Woodward (cf. *J. Exp. Zool.*, 1918, 26, 459) appears to be, or contain, that enzyme which in unmodified egg-water is responsible for the hydrolysis of the higher fats.

CHEMICAL ABSTRACTS.

**Chemistry of the Lung. Nucleic Acids of the Lung.** UBALDO SAMMARTINO (*Biochem. Z.*, 1922, 133, 405—408).—A nucleic acid has been separated from lung tissue and purified by repeated precipitation as the copper salt. It has the formula  $C_{33}H_{54}O_{24}N_{10}P_2$ , and when hydrolysed with methyl-alcoholic hydrochloric acid yields adenine and guanine. No pentose could be detected.

W. O. K.

**Production and Destruction of the Cholesterol of the Spleen during Aseptic Autolysis.** SALVATORE MARINO (*Atti R. Accad. Lincei*, 1922, [v], 31, ii, 192—195).—The author confirms the observation of Abelous and Soula (*Compt. rend. Soc. Biol.*, 1920) that, during aseptic autolysis of the spleen, the cholesterol content at first increases and subsequently diminishes. The liver and brain show similar behaviour, but with the suprarenal and thyroid glands and the kidneys only destruction of the cholesterol occurs. These phenomena are functions of the temperature and time. It thus appears that, more than other organs, the spleen exerts a marked influence on the formation of cholesterol and on the metabolism of fats.

T. H. P.

**Creatine Content of Muscle in Anaërobic Contraction.** E. A. SPIEGEL and A. Löw (*Biochem. Z.*, 1923, 135, 122—127).—The creatine content of the gastrocnemius muscles of frogs is not altered by stimulating them to exhaustion either in Ringer solution or in air or nitrogen.

H. K.

**Acetaldehyde as an Intermediate Metabolic Product in Surviving Muscle.** JULIUS HIRSCH (*Biochem. Z.*, 1922, 134, 415—423).—In the aqueous distillate from the muscles of frogs, acetaldehyde was detected by Rimini's colour reaction. By the use of a fixative, dimethylhydroresorcinol, acetaldehyde was isolated from the surviving muscles of carp and tench. The breakdown of carbohydrates or lactic acid in the animal body appears to be by way of acetaldehyde. H. K.

**Manganese in Hair.** J. McCRAE (*J. S. African Chem. Inst.*, 1923, 6, 18—19).—The ash from 2.5 to 10 g. of hair was evaporated to dryness with dilute nitric acid, and the residue extracted with boiling water acidified with the same acid. To the filtered extract a few drops of dilute silver nitrate were added and then a small quantity of concentrated ammonium persulphate. Depending on the quantity of manganese present, a more or less deep pink colour is developed. It was matched by dilution of  $N/2000$  solution of potassium permanganate. Five samples of hair varying from fair to very dark were thus examined, and the quantity of manganese found to be of the order of 1 to 2 parts per million of hair. No relation with the colour was observed. The small proportion probably arises from the manganese in vegetable matter, which in turn is derived from that widely distributed in rocks and soil. T. S. W.

**The Reduction of Nitro-groups by Living Tissues.** N. WATERMAN and J. KALEFF (*Biochem. Z.*, 1923, 135, 174—181).—Lipschitz's results (*A.*, 1921, i, 203), on the reduction of *m*-dinitrobenzene by excised tissues and tumours, from which he draws important conclusions controverting the more direct results obtained by others with the Barcroft differential apparatus, are shown to be due to the use of impure *m*-dinitrobenzene, possibly containing thiophen derivatives. H. K.

**Calcium Content of Cats treated with Calcium.** W. HEEBNER and P. RONA (*Biochem. Z.*, 1923, 135, 248—281).—The minimum content of calcium oxide of the muscles, liver, brain, and kidneys of normal cats lies between 5 and 7 mg. of the weight when fresh; of the heart and small intestine 11 mg., lungs 16 mg., and colon between 25 and 30 mg. After repeated subcutaneous administration of calcium chloride solution (2 to 5%) the only organ showing increased calcium content is the kidney. H. K.

**The Inorganic Constituents of Marine Invertebrates.** FRANK WIGGLESWORTH CLARKE and WALTER CALHOUN WHEELER (*U.S. Geol. Survey*, 1922, Professional Paper 124, 1—62).—Quantitative analyses have been made of the inorganic constituents of a large number of marine invertebrates, and of marine algae. The results of previous analyses by other workers are also quoted in the paper, and the general results are discussed in their bearing more particularly on geological problems. W. O. K.

**Occurrence of Copper and Zinc in certain Marine Animals.** HAZEL W. SEVERY (*J. Biol. Chem.*, 1923, 55, 79—91).—Estimations have been made of the copper and zinc content of sixteen

different marine animals. Zinc was present in every case. Copper, however, was absent, or practically so, from the mammals (whale, sea-lion), and also from the clam. E. S.

**Is the Taste of a Salt due to the Ions or to the Whole Molecule?** H. KIONKA and F. STRÄTZ (*Arch. exp. Path. Pharm.*, 1922, **95**, 241—257).—Results obtained with the chlorides, bromides, and iodides of the alkali metals and ammonia indicate that the kation is mainly responsible for the intensity  
( $\text{NH}_4 > \text{Na} > \text{Li} > \text{Rb} > \text{Cs} > \text{K}$ )

and the anion for the quality of the taste. Neither quality nor intensity is appreciably altered by the presence of tasteless colloids (starch). Sodium chloride has a pure saline taste; all the remaining salts examined have mixed tastes, amongst which no fewer than twenty-five distinct tastes have been distinguished. E. S.

**Oxidation of Reduced Glutathione and other Sulphydryl Compounds.** MALCOLM DIXON and HUBERT ERLIN TUNN. CLIFFE (*Proc. Roy. Soc.*, 1923, [B], **94**, 266—297).—Experiments are described which show that the reduction of methylene-blue by reduced glutathione (this vol., i, 167), cystein, or thioglycollic acid are autocatalytic reactions in which the disulphide form of the sulphur compound acts as catalyst. This action is probably due to the formation of an additive compound between the sulphydryl and disulphide forms which is more active than the former alone. Acceleration of the reaction is also produced by surfaces such as glass-wool, kieselguhr, and platinum-black, provided care is taken to remove all traces of oxygen, and by direct sunlight. The oxidation of the sulphydryl compounds by atmospheric oxygen is similarly autocatalytic. In the cases of glutathione and cystein, the reaction velocity shows an optimum at  $P_H$  7.4; this, however, is not characteristic of sulphydryl groups, since it is not shown by thioglycollic acid. E. S.

**The Inorganic Phosphate content of Breast Milk of Mothers with Normal and with Rachitic Infants.** L. VON MEYSENBUG (*Amer. J. Diseases Children*, 1922, **24**, 200—203).—Average samples of the milk of mothers of non-rachitic and rachitic infants contain, respectively, 2.5—6.2 (average 4) mg. and 2.7—5.7 (average 4.8) mg. of inorganic phosphate per 100 c.c. The serum of non-rachitic and rachitic infants contained, respectively, 4.1—5.8 (average 5) mg. and 2.2—4.1 (average 2.8) mg. of inorganic phosphate per 100 c.c. CHEMICAL ABSTRACTS.

**Arginase. VII. Arginase in the Enteric Mucus and in the Enteric Secretion.** ANTONINO CLEMENTI (*Atti R. Accad. Lincei*, 1922, [v], **31**, ii, 559—561).—By the method previously described (this vol., ii, 271) the author demonstrates the absence of arginase from the intestinal secretion of the dog, the conclusion being drawn that arginase is not, as is sometimes assumed, an extracellular digestive enzyme participating in the digestion of proteins in the intestinal tract. On the other hand, this enzyme occurs in the intestinal mucus of the dog or monkey, probably

because it plays a part in the synthesis of homogeneous proteins from the products of digestion of heterogeneous proteins, this process being necessarily accompanied by partial destruction or elimination of certain amino-acids.

T. H. P.

#### **Behaviour of Cholesterol in the Blood and in the Kidneys.**

LOTHAR TIETZ (*Frankfurter Z. Pathol.*, 27, 353—367; *Ber. ges. Physiol.*, 15, 93; from *Chem. Zentr.*, 1923, i, 176).—The elimination of cholesterol in the urine appears to be independent of the amount present in the blood. Occurrence of cholesterol in urine implies deposition of fat in the renal parenchyma.

G. W. R.

**Elimination and Destruction of Uric Acid in the Human Body.** HEINRICH CHANTRAINE (*Biochem. Z.*, 1922, 133, 613—625).—It appears that fluctuations in the mechanism of elimination rather than of production are responsible for the variations in the daily excretion of uric acid. If uric acid is administered as the sodium salt, no destruction seems to take place, and approximately the amount administered is eliminated in the urine during the next three or four days, in addition to the normal elimination.

W. O. K.

**Analysis of the Urine Colouring Matters. III. Urochrome.** M. WEISS (*Biochem. Z.*, 1922, 133, 331—349).—Urochrome does not exist primarily in the urine as such, but as urochromogen, derived apparently from the destruction of cells. Urochromogen is the cause of the Ehrlich diazo-reaction. When oxidised, which is easily effected by atmospheric oxygen in alkaline solution, it is converted into the coloured compound urochrome, or into uromelanin.

W. O. K.

**Analysis of Urine Colouring Matters. IV. The Diazo-reaction of Urine and Urochromogen Excretion.** M. WEISS (*Biochem. Z.*, 1922, 134, 269—291).—The red colour produced in urine by Ehrlich's reagent is due almost entirely to urochromogen.

H. K.

**The Metabolism of Inorganic Materials in Diabetics. I.** ROBERT MEYER-BISCH and PAUL THYSSSEN (*Biochem. Z.*, 1923, 135, 308—316).—In four cases of diabetes mellitus the authors have estimated the calcium, dextrose, sodium chloride, sulphuric acid (free and bound) content and the alkali reserve of the blood after administration of 50 g. of sodium hydrogen carbonate. In each case the alkali reserve fell off, the other quantities showing little alteration, except calcium, which remains constant in normal persons but sometimes exhibits a temporary depression in a diabetic.

H. K.

**The Glycogen Content of the Tissues of Diabetic Animals and the Influence of Adrenaline thereon.** A. I. RINGER, H. DUBIN, and F. H. FRANKEL (*Proc. Soc. Exp. Biol. Med.*, 1921, 19, 92—97).—Between the second and seventh day of glycosuria, the muscles of fasting dogs given daily injections of phloridzin were found to contain on an average 482, 306, 228, 155, and 138 mg.

of glycogen per 100 g. Despite continuous fasting and complete diabetes, the muscle-cells retained a certain amount of residual glycogen. The muscles of similarly phloridzinised dogs, which had also been injected with adrenaline on the second or third day of glycosuria, contained the following amounts of glycogen in mg. per 100 g. one, three, and five days, respectively, after the adrenaline injection: 0; 20, 33, 23, 39; 69. In the case of dogs rendered glycogen-free and given glycogenetic substances, such as glycine, alanine, propionic acid, and lactic acid, the resulting glycosuria was not comparable to that found in dogs not treated with adrenaline. It is concluded that fasting diabetic dogs possess the power of glycogen formation after that substance has been eliminated from the muscles by the administration of adrenaline, and that failure of glycosuria is not a criterion of the glycogenetic quality of a substance, when given to deglycogenised diabetic animals.

CHEMICAL ABSTRACTS.

**Is there More Than One Kind of Rickets?** P. G. SHIPLEY, E. A. PARK, E. V. MCCOLLUM, and NINA SIMMONDS (*Amer. J. Diseases Children*, 1922, 23, 91—106).—There are two main kinds of rickets. In the one, the calcium content of the blood is normal, or nearly so, and the inorganic phosphorus content low, whilst in the other the relation is reversed.

CHEMICAL ABSTRACTS.

**Calcium and Phosphorus in the Serum in Relation to Rickets.** J. HOWLAND and B. KRAMER (*Amer. J. Diseases Children*, 1921, 22, 105—119).—For the estimation of inorganic phosphates, the blood-serum should not be left in contact with the blood clot. The inorganic phosphorus content of the serum of sixteen non-rachitic children varied from 4 to 7.1 mg. per 100 c.c. (average 5.4 mg.). For partly or wholly breast-fed infants, the range was 5.6—7.1 mg. (average, 6.1 mg.). The calcium content of the serum of fourteen cases of rachitic infants without signs of latent tetany varied from 8 to 10.8 mg. per 100 c.c.; the phosphorus content 0.6 to 3.2 mg., in four cases the magnesium content being 1.8—2.5 mg. In some cases, the administration of cod-liver oil caused a decided increase in the amount of inorganic phosphorus.

CHEMICAL ABSTRACTS.

**Calcium and Phosphorus Metabolism. I. The Excretion of Calcium and Phosphorus. II. The Metabolism of Calcium and Phosphorus in Rickets.** S. V. TELFER (*Quart. J. Med.*, 1922, 16, 45—62; 62—72).—I. The excretion of calcium, phosphorus, and their fatty derivatives is interdependent, calcium being eliminated chiefly as the phosphate and to a less extent as insoluble soaps. The total amount of calcium and phosphorus eliminated is nearly proportional to the intake; a large part of the ingested calcium is not absorbed, and appears in the faeces as normal calcium phosphate, only a small fraction of the total calcium being excreted in the urine. There is no evidence that any appreciable amount of endogenous calcium or phosphorus is eliminated. In normal infants, 40% of the total phosphorus excreted appears in

the urine and 60% in the fæces, but with acid formation in the intestine a greater proportion is excreted in the urine. The degree of deviation of phosphorus to the urine is roughly proportional to the amount of fatty acids in the fæces, and, therefore, to the degree to which fatty acids had displaced phosphoric acid from its normal combination with calcium in the intestine. An excess of calcium restricts an increased amount of phosphorus in the intestine. When the fat and phosphorus intake was low, an excess of calcium rendered the urine free from phosphorus. The average daily faecal weight depends chiefly on the degree to which calcium soaps are formed, since these form a mechanical basis for the formation of fæces. When the intake of both fat and phosphorus is very deficient, calcium may be excreted as carbonate. No evidence was found of the absorption of calcium and phosphorus in excess of requirements, with re-excretion into the intestine.

II. In normal infants on a diet of cow's milk the retentions of lime and phosphate were approximately equal. An excess of phosphate is retained over the equivalent amount of lime required for bone formation. In rickets, there is diminished retention of lime and phosphate, the latter being possibly due to diminished fixation by the calcium. No negative retentions of lime or phosphate were found, so that it does not appear that bone softening in rickets is due to excessive decalcification.

#### CHEMICAL ABSTRACTS.

##### The Mechanism of the [Physiological] Action of Chlorates.

RUDOLF L. MAYER (*Arch. expt. Path. Pharm.*, 1922, 95, 351—377).—In the presence of either ferrous sulphate or hæmoglobin, potassium iodide is oxidised by potassium chlorate. In both cases, the reaction is similarly influenced by variations in acidity, temperature, and concentration. The author concludes that the reduction of chlorates in the blood is a catalytic reaction in which hæmoglobin acts as catalyst by virtue of the iron which it contains. Hæmoglobin also catalyses the oxidation of sodium sulphite by potassium chlorate; when the sulphite is completely oxidised, the production of methæmoglobin commences. The latter can be partly reduced if more sulphite is added immediately, but if time is allowed to elapse, the reduction is more incomplete. Apparently the methæmoglobin changes from an active to an inert form. E. S.

Pharmacology of Selenium and Tellurium. IV. Action of their Acids on Trypanosomes in vitro. FRITZ LEHMANN (*Biochem. Z.*, 1922, 134, 390—397).—High concentrations of selenium or tellurium are lethal to trypanosomes, but after one hour's exposure the following dilutions were not lethal: for tellurites 1:500, for tellurates 1:300, for selenites 1:500, and for selenates 1:100. It was not found possible to obtain exact figures of toxicity. H. K.

Toxicity and Actions of the Normal Butylamines. P. J. HANZLIK (*J. Pharm. Expt. Ther.*, 1923, 20, 435—449).—The pharmacological actions of mono-, di-, and tri-butylamines have been

studied. All are toxic, and act as cardiac depressants; on the smooth muscle of excised organs, however, they exert a stimulant action, thus resembling histamine. When placed in an atmosphere saturated with the vapours of mono- and di-butylamines, white rats rapidly succumb; tributylamine, on the other hand, is insufficiently volatile to produce this effect.

E. S.

**The Effect of the Parenteral Administration of some Amino-acids on the Respiratory Gas Exchange of the Dog.** F. W. KRZYWANEK (*Biochem. Z.*, 1923, 134, 500—527).—The parenteral administration of alanine and of glycine causes a rise in the respiratory quotient and a negative nitrogen balance. The results of the author and of other investigators are discussed at length.

W. O. K.

**Pharmacological Properties of some isoUrea Derivatives.** STEWARD BASTERFIELD (*J. Pharm. Expt. Ther.*, 1923, 20, 451—461).—The *O*-ethyl derivative of allophanic ester,  $\text{NH}_2\text{C}(\text{OEt})\text{NH}\cdot\text{CO}_2\text{Et}$ , m. p.  $39^\circ$ , when injected into rabbits produced a moderate depression, a rapid fall of body temperature, and an increased muscle tonus. No great physiological action was shown by other iso-urea derivatives.

E. S.

**The Chemical Defence Mechanism of the Fowl.** JAMES H. CROWDLE and CARL P. SHERWIN (*J. Biol. Chem.*, 1923, 55, 15—31).—Various substances were fed to fowls. Benzaldehyde, phenylpropionic acid, and cinnamic acid were excreted as ornithuric acid; *p*-hydroxybenzaldehyde as *p*-hydroxybenzoic acid; *m*-nitrobenzaldehyde probably as the anhydride of *m*-aminobenzoic acid; nitrobenzene as *m*-aminophenol; *o*-nitrophenylpropionic acid as *o*-nitrobenzoic acid, and *m*-aminobenzoic acid as *m*-acetamidobenzoic acid. The fowl employs, apparently, processes of oxidation, reduction, acetylation, and conjugation with ornithine for the detoxication of these compounds, but is unable to form carbamide-compounds or to furnish glycine for this purpose.

E. S.

**The Active Alkaloids of Ergot.** H. H. DALE and K. SPIRO (*Arch. expt. Path. Pharm.*, 1922, 95, 337—350).—The physiological actions of the two alkaloids ergotoxine,  $\text{C}_{35}\text{H}_{41}\text{O}_6\text{N}_5$  (Barger and Carr, T., 1906, 94, 89), and ergotamine,  $\text{C}_{33}\text{H}_{35}\text{O}_5\text{N}_5$  (Spiro and Stoll, A., 1922, i, 47), isolated from ergot are qualitatively and quantitatively identical.

E. S.

**The Influence of the Parenteral Introduction of Protein on the Gas Metabolism.** ALFRED LEIMDÖRFER (*Biochem. Z.*, 1922, 133, 409—416).—Protein introduced parenterally into animals causes an increased oxidation in the tissues with a corresponding rise in temperature.

W. O. K.

**Effect of Pancreatic Extract (Insulin) on Normal Rabbits.** F. G. BANTING, C. H. BEST, J. B. COLLIP, J. J. R. MACLEOD, and E. C. NOBLE (*Amer. J. Physiol.*, 1922, 62, 162—176; cf. *Trans. Roy. Soc. Canada*, 1922, 16, V, 1).—When injected subcutaneously

into normal rabbits, insulin causes a diminution of the sugar content of the blood within a few hours, the animal exhibiting signs of hunger and thirst, hyperexcitability, and apparent fear, convulsive seizures often supervening, the sugar content of the blood then usually being about 0.045%. Subcutaneous injections of dextrose act as an antidote to the convulsions and other symptoms. Post-mortem examination frequently discloses a peculiar mucigenous degeneration of the subcutaneous tissues of the abdominal wall. As a basis for the physiological assay of insulin, the authors suggest as one unit the number of c.c. which cause the blood-sugar of normal rabbits to fall to 0.045% within four hours. This dose is decidedly active in lowering the sugar content of the blood in diabetic patients. CHEMICAL ABSTRACTS.

[Physiological] Effect of "Arsylene." S. KATZENELBOGEN (*Arch. internat. pharm. therap.*, 1922, 26, 407—420; from *Chem. Zentr.*, 1923, i, 173).—Arsylene (sodium allylarsinate) is less poisonous than arsenious oxide. With single administration of a large dose, no simple alteration in the composition of the blood is observed. Daily doses of 0.015 g. per kg. of live weight produce slight decrease in erythrocytes, irregular variation in leucocytes, increase in lymphocytes, and occurrence of isolated nucleated erythrocytes. Daily doses of 0.001—0.002 g. per kg. produce irregular increase in erythrocytes and hæmoglobin. The resistance of erythrocytes against hæmolysis is not increased by "arsylene." G. W. R.

**Experimental Acid Poisoning. II. The Respiratory Gas exchange in Acid Poisoning.** A. LOEWY and E. MÜNZER (*Biochem. Z.*, 1923, 134, 437—441).—The administration of hydrochloric acid to rabbits decreases the intake of oxygen as well as the output of carbon dioxide. The deleterious poisoning effects of the acid are therefore to be ascribed to a decrease in the rate of oxidation in the cell, as well as to the lowered capacity of the blood to transport carbon dioxide. W. O. K.

**Experimental Acid Poisoning. III. Does Methyl Alcohol poisoning Lead to an Acidosis?** A. LOEWY and E. MÜNZER (*Biochem. Z.*, 1923, 134, 442—446).—In acidosis, there is a change in the dissociation constant of the blood. Methyl alcohol is said to be oxidised to formic acid in the body, and the abnormal amount of ammonium salts in the urine following methyl alcohol poisoning is said to be a result of the acidosis. It is now shown that if methyl alcohol is administered to dogs or rabbits, any acidosis so induced is too weak to alter the dissociation curve of the blood. W. O. K.

**A Study of Metabolism in Chloroform Poisoning.** F. P. ANDERHILL and ROBERT KAPSINOW (*J. Metabolic Research*, 1922, 5, 57—72).—Graham's hypothesis (*J. Exp. Med.*, 1915, 22, 48) that in late poisoning with chloroform and with other alkyl halides the intoxication is due chiefly to the liberated hydrogen chloride was not confirmed. A diet yielding an alkaline ash when fed to

rabbits had no inhibiting effect on delayed chloroform poisoning. The excretion of chlorine by rabbits poisoned with chloroform was not increased in starvation. The only metabolic changes observed with the alkaline diet that could not be explained by the food were alterations in the creatinine, creatine, and total nitrogen excretion. These are probably the results of absorption of dead tissue following injury by chloroform. CHEMICAL ABSTRACTS.

## Chemistry of Vegetable Physiology and Agriculture.

**Influence of Copper on Lactic Fermentation.** MARC FOUASSIER (*Compt. rend.*, 1923, 176, 606—608).—The influence exercised on lactic fermentation by contact with certain metals either previously to, or during the action of, the ferment was studied. Lamellæ of the following metals, zinc, aluminium, lead, silver, iron, nickel, copper, and tin, were placed in contact with sterilised milk, which was then inoculated with the lactic ferment, and observations were made of the increase in acidity. It was found that this increase was more rapid in presence of iron, much retarded by copper, and uninfluenced by the other metals. The inhibiting action of the metallic copper on the fermentation was just the same, whether the metal was present during the fermentation or whether the milk had previously been exposed for eight hours to the metal, which was then removed before inoculation. The antiseptic action of copper was further demonstrated by the gradual loss in activity of the ferment suspended in pure sterile water in presence of a piece of copper foil. G. F. M.

**Bacteria which Split Nucleoprotein and their Importance for the Liberation of the Phosphorus Reserve in Surface Soils.** ALFRED KOCH and ALICE OELSNER (*Biochem. Z.*, 1922, 134, 76—96).—Phosphates are liberated from nucleoproteins and their breakdown products by various soil bacteria (nucleobacter). Chalk is suitable to the liberation of inorganic phosphate, as it gives an alkaline reaction favourable to the bacteria. For analyses of inorganic phosphate in presence of organically bound phosphorus, ammonium molybdate was found suitable, and ultra-filtration was employed for removing bacteria from nutrient media before analysis. H. K.

**The Chemotherapy of the Acridine Dyes in Experimental Tuberculosis.** MAURICE I. SMITH (*J. Pharm. Expt. Ther.*, 1923, 20, 419—434).—Certain acridine derivatives, namely, acriflavine, proflavine, acridinium-yellow, and acridine-orange, inhibit to a marked degree the growth of the tubercle bacillus in vitro. The pathogenicity of the bacillus is not, however, altered, neither is the tuberculosis process in experimentally infected animals modified by injections of these substances. E. S.

**Occurrence of *p*-Hydroxybenzaldehyde and *p*-Hydroxybenzoic Acid in the Bacterial Decomposition of Tyrosine, with Special Reference to Melanin Formation.** KINSABURO HIRAI (*Biochem. Z.*, 1923, 135, 299—307).—By the prolonged action of *Proteus vulgaris* on *l*-tyrosine in Ringer's solution, *p*-hydroxybenzaldehyde and *p*-hydroxybenzoic acid were formed in small yield. In addition, after three weeks a black colouring matter was produced, but not if the medium contained glycerol. The production of this melanin is favoured by use of Henderson's phosphate mixture as a nutrient medium, or by the presence of platinum sponge. The melanin is amorphous, but is soluble in alkali, alcohol, glacial acetic acid, acetone, or ethyl acetate. Its production is probably due to a tyrosinase, as under parallel conditions it is not formed from tryptophan, phenylalanine, or leucine.

H. K.

**Oxidation of Zinc Sulphide by Micro-organisms.** W. RUDOLFS and ANDRÉ HELBRONNER (*Soil Sci.*, 1922, 14, 459).—A culture of organisms was isolated which were capable of oxidising zinc sulphide to sulphate without suffering injury from the soluble zinc salt. The addition of elementary sulphur to an impure culture increased the rate of oxidation of zinc sulphide. The "Lipman" sulphur oxidising bacteria produce sufficient sulphuric acid to dissolve zinc carbonate and silicate. The possibility of a biological process for utilising low-grade zinc blendes is noted.

A. G. P.

**Cell Respiration. I. The Respiration of Yeast-cells.** P. RONA and K. GRASSHEIM (*Biochem. Z.*, 1922, 134, 146—162).—The optimum hydrogen-ion concentration, whether produced by phosphate or acetate buffer mixtures, for the respiration of yeast-cells (*Torula pulcherrima*) lies between  $P_H$  4.5 and 6.6. Just outside these limits, the respiration falls off considerably. The oxygen consumption, using acetates as buffers, is about 30% more than when using phosphates, the most favourable concentration of the latter being one-third molar. The respiration is affected by the age of the yeast, for it falls off after seven days; it is not, however, affected by repeated freezing and thawing of the yeast-cells.

H. K.

**The Transformation of Tertiary Amino-acids by Yeast.** K. KURONO (*Biochem. Z.*, 1922, 134, 424—433).—When a large amount of sucrose was fermented by yeast in the presence of *dl*-2-amino-2-methyl-*n*-valeric acid, the products isolated were the same amino-acid exhibiting *lævo*-rotation, and methylpropylcarbinol also exhibiting *lævo*-rotation. The identity of this alcohol was proved by preparation of its  $\alpha$ -naphthylurethane, m. p. 46°, by its oxidation to methyl propyl ketone, which gives a *p*-nitrophenylhydrazone, m. p. 112°. During the fermentation, it is therefore supposed that the degradation takes place via the ketone,  $\text{NH}_2\text{CRR}'\text{CO}_2\text{H} \rightarrow \text{CORR}' \rightarrow \text{CHRR}'\text{OH}$ .

H. K.

**The Behaviour of Pyruvic Acid and Acetaldehyde to Oxygenated Yeast.** FRITZ LIEBEN (*Biochem. Z.*, 1923, 135, 240—247).—Pyruvic acid as its sodium salt is partly decomposed with evolution of carbon dioxide and partly utilised by the yeast-cells for body building, when shaken with yeast-cells in a stream of oxygen. Acetaldehyde under similar conditions is for the most part unchanged. Pyruvic acid can be quantitatively estimated by Fürth and Charnass's method if it be first of all reduced to lactic acid by zinc dust and hydrochloric acid. H. K.

**The Oligodynamic Action of Metals.** JOSEF SCHUMACHER (*Biochem. Z.*, 1922, 134, 398—404).—Pure methylene-blue reduced to leucomethylene-blue by sodium formaldehydesulphoxylate can be used for detecting silver in oligodynamic quantities. Water in which a silver coin has been boiled restores the blue colour instantaneously, and immersion of the coin in a leucomethylene-blue solution gives rise to blue layers over the coin, whereas the main bulk of the solution remains colourless. H. K.

**The Influence of Hydrogen-ion Concentration on the Antiseptic Effect of Sublimate.** GEORG JOACHIMOGLU (*Biochem. Z.*, 1923, 134, 489—492).—The antiseptic effect of mercuric chloride disappears in weakly alkaline reaction between  $P_H$  7.8 and  $P_H$  10.1, and appears to be most marked in weakly acid reaction between  $P_H$  5.0 and  $P_H$  6.6. W. O. K.

**Formation of Oxygen from Carbon Dioxide by Protein-Chlorophyll Solutions.** M. EISLER and L. PORTHEIM (*Biochem. Z.*, 1923, 135, 293—298).—The filtrate from a 95% alcoholic extract of grass was treated with four volumes of twenty-fold diluted heteroserum and the flocculated precipitate collected by centrifuging. The protein-chlorophyll mixture was dissolved in 0.85% sodium chloride solution, and using a differential blood-gas apparatus the solution in one bulb was exposed to bright sunlight in an atmosphere of carbon dioxide. The bulb exposed to sunlight exhibited an excess pressure which analysis showed was due to liberation of oxygen. H. K.

**A New and Efficient Respirometer for Seeds and other Small Objects.** GEORGE T. HARRINGTON and WILLIAM CROCKER (*J. Agric. Res.*, 1923, 23, 101—116).—After discussing various types of respirometers, previously advocated, the authors describe a new form of respirometer, a sketch of which is given in the original. With this apparatus, oxygen consumption and carbon dioxide production are determined in the same apparatus and for the same period of time, using the whole volume of air instead of a sample. The gaseous exchanges are determined at the end of an experimental period by means of a manometer, which is an integral part of the apparatus. The pressure readings are made the basis of direct calculations, both of oxygen consumed and of carbon dioxide given off. W. G.

**Respiration of Apple Seeds.** GEORGE T. HARRINGTON (*J. Agric. Res.*, 1923, 23, 117—130).—Using the respirometer previously

described (preceding abstract), the author has made a study of the respiration of apple seeds under different conditions.

The respiratory intensity of dormant apple seeds is low, but the intensity in the case of seeds capable of germination is higher and becomes very high with advancing germination, but soon falls if the germinated seeds are kept at too high a temperature. Removal of the outer seed coats increases the respiratory intensity and accelerates germination, but does not affect the respiratory quotient. At the ordinary temperature, the respiratory quotient corresponds with complete oxidation of fats or only slight increase in sugars. With rise in temperature, there is an increase in the respiratory quotient, causing impoverishment in easily oxidisable substances, and with fall in temperature there is a fall in the quotient and a storage of oxygen which probably leads to an increase in acids and sugars. With a relatively high rate of oxidation at high temperatures, there is a tendency for the seeds to become dormant. With advancing germination, the respiratory quotient becomes low, indicating the rapid transformation of fats and accumulation of sugars, but this is preceded by a brief initial rise, which indicates that oxygen-rich substances are being broken up more rapidly than they are replaced.

Respiratory intensity, respiratory quotients, and temperature coefficients are affected by the previous treatment of the seeds, being higher after treatment which tends towards after-ripening, and lower after treatment which induces deeper dormancy. W. G.

**Ferment Formation in Germinating Plant Seeds.** A. BACH and A. OPARIN (*Biochem. Z.*, 1922, 134, 183—189).—The authors have estimated the content of respiratory ferments (catalase, peroxidase, oxygenase) and of hydrolytic ferments (amylase, protease) in germinating wheat grains and sunflower seeds. During germination, the content of ferments rises to a maximum in six to eight days except for catalase in wheat, which reaches its maximum in three to four days. The catalase content of sunflower seeds is greater than that of wheat, but the reverse is the case for the other ferments. H. K.

**The Influence of Oxygen on the Formation of Ferments in Germinating Wheat Grains.** A. OPARIN (*Biochem. Z.*, 1922, 134, 190—193).—Increased partial pressure of oxygen has no influence on the formation of ferments (preceding abstract) with the exception of oxygenase, which is inhibited, but replacement by an inert gas such as hydrogen is inimical to all ferments except oxygenase. H. K.

**Ammonia as Primary and End-product of Nitrogen Metabolism in Plants.** D. N. PRIANISCHNIKOV (*Landw. Versuchs-Stat.*, 1922, 99, 267—286).—The author further develops his earlier theories on the nitrogen metabolism of plants. In seedling plants receiving ammonium salts, the changes depend on the amount of carbohydrates present. Where, as in barley and maize, abundant carbohydrate is present, asparagine is formed and comparatively little ammoniacal nitrogen is found. Where, as in

lupines, the proportion of carbohydrate to protein is less, more ammoniacal nitrogen is found, and the formation of asparagine is depressed. By artificially decreasing the amount of carbohydrate, either by starvation or by removal of cotyledons or endosperm, plants rich in carbohydrate can be made to behave in the same way as those poor in carbohydrate. Similarly, by supplying dextrose to lupine seedlings, increased formation of asparagine and decrease in ammoniacal nitrogen may be induced. Asparagine is held to fulfil the same function in plant metabolism as carbamide in animal metabolism.

G. W. R.

**The Chemical Mechanism of the Formation of Fat in the Living Cell.** HUGO HAEHN and WALTER KINTROP (*Ber.*, 1923, 56, [B], 439—445).—A preliminary communication. It has been suggested previously (Haehn, *Z. tech. Biol.*, 1921, 9, 217) that acetaldehyde is an intermediate product in the conversion of carbohydrates into fats within the living cell, and that the process occurs in accordance with the scheme: dextrose  $\rightarrow$  pyruvic acid  $\rightarrow$  acetaldehyde  $\rightarrow$  aldol  $\rightarrow$  glyceryl ester. It is suggested that aldol is transformed into  $\gamma$ -dihydroxy-*n*-hexaldehyde or the corresponding unsaturated substance, which is converted by successive oxidation and reduction into sorbic and hexoic acids. Condensation of three molecules of the unsaturated aldehyde leads to the production of the carbon chain of oleic and stearic acids, whereas that of palmitic acid is derived from two molecules of hexaldehyde and one molecule of aldol. In the present communication, it is shown that the assumed intermediate products are assimilated by the cell, and that the presence of certain of them can be established by suitable methods.

*Endomyces vernalis* is grown in a normal culture solution which is replaced as soon as the mycelium is developed by pure solutions of acetaldehyde, pyruvic acid, or aldol, respectively, which are adjusted to  $P_H$  6.8 by potassium hydrogen phosphate. In every case, the appearance of fat within the cells is noticed within twenty-four hours. Similar observations are recorded with maltose. The process of fat formation probably occurs in two phases, in the first of which the sugar is converted by zymase through pyruvic acid into acetaldehyde, probably in accordance with Neuberg's scheme of alcoholic fermentation; the hypothesis receives support from the observation that carbon dioxide is freely evolved, whereas the presence of ethyl alcohol cannot be detected. In the second phase, the synthesising enzymes, probably of the carboligase type, cause the formation of fat from the acetaldehyde.

The formation of acetaldehyde as intermediate product has been demonstrated by the aid of the sulphite process; in experiments in which the acetaldehyde is thus fixed, the production of fat is very small. The yields of acetaldehyde correspond approximately with those obtained by Neuberg in experiments with moulds.

For the estimation of fat, the mould is dried at  $100^\circ$  and cautiously heated in an iron crucible with water and solid potassium hydroxide. The molten mass is cooled, dissolved in water, and acidified

with sulphuric acid. The free fatty acids are extracted with light petroleum, dissolved in alcohol, and titrated with alcoholic potassium hydroxide solution; the results are expressed as triolein. H. W.

**The Genesis of Peroxydase in Plants. Conditions determining Fission of Peroxydase from the Protoplasts and Liberation in the Cell-juice.** W. PALLADIN and (FRL.) S. MANSKAJA (*Biochem. Z.*, 1923, 135, 142—157).—Using the colour reaction given by peroxydase with guaiacum-resin or guaiacol and hydrogen peroxide, peroxydase is found in the cell-sap, but also found in the protoplasts. During autolysis, the peroxydase is split off from the protoplasts, and especially so in the presence of salts. The results are interpreted in terms of Ehrlich's side-chain theory, the postulated existence of pro-ferments being unnecessary. Peroxydase is also found in the woody fibre of the beech. H. K.

**The Constituents of Green Plants. XXIII. Malic Acid in Plants.** HARTWIG FRANZEN and ERNST KEYSSNER (*Biochem. Z.*, 1923, 135, 183—216).—A critical review of the whole of the available literature on the occurrence of malic acid in plants leads to the conclusion that, contrary to general opinion, the wide distribution of malic acid is untenable. The proof of the identity of this acid is insufficient in numerous cases. H. K.

**Identity of the Sugar Extracted from the Manna of the Carob Tree with Pinitol or Methyl-d-inositol.** C. CHAUAUX (*Bull. Soc. Chim. biol.*, 1922, 4, 597—600).—An exudation found on the trunk of the carob tree (*Ceratonia siliqua*, L.) yielded 84% of pinitol when extracted with alcohol. E. S.

**The Prolamine of *Coix lacryma*, L.** GISABURO HATTORI and SHIGERU KOMATSU (*J. Biochem. [Japan]*, 1922, 1, 365—369).—Kernels of *Coix lacryma*, L., gave: Water 12.33, ash 7.06, protein nitrogen 2.92, crude protein 18.68, crude starch 50.66, soluble non-nitrogenous matter 4.93, crude fat 4.69, and crude fibre 7.42%. Coicine was prepared by extracting the meal with 80% alcohol at 78° and after further purification formed a yellowish-brown powder containing 0.6% of ash. The distribution of nitrogen in the pure prolamine was determined by the method of Osborne and Harris (*J. Amer. Chem. Soc.*, 1903, 22, 323) as follows: Humin nitrogen 0.1%, ammonia nitrogen 3.32%, basic nitrogen 0.94%, non-basic nitrogen 0.23%, monoamino-nitrogen 5.50%, imino-nitrogen 6.95%, total nitrogen 16.84. Determinations of the amino-acids gave glutamic acid 20.65%, leucine 4.10%, tyrosine 1.46%, arginine 0.20%, histidine 1.88%, and lysine 0.76%. K. K.

**The Influence of Hexamethylenetetramine and Formaldehyde on the Internal Morphology and the Chemistry of the Haricot Bean.** E. NICOLAS and G. NICOLAS (*Compt. rend.*, 1923, 176, 404—407).—Both hexamethylenetetramine and formaldehyde in small doses are nutrients for the haricot bean. They cause, not only an increase in the weight of the plant (cf. this vol., i, 77) and a great development of leaf surface, but they are used, in addition,

for the differentiation and even lignification of the wood and of the pericycle, as well as for the formation of starch. W. G.

**The Changed Content of Urea in the Ripening of the Fruit of *Lycoperdon*.** NICOLAUS N. IVANOV (*Biochem. Z.*, 1923, 135, 1—20).—During ripening of *Lycoperdon gemmatum* (Puff-ball) there is a disappearance of carbohydrate (trehalose) and accumulation of nitrogen from 7.1 to 8.7%. The urea content increases during ripening, but disappears from the spores. The urea appears to be in the combined state, as it is not extracted by alcohol in an extractor, but is so by hot water. The urea probably functions as a reserve substance for the synthesis of arginine and purine bases, and for the production of ammonia used in building up tissue. H. K.

**Microchemical Researches on Coumarin.** ALBERT NAVEZ (*Bull. Acad. roy. Belg.*, 1922, [v], 8, 159—173).—From the fact that tannins can be localised by microchemical methods in *Melilotus albus* and *M. altissimus* in the same regions as the glucoside discovered by Bourquelot and Hérissé (A., 1920, i, 586), it is considered likely that the glucoside (coumarigenin), which is derived from dextrose and coumarin hydrocoumarate, is combined, in the plant, with a second glucoside, melilotannic acid, derived from melilotic acid and tannin. E. E. T.

**Quantitative Composition of Coniferous Wood.** ASTRID CLEVE VON EULER (*Cellulosechem.*, 1923, 4, 1—11).—The mineral constituents, the protein, and the fat-resin components are regarded as not belonging to the true wood substance, and the analytical results are calculated, with the exclusion of these, in terms of carbohydrates and lignin. To the lignin belongs the so-called "alcohol resin," which is regarded as a lignin derivative soluble in alcohol. This is estimated, after removal of the fat and oleo-resin by extraction for six hours in benzene, by a further extraction with 96% alcohol for twenty-four hours. It is extracted very slowly, and the dried alcoholic extract is not completely soluble in alcohol. In the estimation of the lignin by hydrolysis of the carbohydrates with 72% sulphuric acid, the result is always higher than when 40% hydrochloric acid is used, owing to the combination of sulphuric acid groups with the lignin. A correction of 5.7 units should be deducted from the lignin value found by the sulphuric acid method. By both methods, the acetyl group is eliminated from the lignin as the result of hydrolysis, and this is compensated by adding 2.0 units to the percentage of lignin found. All results are then calculated in terms of the pure wood substance, the "alcohol resin" being added to the insoluble lignin under the designation of lignin soluble in alcohol. The lignin value of the wood is not a specific constant, but varies within limits according to the origin of the sample. Recalculated on the above principle, the analysis published by Klason in 1921 becomes: Cellulose, 54.10; hemicelluloses comprising hexosans, 3.06, and pentosans 12.25; total carbohydrates, 69.40%; lignin, including the acetyl group, 30.60%. J. F. B.

## Organic Chemistry.

**The Pyridine Extract of Upper Silesian Coal : Preliminary results.** II. F. HOFMANN and P. DAMM (*Brenstoff-Chem.*, 1923, 4, 65—73; *ibid.*, 1922, 3, 73).—In the fraction of the "neutral oil" boiling above  $300^{\circ}$  at ordinary pressures, paraffins, other saturated hydrocarbons, and unsaturated hydrocarbons were found to be present. The first were for the most part separated by treatment with acetone in which they were much the least soluble. The last two could not be satisfactorily separated by liquid sulphur dioxide, but were so by means of methyl alcohol, in which the unsaturated hydrocarbons alone were soluble. The insoluble saturated hydrocarbons were treated with acetone at  $0^{\circ}$  and at  $-18^{\circ}$  to separate any paraffins still present. Five hundred kg. of coal gave 42 kg. of pyridine extract containing 82 g. of paraffins, 332 g. of other saturated hydrocarbons, and 769 g. of unsaturated hydrocarbons. All the hydrocarbons were purified by recrystallisation and distillation at low pressures, alone and over sodium in a current of carbon dioxide. The unsaturated hydrocarbons received, in addition, treatment with methyl sulphate in which they were soluble.

There were identified in the paraffinoid portion: the hydrocarbons  $C_{21}H_{44}$  to  $C_{27}H_{56}$  inclusive. Evidence was obtained that a hydrocarbon separated by Pictet (A., 1916, i, 800) from a benzene extract of a coal, which he identified with Brodie's melene, was probably a mixture of the above paraffins. The other saturated hydrocarbons present appeared to be  $C_{17}H_{36}$ ,  $C_{17}H_{28}$ ,  $C_{18}H_{28}$ ,  $C_{19}H_{30}$ ,  $C_{22}H_{38}$ ,  $C_{23}H_{38}$ , and  $C_{24}H_{40}$ , but these formulæ are given with reserve owing to the difficulty of deducing definitely the number of hydrogen atoms present in a molecule of these hydrocarbons from the analytical figures. They are probably partly reduced and partly substituted polynuclear aromatic hydrocarbons.

The unsaturated hydrocarbons were also difficult to place, determinations of the refractive index giving no satisfactory aid. The following appeared to be present:  $C_{18}H_{20}$  (a partly reduced and alkyl-substituted naphthalene derivative),  $C_{16}H_{20}$ ,  $C_{17}H_{22}$ ,  $C_{18}H_{22}$ ,  $C_{19}H_{24}$  (partly reduced and substituted anthracene and phenanthrene, etc., derivatives),  $C_{21}H_{26}$  (a partly reduced and substituted tetranuclear derivative. Methylanthracene,  $C_{15}H_{12}$ , was definitely isolated among these hydrocarbons. T. S. W.

**The Preparation of True Acetylene Hydrocarbons.** M. BOREGUEL (*Compt. rend.*, 1923, 176, 751—753).—The difficulties encountered in the preparation of pure acetylenes by the action of potassium or sodium hydroxide on halogen derivatives of saturated hydrocarbons are largely avoided by eliminating the hydrogen halide by means of finely powdered sodamide suspended in benzene or xylene. No isomerisation or polymerisation occurs, and the

true acetylene hydrocarbon is almost the sole product owing to the automatic formation of the sodium derivative, which after removal of the diluent is decomposed by the addition of ice and a mineral acid. The preparation of *n*-pentinene,  $C_5H_7 \cdot CH_2 \cdot C \equiv CH$ , b. p.  $39.6-40^\circ$ , and of  $\gamma$ -phenylpropinene,  $C_6H_5 \cdot CH_2 \cdot C \equiv CH$ , b. p.  $69.5-70^\circ/18$  mm., by this method is described, and also of methyl propargyl ether,  $CH_3 \cdot O \cdot CH_2 \cdot C \equiv CH$ , b. p.  $63^\circ$ , from  $\beta$ -dibromopropyl methyl ether, and ethyl propargyl ether,  $C_2H_5 \cdot O \cdot CH_2 \cdot C \equiv CH$ , b. p.  $79.5-80^\circ$ , from the corresponding dibromopropyl ethyl ether. Phenylacetylene was obtained in a pure condition, b. p.  $140.5-141^\circ$ , from styrene dibromide and sodamide. G. F. M.

**Spinacene : its Oxidation and Decomposition.** A. CHASTON CHAPMAN (T., 1923, 123, 769-779).

**Compounds of Aluminium Bromide with Phosphorus Bromides and Organic Bromides.** V. A. PLOTNIKOV (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1891-1896).—A compound,  $AlBr_3 \cdot PBr_5 \cdot EtBr$ , is obtained by the addition with cooling of a solution of phosphorus pentabromide in ethyl bromide to a similar solution of aluminium bromide. This compound is, unlike its constituents, stable above  $150^\circ$ , decomposition occurring at  $230^\circ$ , with evolution of hydrogen bromide and formation of some pentabromoethane. The complex is immediately decomposed by water, in which it is completely soluble, and the entire bromine content may be precipitated by silver nitrate, ethyl alcohol being identifiable in the solution. A similar compound,  $AlBr_3 \cdot PBr_5 \cdot EtBr$ , m. p.  $160^\circ$  (decomp.), may be obtained by substituting phosphorus tribromide for the pentabromide in the above reaction, whilst a third compound,  $AlBr_3 \cdot PBr_3 \cdot CMeBr_2$ , m. p.  $134^\circ$ , may be obtained by substituting ethylidene dibromide for ethyl bromide. Aluminium bromide and phosphorus pentabromide, if mixed in carbon disulphide solution, form a compound,  $AlBr_3 \cdot PBr_5$ , decomposing at  $100^\circ$ . R. T.

**The Structure of Complex Compounds.** V. A. PLOTNIKOV (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1896-1905).—The structure of complexes of ethyl bromide with the bromides of aluminium and phosphorus, such as  $AlBr_3 \cdot PBr_5 \cdot EtBr$  (preceding abstract), is discussed. The combination of molecules to form complexes is explained as being due to the action of electrons contained in the various atoms of the molecule, and the molecules combined together to form a complex exert a profound influence on each other. The result of this is to increase the reactivity of these groups, and, if molecules of water enter the complex, hydrolysis of its constituents takes place with abnormal rapidity and completeness. R. T.

**The Isomeric Transformations of Halides of Alcohols, and of Sulphovinic Acids leading to the Regrouping of Carbon Atoms.** A. E. FAVORSKI (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 43-80).—Various examples of intramolecular rearrangement of organic compounds are studied, in particular those of halogen derivatives of hydrocarbons. From these, it is concluded that a

dition of strain may exist between carbon-carbon linkings, which may, in favourable circumstances, lead to dissociation. This tendency is weakest with triple linkings, and strongest with single ones. For saturated compounds, it is most marked in cyclic groupings, and with open-chain compounds between quaternary carbon atoms, i.e., those joined to four others, as in tetraphenylmethane or hexaphenylethane. Tertiary carbon atoms joined to other atoms multiply bound, will often undergo rearrangement, leading to the transposition of radicles. The mobility of radicles attached to tertiary carbon atoms depends, not only on the condition of strain of the bonds, but also on the degree of interaction between the radicles themselves.

[With NADESHDA SAKARA.]—The acetate of  $\beta\beta$ -dimethylbutyl alcohol has b. p.  $152^{\circ}$ – $153^{\circ}$  at 755 mm., and its phenylurethane, m. p.  $65^{\circ}$ – $66^{\circ}$ . When oxidised, the alcohol yields small quantities of  $\alpha\alpha$ -dimethylbutaldehyde, b. p.  $102^{\circ}$ – $104^{\circ}$ , and of  $\alpha\alpha$ -dimethylacrylic acid, b. p.  $186^{\circ}$ – $187^{\circ}$ /755 mm., m. p.  $-13^{\circ}$ .  $\alpha$ -Bromo- $\beta$ -dimethylbutane, b. p.  $83^{\circ}$ – $85^{\circ}$ /145 mm.,  $d_4^{20}$  1.1958, prepared by treating the alcohol in a sealed tube at  $100^{\circ}$  with hydrogen bromide, undergoes isomeric change, which may occur in the following ways:

In order to decide which of these is produced,  $\gamma$ -bromo- $\gamma$ -methylpentane, b. p.  $82^{\circ}$ – $83^{\circ}$ /145 mm.,  $d_4^{20}$  1.2066,  $R_d = 37.67$ , is synthesised by the action of hydrogen bromide on the product of the interaction of magnesium ethyl bromide with ethyl acetate. The other,  $\beta$ -bromo- $\beta$ -methylpentane, b. p.  $77^{\circ}$ – $78^{\circ}$ /145 mm.,  $d_4^{20}$  1.1807,  $R_d = 37.67$ , is obtained in a similar way from the product of the interaction between magnesium propyl bromide and acetone. It is hence concluded that the action of hydrogen bromide on the alcohol is to produce  $\gamma$ -bromo- $\gamma$ -methylpentane. Alcoholic alkali hydroxide acts on it, to produce a mixture of hexenes as follows:  $\text{CH}_2\text{Me.CMe.CHMe.CH}_2\text{Me.CMeBr.CH}_2\text{Me} \rightarrow \text{CH}_2\text{Me.C(CH}_3)_2\text{.CH}_2\text{Me.}$

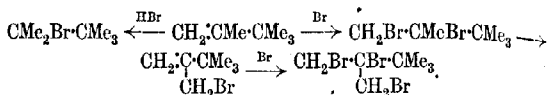

The first of these is the main product,  $\gamma$ -methylpentene being present only in very small quantity.

[With N. SHIBAEV.]— $\alpha\delta$ -Dibromo- $\beta\beta\delta$ -trimethylpentane, under the influence of diethylamine, is transformed into diisobutenyl in the following way:

With EUGÉNIE OPEL.]— $\beta\gamma\gamma$ -Trimethyl- $\Delta^4$ -butene, b. p.  $75^{\circ}$ – $80^{\circ}$ , prepared from  $\beta$ -hydroxy- $\beta\gamma\gamma$ -trimethylbutane by distillation through 50% sulphuric acid. When oxidised, it yields  $\beta\gamma\gamma$ -trimethyl- $\alpha\omega$ -diol, m. p.  $91^{\circ}$ – $92^{\circ}$ , which on further oxidation yields hydroxy- $\alpha\beta\beta$ -trimethylbutyric acid, m. p.  $104^{\circ}$ – $106^{\circ}$ , and finally dimethylpropionic acid and formic acid. The hydrocarbon, on oxidation in ethereal solution, gives a dibromide,  $\text{C}_7\text{H}_{14}\text{Br}_2$ , m. p.  $38^{\circ}$ – $39^{\circ}$ , from which it is regenerated on distillation from potassium dust. Bromination in acetic acid solution gives the bromide

of  $\beta$ -bromo- $\beta$ - $\gamma$ -trimethylbutane, m. p. 150—151°, which on hydrolysis yields the same alcohol, so that bromination does not appear to cause any structural change. Bromination in ethereal solution also produces small quantities of a tribromide,  $C_7H_{13}Br_3$ , m. p. 50.5—52°, and of saturated and unsaturated monobromides. The formation of these is explained by the following scheme:

The dibromide, when heated for eight hours at 160° in a sealed tube with sodium ethoxide, gives a mixture of a hydrocarbon and a mixture of ethers, b. p. 145—148°. The hydrocarbon on oxidation gives a mixture of  $\alpha$ -dimethylpropionic, formic, and  $\beta$ -dimethylbutyric acids, which points to it being  $\delta$ -dimethyl- $\Delta^4$ -pentadiene, b. p. 80—83°. This, when heated in a sealed tube at 100° with sodium, is converted into sodio- $\delta$ -dimethyl- $\Delta^4$ -pentene, which can be converted by the action of carbon dioxide into the sodium salt of  $\delta$ -dimethyl- $\Delta^4$ -pentene- $\alpha$ -carboxylic acid. The free acid has m. p. 48—49.5°. The ether, b. p. 145—148°, is a mixture of two isomeric ethers,  $CMe_3 \cdot CMe \cdot CH \cdot OEt$  and  $CMe_3 \cdot C(CH_2) \cdot CH_2 \cdot OEt$ , whilst the hydrocarbon is formed by an intramolecular rearrangement:  $CH_2 \cdot C(CH_2Br) \cdot CMe_3 \rightarrow CH_2 \cdot CBr \cdot CH_2 \cdot CMe_3 \rightarrow CH_2 \cdot C \cdot CH \cdot CMe_3$ .

[With SERGEI KAROLEV.]— $\beta$ - $\beta$ -Diphenylpropane- $\alpha$ -ol, b. p. 186—187°/15 mm.,  $d_4^{20}$  1.0968, is prepared by the reduction of  $\alpha$ -diphenylpropaldehyde; the urethane has m. p. 148—149°, and the acetate, b. p. 182—183°/14 mm. Dehydration with potassium sulphate caused intramolecular rearrangement, with the production of  $\alpha$ -diphenylpropylene,  $CH_3 \cdot CPh_2 \cdot CH_2 \cdot OH \rightarrow CH_3 \cdot Ph \cdot C \cdot CHPh$ .

R. T.

**Catalytic Dehydration of Alcohols by Dilute Sulphuric Acid.** J. B. SENDRENS (*Compt. rend.*, 1923, 176, 813—816).—The dehydration of alcohols by sulphuric acid does not consist in a simple absorption of water, but is a catalytic action, and the large proportion or high concentration of acid required for the dehydration of certain alcohols is only for the purpose of raising the temperature to an extent sufficient for the catalytic reaction to proceed, and, as would be expected from this reasoning, the same results are obtained with either concentrated or diluted sulphuric acid, provided the proportions of acid and alcohol employed are such as to produce a reaction mixture of the same boiling point in each case. With propyl alcohol, for example, a mixture of 100 c.c. of alcohol and 75 c.c. of concentrated sulphuric acid boils at about 140°, and gives propylene almost exclusively, whilst 40 c.c. of acid gives a mixture boiling at 125°, and a yield of 30% of propyl ether is obtained with the propylene. Propyl alcohol with 200% of the dihydrate,  $H_2SO_4 \cdot 2H_2O$ , also gives a mixture boiling at about 135°, with propylene as the chief product, and with 60% of

he dihydrate the b. p. is  $125^{\circ}$ , and 38% of propyl ether is produced. A reaction mixture boiling at  $125^{\circ}$  is also obtained with the hydrate,  $\text{H}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$ , mixed with a third of its volume of propyl alcohol, and the product consists of 40% of propyl ether, and a correspondingly diminished amount of propylene. Precisely analogous results were obtained with ethyl, isopropyl butyl, isobutyl, and isoamyl alcohols, the proportions of acid required to produce a certain result diminishing as the molecular weights and boiling points of the alcohols increase. Thus only a tenth of the quantity of  $\text{H}_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$  is required for the same volume of isoamyl alcohol as of propyl alcohol in order to produce the corresponding ether.

G. F. M.

**Preparation of Absolute Alcohol with Calcium Chloride and Lime.** WILLIAM A. NOYES (*J. Amer. Chem. Soc.*, 1923, 45, 37—862).—An apparatus is described by means of which alcohol of 99.0—99.5% concentration may be prepared rapidly by the use of calcium chloride. An apparatus is also described for preparing absolute alcohol with lime. When absolute alcohol is distilled from an excess of lime, a little calcium is carried over, probably as calcium ethoxide. Metallic sodium is not suitable for the preparation of absolute alcohol, because (1) sodium ethoxide, alcohol, water, and sodium hydroxide form an equilibrium such that some water will always pass over with the alcohol, (2) sodium ethoxide is very sensitive to oxidation on exposure to the air. On distilling a concentrated alcoholic solution containing equimolecular proportions of water and calcium chloride, alcohol of 99.5% concentration, or stronger, passes over; on concentration of such a solution, a solid alcoholate, not a hydrate, separates when the boiling point reaches  $95$ — $100^{\circ}$ , and there is an equilibrium between the alcoholate and the hydrate present.

W. S. N.

**The Preparation of Various Pinacones by the Action of Frignard Reagents on  $\alpha$ -Hydroxymethyl Ketones.** R. JOUQUIN and SUNG WOUSENG (*Compt. rend.*, 1923, 176, 682—84).—Pinacones of the general type,  $\text{OH}\cdot\text{CRR}'\cdot\text{CR}''\cdot\text{Me}\cdot\text{OH}$ , where  $\text{R}$ ,  $\text{R}'$ , and  $\text{R}''$  are alkyl groups, are obtained by the action of magnesium alkyl iodides on  $\alpha$ -hydroxyl methyl ketones of the general formula  $\text{OH}\cdot\text{CRR}'\cdot\text{CO}\cdot\text{CH}_3$ , the preparation of which has been previously described (this vol., i, 302). Thus the interaction of 3 mols. of magnesium ethyl iodide on methyl  $\alpha$ -hydroxy- $\alpha$ -ethyl-propyl ketone gave  $\beta$ -methyl- $\delta$ -ethylhexane- $\gamma\delta$ -diol,

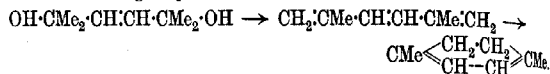

b. p.  $103$ — $104^{\circ}/11$  mm. From methyl  $\alpha$ -hydroxy- $\alpha$ -propylbutyl ketone and magnesium methyl iodide  $\beta$ -methyl- $\gamma$ -propylhexane- $\gamma\delta$ -diol,  $\text{OH}\cdot\text{CPr}_2\cdot\text{CMe}_2\cdot\text{OH}$ , b. p.  $110$ — $112^{\circ}/12$  mm., was obtained, whilst the same hydroxy-ketone and magnesium propyl iodide gave  $\alpha$ -methyl- $\epsilon$ -propyloctane- $\delta\epsilon$ -diol, b. p.  $137$ — $140^{\circ}/19$  mm. Magnesium methyl iodide and methyl  $\alpha$ -hydroxyl- $\alpha$ -tert.-butylethyl ketone gave  $\beta\gamma\delta$ -tetramethylpentane- $\gamma\delta$ -diol,  $\text{CMe}_3\cdot\text{CMe}(\text{OH})\cdot\text{CMe}_2\cdot\text{OH}$ , b. p.  $99$ — $100^{\circ}/13$  mm. All these pinacones are viscous liquids or low-melting solids. They have no characteristic odour, and do

not furnish crystalline hydrates with water. On dehydration by heating with dilute mineral acids, they are converted into pinacolines.  
G. F. M.

**Addition of Hydrogen to Acetylene Derivatives.** VIII. I. S. ZALKIND (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1830—1848).—When  $\beta$ -dimethylhexene- $\beta$ -diol is reduced with hydrogen by the Sabatier process, using a palladium catalyst, two stereoisomeric ethylenic reduction products may be obtained, namely, the *cis*- and *trans*-isomerides of  $\beta$ -dimethyl- $\Delta^7$ -hexene- $\beta$ -diol,  

$$\text{OH}\cdot\text{CMe}_2\cdot\text{CH}\cdot\text{CH}\cdot\text{CMe}_2\cdot\text{OH}.$$

One isomeride, the  $\alpha$ -form, melts at  $76\cdot5$ — $77^\circ$ , whilst the  $\beta$ -isomeride has m. p.  $69$ — $69\cdot5^\circ$ . The dehydration of these substances by sulphuric acid leads to the production of 2:3-dihydro-*p*-xylene in the following way:

The two isomerides are not interconvertible under the conditions of the catalytic reduction, but are formed side by side, the quantity of each isomeride in the reaction product being determined by the velocity with which the reduction is conducted. Thus if a large quantity of catalyst is used, the reduction proceeds rapidly to completion, giving as the main product the  $\alpha$ -isomeride, whilst a slow reduction produces principally the  $\beta$ -form. Both isomerides are converted by heat or by mild dehydrating agents into the  $\gamma$ -lactone, the  $\alpha$ -form suffering dehydration more readily. With phosphorus tribromide, they give an oily, unsaturated monobromide,  $\text{C}_8\text{H}_{13}\text{Br}$ . Bromination of the isomerides gives for each an oil and a crystalline compound, m. p.  $98\cdot5$ — $99\cdot5^\circ$ , both having the formula  $\text{C}_8\text{H}_{15}\text{O}_2\text{Br}_2$ . From the  $\alpha$ -isomeride, the main product is the oil, which is obtained as a by-product from the bromination of the second form. It is probable that some conversion of the stereoisomerides is effected in each case by the hydrogen bromide liberated during bromination.  
R. T.

**Existence of Alkyl Chlorites.** GIORGIO RENATO LEVI (*Gazzetta*, 1923, 53, i, 40—42).—Attempts to prepare alkyl chlorites from either silver chlorite and ethyl halide or barium chlorite and methyl sulphate have proved unsuccessful, an explosive reaction usually taking place (cf. A., 1922, i, 527; ii, 567).  
T. H. P.

**Phosphorous Acid Esters.** The Influence of the Character of the Groups  $\text{R}'$ ,  $\text{R}''$ ,  $\text{R}'''$  on the Stability of the Molecular Complexes  $\text{R}'\text{R}''\text{R}'''\text{C}\cdot\text{O}\cdot\text{PCl}_2$  and  $\text{R}'\text{R}''\text{R}'''\text{C}\cdot\text{O}\cdot\text{P}(\text{OH})_2$ . I. DAVID RUNCIMAN BOYD and GUY CHIGNELL (*T.*, 1923, 123, 813—817).

**The Action of Organomagnesium Salts on Sulphuryl Chloride; Preparation of Aliphatic Sulphonyl Chlorides and Bromides.** E. CHERBULEZ and O. SCHNAUDER (*Helv. Chim. Acta*, 1923, 6, 249—257).—By the action of aromatic or aliphatic

organomagnesium compounds on sulphuryl chloride, sulphonyl chlorides or bromides can be obtained, provided that the solution of the Grignard compound is added to the sulphuryl chloride, the latter being present in excess throughout the reaction. In the aromatic series, the yields are poor, but in the aliphatic series they are from 25% to 35% of theory. The yields are lower at very low temperatures,  $-20^{\circ}$  to  $-40^{\circ}$ , at which the product is chiefly halogenated hydrocarbon, than at higher temperatures; the best yields of aliphatic sulphonyl compounds are obtained at  $+10^{\circ}$ . Magnesium benzyl chloride behaves as an aliphatic compound. The magnesium alkyl chlorides and iodides with sulphuryl chloride both give sulphonyl chlorides, but the magnesium alkyl bromides give sulphonyl bromides, which are new. *Methanesulphonyl bromide*, obtained in 21% yield from methyl bromide, is a colourless liquid with a pungent odour, b. p.  $72-73^{\circ}/15$  mm., or  $173^{\circ}$  (decomp.) at the ordinary pressure. *Ethanesulphonyl bromide* (35% yield), from ethyl bromide, a colourless liquid with a pungent odour, has b. p.  $80^{\circ}$  at 13 mm., or  $170^{\circ}$  with rapid decomposition at the ordinary pressure.

The course of this reaction can be best explained by Meisenheimer and Casper's theory of the constitution of organomagnesium compounds (A., 1921, i, 654), in which it is assumed that they are co-ordination compounds. Assuming the co-ordination number of magnesium to be 6, the intermediate compound

may be formed. In favour of the formation of such an intermediate compound is the observation that, at low temperatures, when an iodide is used, the precipitation of the salt  $\text{MgCl}_2$  takes place very slowly. Such an intermediate compound would explain the formation of  $\text{R}\cdot\text{SO}_2\text{Cl}$  or  $\text{R}\cdot\text{SO}_2\text{Hal}$ , according to the nature of the halogen. When this is bromine, in the aliphatic series  $\text{R}\cdot\text{SO}_2\text{Br}$  is formed exclusively, but in the aromatic series a mixture of  $\text{R}\cdot\text{SO}_2\text{Br}$  and  $\text{R}\cdot\text{SO}_2\text{Cl}$  is obtained. At very low temperatures, a mixture of  $\text{R}\cdot\text{Br}$  and  $\text{R}\cdot\text{Cl}$  is formed. The formation of sulphinic acid and sulphone by the action of an organomagnesium compound on a sulphonyl chloride can be explained by the same hypothesis.

In the course of the reaction between organomagnesium bromides or iodides and sulphuryl chloride, free bromine or iodine is always formed, the proportion increasing at higher temperatures.

E. H. R.

**Hydration of Acetic and Hydrochloric Acids and the Factors Determining the Activity of the Hydrogen-ion.** W. C. McC. LEWIS, DORIS E. MERRIMAN, and T. MORAN (*J. Amer. Chem. Soc.*, 1923, 45, 702-712).—The activity of the hydrogen-ion (produced from acetic acid) in the presence of various amounts of sucrose has been experimentally determined at  $30^{\circ}$ . In the case of acetic acid, the activity of the hydrogen-ion can be completely accounted for by assuming acetic acid to be hydrated to the extent of three molecules of water for each molecule of acid,

and then identifying activity with the concentration of the hydrogen-ion per unit of free water space in the sucrose solution. The change in the activity of the hydrogen-ion (produced from hydrochloric acid) in the presence of sucrose cannot be accounted for by a space correction alone. In this case, the heat of dilution of the ion must be considered, and it is shown that by combining the two above factors it is possible to account for 80–90% of the observed activity; no definite conclusion is drawn as to the causes of the excess activity observed. It is pointed out, however, that the excess might be attributed to an increased ionisation of the acid, a modification of a suggestion originally made by Scatchard (A., 1922, i, 230). The average degree of hydration of hydrogen chloride in solution between 0.1N and 1.2N has been calculated by an examination of the kinetics of the inversion of sucrose by this acid, employing the data of Fales and Morrell (A., 1922, ii, 832). It is shown to be approximately 7. J. F. S.

**Electrolysis of Acetic Acid with Commutated Direct Current.** EMIL BAUR (*Z. Elektrochem.*, 1923, 29, 105–110).—Solutions of acetic acid of various concentrations and also solutions of potassium acetate in acetic acid have been electrolysed between bright platinum electrodes by means of commutated direct current. The products of electrolysis consist of carbon dioxide and hydrocarbons, the latter consisting of approximately equal volumes of ethane and methane. The results are discussed in connexion with the author's hypothesis of the optically sensitised photolysis.

J. F. S.

**Separation of Methyl Oleate and Linoleate by Fractional Distillation.** ÉMILE ANDRÉ (*Compt. rend.*, 1923, 176, 686–689).—The separation by fractional distillation under pressures of 1–3 mm. of mixtures of methyl oleate and linoleate was attempted, but the polymerisation which occurred during the long series of repeated distillations that was necessary proved a serious obstacle against the isolation of the higher boiling methyl linoleate in a pure condition. The highest iodine value obtained was 160, as compared with 172.7 for the pure ester. A certain quantity of fairly pure methyl oleate was, however, obtained having an iodine value of 92–95, by uniting the fractions with the lowest iodine values and redistilling. It is suggested that the addition of a small quantity of a phenolic substance (antioxygen) to the esters might facilitate the separation.

G. F. M.

**The Course of the Reaction in the Acetoacetic Ester Synthesis.** K. H. MEYER (*Z. angew. Chem.*, 1923, 36, 169).—Scheibler's view (*ibid.*, 6; cf. also this vol., i, 82) that, in the above synthesis, ethyl sodioacetate is first formed and reacts with a second molecule of ethyl acetate to give a salt-like condensation product, which is then decomposed by acids into alcohol and ethyl acetoacetate, was put forward by the author ten years ago (*Annalen*, 1913, 398, 49). Whilst in the latter case the explanation was based on analogy with ethyl sodiomalonate, Scheibler's work appears to afford experimental proof of it.

W. T. K. B.

**Action of the Grignard Reagent on Keto-acids.** PHILIP K. PORTER (*J. Amer. Chem. Soc.*, 1923, 45, 1086—1087).—Lævulic acid reacts in ethereal solution with magnesium methyl iodide to give isohexolactone, and with magnesium ethyl bromide to give the lactone of  $\gamma$ -hydroxy- $\gamma$ -methylhexoic acid, the yields being 31.5% and 35.1%, respectively. The yields of these compounds previously obtained, starting from ethyl lævulate, are 30—35% (Noyes and Marvel, A., 1917, i, 455) and 35% (Grignard and Moissan, A., 1903, i, 31), respectively. W. S. N.

**The Hydroxy-acids Contained in an Oil from Grape Stones.** ÉMILE ANDRÉ (*Compt. rend.*, 1923, 176, 843—845).—The hydroxy-acids, the presence of which in oil of grape stones has previously been established (*ibid.*, 1921, 172, 1296), were isolated from the other fatty acids which accompanied them by taking advantage of the partial insolubility of the hydroxy-acids in light petroleum when a relatively high proportion is present in the fatty acid mixture, and, secondly, of the greater solubility of the lithium salts of the hydroxy-acids, which results in their accumulating in the mother-liquors from the crystallisation of the lithium soap. By repeated alternate application of these two principles, 15—16% of the original material was separated as a viscous liquid, having saponification value 222, iodine value 69.2, and average molecular weight 252.2. It is concluded that the acetyl value of the oil of grape stones cannot therefore be attributed to ricinoleic acid, but rather to hydroxy-acids of lower molecular weight containing  $C_{14}$  to  $C_{16}$ . There would appear to be at least two such hydroxy-acids, one saturated, and the other having an ethylenic linking.

G. F. M.

**Synthesis of an Acid of the Digitoxonic Acid Group.** GÉZA ZEMPLEN (*Ber.*, 1923, 56, [B], 686—689).—An acid which closely resembles natural digitoxonic acid in structure and properties has been obtained by the condensation of crotonaldehyde with ethyl bromoacetate and oxidation of the product with perbenzoic acid.

*Ethyl  $\beta$ -hydroxy- $\Delta^1$ -hexenoate*,  $CHMe:CH-CH(OH):CH_2 \cdot CO_2Et$ , b. p.  $86^\circ/0.5$  mm., is prepared by the addition of activated zinc to a well-cooled mixture of crotonaldehyde and ethyl bromoacetate. The success of the operation (which is fully described in the original) appears to be greatly dependent on details; replacement of zinc by magnesium leads to less satisfactory results. The ester is oxidised by perbenzoic acid in chloroform solution, and the product converted by barium hydroxide into *barium  $\beta,\delta$ -trihydroxy- $n$ -hexoate*, which could not be caused to crystallise. The corresponding free acid does not exhibit any tendency towards crystallisation; it yields a *hydrazide*,  $C_{12}H_{18}O_4N_2$ , coarse, colourless crystals, m. p.  $159^\circ$ . H. W.

**Preparation of Oxalic Acid from Acetylene.** M. LUCRETIA KEARNS, L. HEISER, and J. A. NIEUWLAND (*J. Amer. Chem. Soc.*, 1923, 45, 795—799).—Oxalic acid can be prepared by passing

acetylene into dilute nitric acid (75% by volume), with mercuric nitrate as catalyst. An acetylene-mercury compound is first formed, which gives acetaldehyde with part of the nitric acid; the aldehyde is then oxidised to oxalic acid by the nitric acid. Oxalic acid is also formed by the action of (1) nitrogen oxides on acetylene, (2) nitrogen oxides on acetaldehyde, (3) acetaldehyde vapour on nitric acid.

Acetaldehyde can be obtained by passing (1) acetylene over dry mercuric nitrate, (2) nitrogen oxides over metallic mercury, and then passing acetylene over the resulting salt. The mercury salt may be regenerated, after reduction, by means of nitrogen oxides.

W. S. N.

**The Decomposition of the Peroxides of Succinic, Fumaric, and Benzoic Acids by Heat and their Relation to the Behaviour of the Corresponding Salts on Electrolysis.** FR. FICHTER and ALBERT FRITSCH (*Helv. Chim. Acta*, 1923, 6, 329-336).—In a previous paper (A., 1918, i, 369), it was suggested that in the Kolbe hydrocarbon synthesis by the electrolysis of salts of organic acids, unstable peroxides are formed intermediately and are decomposed by the relatively high temperature of the anode, forming the hydrocarbon. Confirmation of the theory is obtained from a study of the decomposition of peroxides of succinic, fumaric, and benzoic acids. Succinyl peroxide (purity about 86%) decomposes explosively when heated in a bomb, forming a mixture of gases containing 55.2% of carbon dioxide and 21.1% of ethylene, the volume ratio being 2.6:1 instead of the theoretical 2:1. Gentler decomposition by heating in boiling xylene gave a ratio 2.25:1. Electrolysis of succinates gave a very similar ratio, 2.4:1. Fumaroyl peroxide could only be obtained in a very impure form by the action of sodium peroxide on fumaroyl chloride in ice-water. When decomposed in the bomb it gave 67.6% of the expected yield of carbon dioxide and 10.6% of acetylene. Electrolysis of sodium fumarate gave 19.9% of the theoretical yield of acetylene. Benzoyl peroxide decomposed explosively when heated in a bomb at 180–200°, giving 80.2% of the theoretical yield of carbon dioxide and 39.1% of diphenyl. By the electrolysis of benzoates, no diphenyl is produced, because the oxidation potential needed for peroxide formation is higher than the nucleus can carry without itself being oxidised (cf. Fichter and Krummenacher, *loc. cit.*).

E. H. R.

**Ketens. XLVI. Attempts to Prepare Diketens.** H. STAUDINGER and W. KREIS (*Helv. Chim. Acta*, 1923, 6, 321-326).—It was hoped to prepare the diketene  $\text{OC}(\text{CH}_3)_2\text{CH}_2\text{CO}$  from ethanetetra-carboxylic dianhydride. This anhydride can be obtained by treating ethanetetra-carboxylic acid with an ethereal solution of oxalyl chloride, or by the action of oxalyl chloride on the silver salt, as well as by the method of Philippi and Hanusch (A., 1920, i, 594). When heated under reduced pressure, the anhydride gives no trace of ketene; with aniline, it gives a diamide which, when heated, decomposes into carbon dioxide and succin-

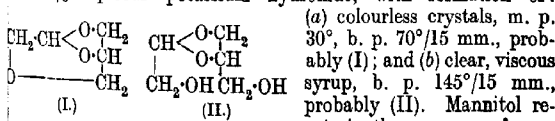

anilide. When ethylenetetracarboxylic acid is boiled for several days, a new acid is formed, which appears to be *ethylenetricarboxylic acid*, m. p. 180—184°.

With oxalyl chloride, the tetracarboxylic acid or its silver salt decomposes, forming a brown, amorphous compound, which appears to be a polymerised form of a new *carbon suboxide*, CO·C·C·CO. A similar brown, amorphous substance is formed, together with diphenylacetic anhydride, by the action of diphenylketen on ethylenetetracarboxylic acid. *Dimethyldicarboxyglutaric dianhydride* (annexed formula) was obtained by the action of diphenylketen in ethereal solution on dimethyldicarboxyglutaric acid. It forms colourless crystals, m. p. 126—127°. When heated, the anhydride decomposes without formation of any trace of diketene.

E. H. R.

**Cellulose Chemistry. III. Bromoparacetaldehyde and Monobromoacetaldehyde. Preparation, Properties, and Utilisation for the Synthesis of Bromo- and Hydroxy-cyclic Acetals related to Polysaccharides.** HAROLD HIBBERT and HAROLD SANFORD HILL (*J. Amer. Chem. Soc.*, 1923, 45, 734—751).—Bromoparacetaldehyde (cf. Helferich and Speidel, A., 1922, i, 6), which is prepared by the addition of bromine to cold paracetaldehyde in the presence of sunlight, breaks down on slow distillation into bromoacetaldehyde (*semicarbazone*, long, flat needles, m. p. 128°, lecomp.), the polymerisation of which to the trimolecular compound occurs spontaneously, more rapidly in the presence of concentrated acids. The bromo-aldehyde has been used to prepare cyclic acetals, the essential structure of which is present in maltose, cellobiose, levoglucosan, diamylose, and the cellulose unit.

The cold, crude product of bromination of paracetaldehyde reacts with  $\alpha$ -bromohydrin, with formation of *bromoethylidene bromohydrin*, a heavy oil, b. p. 118—120°/10 mm., yield 56%, and with ethylene glycol with formation of *bromoethylidene glycol*, a heavy oil, b. p. 63—65°/12 mm.; the latter is also obtained in 12% yield when ethylene glycol is heated at 100° with a little sulphuric acid and the "crude syrup," obtained by extracting the crude bromination mixture by means of ether. Under similar conditions, trimethylene glycol reacts with the "crude syrup," yielding *bromoethylidene trimethylene ether*, b. p. 80—86°/12 mm. Similarly, glycerol, "crude syrup," and sulphuric acid give *bromoethylidene glycerol*, b. p. 137—140°/15 mm., alternative formulæ of which are suggested; this compound is decomposed by means of 3·5% aqueous potassium hydroxide, with formation of:

concentrated hydrochloric acid with cold, freshly distilled bromo-

acetaldehyde to give *di(bromoethylidene)-mannitol*,

slender, white needles, m. p. 137–141°, but this is not produced from either the extracted syrup or the crude bromination mixture. It is shown that acetaldehyde and  $\alpha$ -bromohydrin react in the presence of a trace of iodine to give *ethylidene bromohydrin*, a colourless oil, b. p. 168–169°.

W. S. N.

**The Preparation of Mesityl Oxide.** RENÉ LOCQUIN (*Ann. Chim.*, 1923, [ix], 19, 32–44).—A general survey of various methods shows that they may be grouped in two series, (a) those in which condensation and dehydration of two molecules of acetone are effected simultaneously, (b) those in which diacetone alcohol [*isohexane- $\beta$ -one- $\delta$ -ol*] is obtained as an intermediate. The author considers that a simple standard method is required, and gives details of one based on condensation under the influence of sodium hydroxide solution and subsequent dehydration by means of oxalic acid. Only 20% of the acetone reacts, and from this portion a 75% yield is obtained; the remainder may be recovered unchanged.

H. J. E.

#### Some Constitutional Problems of Carbohydrate Chemistry.

JAMES COLQUHOUN IRVINE (T., 1923, 123, 898–921).—A lecture delivered before the Chemical Society on February 22nd, 1923.

#### The Influence of some Normal Salts on the Mutarotation and Specific Rotation of Dextrose.

HANS MÜRSCHHAUSER (*Biochem. Z.*, 1923, 136, 66–70).—The velocity constants of the mutarotation of dextrose have been determined in the presence of a number of simple inorganic salts of the alkali and alkaline-earth metals and a few acetates in *N*-, 2*N*-, and 4*N*-concentrations of the salts. Of those examined, potassium chloride and bromide, like sodium chloride, retard the mutarotation, but hydrolysed salts of acetic acid accelerate it. The final value of the rotation of dextrose is influenced by the presence of salts, and twenty values are recorded ranging between  $[\alpha]_D +47.4$  and 61.2, the former for 4*N*-potassium iodide and the latter for 4*N*-calcium chloride.

H. K.

#### Physico-chemical Studies on Biological Reactions. III.

**Mutarotation of Sugars.** PAUL HIRSCH and ANNA ELISABETH KOSSUTH (*Fermentforsch.*, 1922, 6, 302–339).—The use of Löw's interferometer to follow the course of the mutarotation of dextrose and lactose shows that the refractive indices of solutions of these sugars prepared from the  $\alpha$ -modifications undergo slight increase in the refractive index, whilst those of solutions of the  $\beta$ -modifications show slight decrease, during the period of mutarotation (cf. Schmoeget, A., 1892, 948; Stolle, A., 1901, i, 368, 507; Trey, A., 1904, i, 292; Rabe, A., 1911, i, 14). These results throw doubt on Hudson's theory, that mutarotation of the sugars is due to hydration or dehydration.

Gradual increase in refractive index occurs also during the conversion of succinic anhydride into the acid, and during the

resolution of trimeric formaldehyde into simple molecules in aqueous solution; the results obtained in the latter case support Auerbach and Barschall's view that this resolution is accompanied by hydration (A., 1905, i, 859; 1908, i, 131). T. H. P.

**Fluoroacetyl Derivatives of Sugars.** I. D. H. BRAUNS (*J. Amer. Chem. Soc.*, 1923, 45, 833—835).—*Fluorotetra-acetylglucose*, m. p. 108°, *fluorohepta-acetylcellulose*, m. p. 187°, and *fluoro-riacetylxylose*, m. p. 87°, are prepared by the action of liquid hydrogen fluoride on the relevant acetyl sugar. The latter is placed in the receiver attached to a retort in which potassium hydrogen fluoride is heated. The operation takes thirty minutes. The methods of analysis are given. W. S. N.

**Dextrose and Sucrose Monosulphates.** V. T. SODA (*Biochem. Z.*, 1923, 135, 621—628; cf. A., 1922, i, 986).—By the action of chlorosulphonic acid in chloroform at  $-10^{\circ}$  on dextrose (18% excess) in dry pyridine, dextrose monosulphate is formed, and can be isolated without the intervention of the acetyl derivative. The solvents are removed, and the aqueous solution of the syrup suitably treated with lead oxide, barium carbonate, and silver sulphate to remove chlorides and sulphates. The crude barium salt is precipitated by alcohol. The pure brucine salt, crystallised from acetone, has m. p. 183° and  $[\alpha]_D^{25} -5.6$  (final value). The barium salt crystallises with  $2C_2H_5O$ ; the anhydrous salt has  $[\alpha]_D^{25} +32^{\circ}$ . In a similar manner, sucrose gives *barium sucrose monosulphate dihydrate*. The alcohol-free salt has  $[\alpha]_D^{25} +37.6^{\circ}$ . H. K.

**Mannose from White Spruce Cellulose.** E. C. SHERRARD and G. W. BLANCO (*J. Amer. Chem. Soc.*, 1923, 45, [4], 1008—1013).—Extraction of spruce wood flour by means of 2.8% sodium hydroxide solution gives no mannose, but the latter is formed when the alkali-extracted wood is hydrolysed by means of 5% hydrochloric acid. Moreover, an equal or even greater amount of dextrose is simultaneously produced, the total sugars formed being approximately equivalent to the cellulose removed. By the solution of cellulose in zinc chloride-hydrochloric acid solution or in Schweizer's reagent and reprecipitation, different amounts of mannose are removed. It is concluded that the mannose is not present as a mannan, and that either (1) if the mannose is not in true combination with the cellulose neither is part of the dextrose, or (2) both mannose and dextrose are loosely attached to the cellulose nucleus and hydrolyse with equal readiness. The latter alternative is probable, since mannose is found to be distributed in the  $\alpha$ -,  $\beta$ -, and  $\gamma$ -portions of the cellulose. W. S. N.

**Attempts to Prepare Isomeric Osazones. Dimorphism of Two Hydrates of Galactose.** OLOF SVANBERG (*Arkiv Kem. Min. Geol.*, 1922, 8, No. 25, 1—19).—Attempts to obtain a third ( $\gamma$ ) form of glucosazone and of glucosephenylmethylhydrazone were unsuccessful. Glucosephenylmethylhydrazone is converted by phenylhydrazine into glucosazone. All the specimens of glucosazone obtained, from whatever source, melted at about 204—206°.

(decomp.), and had initial  $[\alpha]_D -104 \pm 2^\circ$  in pyridine solution, showing weak mutarotation. Glucose- $\alpha$ -phenylhydrazone melts at about  $148^\circ$ , and has initial  $[\alpha]_D -87^\circ$  and final  $[\alpha]_D -53^\circ$  in aqueous pyridine. Its mutarotation was studied between  $p_H$  4.9 and 13.8, and was found to be accelerated both by alkalis and by acids. The m. p. of glucose- $\beta$ -phenylhydrazone was found to be  $115-116^\circ$ , a lower value than that given by Behrend (A., 1907, i, 481). The mutarotation of this substance is accelerated by acids and retarded by alkalis. In weak acid, the negative rotation increases very rapidly at first, then passing through the equilibrium values given by the  $\alpha$ -compound; the equilibrium solution probably contains the  $\gamma$ -form in addition.

Galactosephenylmethylhydrazone is converted by phenylhydrazine in pyridine-acetic acid solution into galactose-phenylhydrazone, the latter, in dilute acetic acid solution, being rapidly converted by phenylmethylhydrazone into the phenylmethylhydrazone. Galactosazone has initial  $[\alpha]_D +121 \pm 2^\circ$  in pyridine solution. Galactose-phenylhydrazone and -phenylmethylhydrazone (cf. Votoček, A., 1921, i, 544) both exhibit dimorphism, which (at any rate, in the former case) cannot be correlated with constitutional differences. The phenylhydrazone crystallises from hot solutions in leaflets, from cooler ones in needles, which change into leaflets on keeping. E. E. T.

**The Hydrolysis of Maltose by Extract of Malt.** L. MAQUENNE (*Compt. rend.*, 1923, 176, 804-806).—The reducing power of a preparation of malt extract to which maltose has been added increases in comparison with that of the malt alone up to a certain limit, which varies with the temperature. The maximum increase is attained at about  $50^\circ$ , whilst at  $60^\circ$  the increase is very small. These facts can be explained most naturally by the assumption that malt extract contains maltase in addition to amylase, and that the maltose is, by its action, partly hydrolysed to glucose. This observation will obviously throw doubt on the conclusions drawn from results obtained on the hydrolysis of starch by malt extract and based on the assumption that maltose was the sole product of hydrolysis (Maquenne and Roux, A., 1906, i, 327, 547; ii, 623). G. F. M.

**Carbohydrates. III. The Action of Phosphorus Pentachloride on Octa-acetylmaltose.** PERCY BRIGL and PAUL MISTELE (*Z. physiol. Chem.*, 1923, 126, 120-129).—Octa-acetylmaltose reacts with phosphorus pentachloride at  $104-105^\circ$  to form  $\alpha$ -chloro- $\beta$ (?)-trichloroacetylhexa-acetylmaltose, m. p.  $132-133^\circ$ ,  $[\alpha]_D^{25} +80.0^\circ$ , which forms white needles, soluble in benzene, chloroform, ethyl acetate, acetone, or hot alcohol. On hydrolysis with methyl-alcoholic ammonia, maltose is obtained, isolated as maltazone, decomp.  $206^\circ$ . This shows that the maltose grouping is still intact. W. O. K.

**Starch.** F. W. TIEBACKX (*Pharm. Weekblad*, 1923, 60, 338-339).—The phosphorus stated to be always present in starch is

probably contained in an ester group which is removed by gradual hydrolysis on keeping or warming; this explains the increase in conductivity and decrease in viscosity.  
S. I. L.

**Hydrolysis of Starch by the System : Neutral Salts + Amino-acids + Peptone.** HUGO HAEHN (*Biochem. Z.*, 1923, 135, 37—602).—A 1% solution of soluble starch was treated with various quantities of a mixture of *N*/10-solutions of sodium, potassium, and calcium chlorides, with the addition of alanine and eucine and albumose or Witte's peptone. After incubation for 1 day at 37°, the solutions were tested with iodine solution. In many cases, a disappearance of the blue starch iodide colour was observed and particularly with the mixture of salts, amino-acids, and peptone. The liquid reduced Fehling's solution. The author considers the experiments prove the chemical hydrolysis of starch without the intervention of living matter.  
H. K.

**Solvents of some Cellulose Esters.** ERNEST WALTER JOHN MARDLES (*J. Soc. Chem. Ind.*, 1923, 42, 127—136r).—The relative solvent power of single and mixed liquids for some cellulose acetates, nitrates, nitroacetates, and chloroacetates was determined by investigating the temperature at which precipitation occurred on cooling, or where this method failed by finding the amount of a non-solvent required to initiate precipitation. The solubility depends on the specific character of both the liquid and the cellulose ester; it has a high temperature coefficient, and many non-solvents may become solvents when suitably mixed with other solvents, and *vice versa*. In general the solvent power and degree of dispersion of the cellulose esters are highest under conditions which admit of the greatest molecular attraction between the dispersed phase and the dispersing medium.  
G. F. M.

**Hydrolysis of Pectin.** FRANK TUTIN (*Biochem. J.*, 1923, 17, 83).—Theoretical. The author replies to various criticisms of his suggestion that pectin probably is the dimethylisopropenyl ester of pectic acid.  
S. S. Z.

**Lignin.** WALTHER SCHRAUTH (*Z. angew. Chem.*, 1923, 36, 149—152).—Based on observations made by previous workers on the degradation and reduction products and derivatives of lignin, the author develops a theory of the constitution of this substance, which attempts to reconcile the conflicting deductions which have from time to time been made. It is suggested that the fundamental unit of the lignin molecule is formed by the condensation of three molecules of 5-hydroxymethylfurfuraldehyde, which is itself produced by the internal condensation of carbohydrates. The unit so formed will consist of a compact condensed ring system, of which three of the outer rings are furan nuclei, and the other three outer rings and the central ring benzene nuclei. Hence under conditions favouring the fission of the furan rings, benzene derivatives appear as degradation products of lignin, and of the humic acids, etc., which with the efflux of time are developed from the

lignin during coal formation. The theory is further developed to account for the formation of methoxyl groups, ligninsulphonate acids, condensation products from the above fundamental unit and so forth.

G. F. M.

**Transport Experiments with Electrometric Ionisable Derivatives of Hydroxylamine.** WILLIAM A. NOYES and JAMES H. HIBBEN (*J. Amer. Chem. Soc.*, 1923, 45, 355—359).—Qualitative transport experiments have been carried out with aqueous solutions of trimethylamine oxide, hydroxytrimethylammonium salts, methoxytrimethylammonium iodide, ethoxytrimethylammonium bromide, trimethyliodomethylammonium hydroxide, and ethoxytrimethylammonium hydroxide. The solutions in many cases contained 7% of gelatin, and the cathode liquid contained hydrochloric acid. It has been shown that in each case an hydroxy-, a methoxy-, or an ethoxy-group remains with the nitrogen as a part of the kation. The linking of these groups to the nitrogen must therefore be very different from that of the hydroxyl or other atom or group which travels toward the anode during the electrolysis. The resistance of the solutions of trimethylamine oxide hydrate and of ethoxytrimethylammonium hydroxide seems more consistent with the hypothesis that the hydroxyl-ion of these compounds is attached to the nitrogen by a principal valency of such a character that it is only slightly ionised, than with that of the unlocalised polar valency assumed by Lewis and Langmuir (*A.*, 1920, ii, 243).

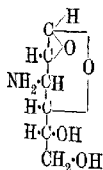

J. F. S.

**Constitution of the Ampholytes, particularly the Amino-acids, and their Dissociation Constants.** NIELS BJERRUM (*Z. physikal. Chem.*, 1923, 104, 147—173).—A discussion of the constitution of ampholytes in which it is shown that the aliphatic amino-acids in an undissociated condition are present almost completely (about 95%) as salt-like double ions  $^+\text{NH}_3\text{RCO}_2^-$ . They are therefore not true amino-acids, but rather ammonium salts. The presence of hydrogen- or hydroxyl-ions in their solutions does not indicate that they are acids, but that hydrolysis of the salt has taken place. The constants  $k_a$  and  $k_b$ , by which the acid and basic character of the amino-acids has hitherto been represented, are not dissociation constants, but rather hydrolysis constants. The real dissociation constants, which give the strength of the acid and base within the neutralised amino-acid molecule, are  $K_A = K_{\text{H}_2\text{O}} : k_b$  and  $K_B = K_{\text{H}_2\text{O}} : k_a$ , where  $K_{\text{H}_2\text{O}}$  is the dissociation constant of water. The values of  $K_A$  and  $K_B$  are such that they are in keeping with the demands of the structural formula. From the nature of the acid and basic groups the values of  $K_A$  and  $K_B$  may be deduced if the influence of the other substituents is taken account of in the usual manner. That the amino-acids contain no free amino-group is confirmed by many chemical reactions, and many physico-chemical properties are in keeping with a salt-like nature rather than with an acid character. This is seen particularly in the fact that they increase the solubility of other

salts, and that they are more soluble in salt solutions than in water. Amongst the aromatic amino-acids, there are also double ions of the form  $^+NH_3 \cdot R \cdot CO_2^-$  and true amino-acids,  $NH_2 \cdot R \cdot CO_2H$ , with free amino- and carboxyl-groups and this true acid may be present in amounts from 10% to 90%. In the case of the aromatic phenols, the double ion form is not present. From the dimensions of the dissociation constants of an ampholyte it is possible to deduce the ratio of the amounts of the two forms present. It is shown theoretically to be probable that for an ampholyte the product  $K_A \cdot K_B$  cannot be smaller than  $4K_{H_2O}$ , that is  $k_a \cdot k_b$  cannot be greater than  $\frac{1}{4}K_{H_2O}$ . From this it follows that the portions of an ampholyte present as anion and kation can never be more than 50%. A number of preliminary experiments confirming the above-mentioned results are recorded.

J. F. S.

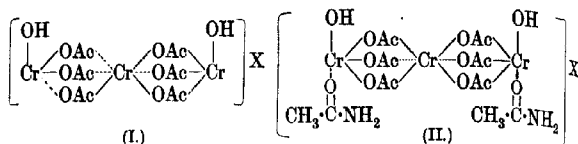

**Epiglucoamine.** P. A. LEVENE and G. M. MEYER (*J. Biol. Chem.*, 1923, 55, 221—227).—When triacetylmethylglucoside- $\beta$ -chlorohydrin (Fischer, Bergmann, and Schotte, A., 1920, i, 420) is heated with concentrated ammonia, methylepiglucoamine is obtained in the form of its acetate, m. p. 214° (corr.) after turning brown at 210°,  $[\alpha]_D^{20} -130^\circ$  in 2.5% hydrochloric acid. The corresponding hydrochloride, long needles, has  $[\alpha]_D^{20} -138^\circ$  in 2.5% hydrochloric acid. Methylepiglucoamine is readily hydrolysed by hydrochloric acid; the isolation of epiglucoamine has not, however, been accomplished owing to the ease with which this compound loses a molecule of water with the formation of *anhydro-epiglucoamine*, which has been isolated in the form of its hydrochloride,  $C_6H_{11}O_4N \cdot HCl$ , m. p. (decomp.) 216° (corr.) after changing colour at 190°,  $[\alpha]_D^{20} -172^\circ$  in 2.5% hydrochloric acid. That epiglucoamine is the first product of hydrolysis has been shown by the preparation from the reaction mixture of its phenylosazone,  $C_{18}H_{22}O_3N_5$ , long, lemon-yellow needles, m. p. 207° (corr.),  $[\alpha]_D^{20} -41^\circ$  (initial) in a solvent composed of four parts of pyridine and six parts of 50% (by volume) methyl alcohol. Anhydroepiglucoamine does not reduce Fehling's solution, but acquires this property on hydrolysis; on the basis of this behaviour, the annexed structure has been assigned to it. That the amino-group is in the  $\gamma$ -position both in this compound and in epiglucoamine follows from the preparation of the osazone of the latter (see above), which excludes the alternative  $\beta$ -position. The space arrangement of this group is, however, quite arbitrary. The configuration of epiglucoamine evidently depends on that of the  $\beta$ - and  $\gamma$ -carbon atoms.

E. S.

**The Addition of Acid Amides to Ferric and Chromic Acetates.** R. WEINLAND and HEINZ HACHENBURG (*Z. anorg. Chem.*, 1923, 126, 285—304).—Compounds formed from ferric or chromic chlorides by the addition of sodium acetate and weakly

basic acid amides are described and formulae suggested. The general type of the parent compound is shown by (I).

The central chromium atom is the only one exercising its full co-ordination number of 6: the others are co-ordinatively unsaturated and can presumably unite with one, two, or three molecules of an amide to give compounds of which II is typical. The compounds form coloured crystalline powders, brick red in the case of iron, and dark green in the case of chromium. The iron salts are easily soluble in cold water to garnet-red solutions, which are, however, unstable, so that recrystallisation from water is impossible. They are less soluble in alcohol, but decompose in this solvent on long heating. Addition of pyridine to the alcoholic solutions results in the formation of salts with complex kations containing pyridine and four iron atoms, but no amide.

The chromium salts are more stable than those of iron; they are easily soluble in water, giving neutral solutions (in contrast to those of iron, which are weakly acid) which are quite stable, even when boiled. They are less soluble in alcohol than the iron compounds, the solutions being more stable.

*Hexa-acetatodihydroxotricarbamidetriferrichloride,*

crystallises from an alcoholic solution of hexa-acetatodihydroxotri-ferrichloride and carbamide with  $2\text{H}_2\text{O}$ . The anhydrous salt is obtained by the addition of ether to the mother-liquor. The corresponding *perchlorate* crystallises in small tablets, the *nitrate* forms small, rhombic tablets, and the *chloroferrate* crystallises with  $\text{H}_2\text{O}$  in domed prisms.

*Hexa-acetatodihydroxoquatricarbamidetrichromidiacetate,*

crystallises in green tablets from an aqueous solution of carbamide and the calculated quantity of the diacetate of the hexa-acetatotrichromibase.

*Hexa-acetatodihydroxodicarbamidetrichromichloride,*

is prepared like the preceding compound, but using the chloride of the base; the corresponding *nitrate* crystallises with  $3\text{H}_2\text{O}$  in right-angled tablets.

*Hexa-acetatodihydroxosquicarbamidetrichromichloride,*

is obtained by the addition of the calculated quantity of carbamide to the preceding chloride.

*Hexa-acetatodihydroxotrihiocarbamidetrichromichloride,*

crystallises in well-defined prisms; the corresponding *nitrate* ( $2\text{H}_2\text{O}$ ) and *perchlorate* ( $2\text{H}_2\text{O}$ ) were prepared.

*Hexa-acetatodihydroxodiacetamidetrichromichloride*,  
 $[\text{Cr}_3(\text{OAc})_6(\text{OH})_2(\text{NH}_2\text{Ac})_2]\text{Cl}$ ,

crystallises from an aqueous solution of the hexa-acetatodihydroxotrichromichloride and acetamide in anhydrous crystals and is converted by addition of lithium nitrate into *hexa-acetatodihydroxomonoacetamidetrichrominitrate*. It crystallises with  $2\text{H}_2\text{O}$ ; the corresponding *perchlorate* crystallises with  $\text{H}_2\text{O}$  in prisms. H. H.

**Hydrolysis and Polymerisation of Cyanamide.** H. C. HETHERINGTON and J. M. BRAHAM (*J. Amer. Chem. Soc.*, 1923, 45, 824—829).—The behaviour of cyanamide in both acid and alkaline solution has been studied and the course of the reaction followed by determinations of both cyanamide and carbamide.

By the action of mineral or organic acids, or acid salts, cyanamide is hydrolysed to carbamide, without the formation of dicyanodiamide; the reaction is unimolecular, the velocity of hydrolysis increasing with increasing acid concentration within the limits studied. In alkaline solutions, cyanamide is hydrolysed to carbamide, as well as polymerised to dicyanodiamide, the reaction probably being due to the catalytic influence of the hydroxyl-ion.

Since the presence of acids does not bring about polymerisation, the latter cannot be explained on the equilibrium theory of Werner (T., 1915, 107, 715); the ionic theory suggested by Grube and Kruger (A., 1914, i, 152) is, however, quite satisfactory. W. S. N.

**$\beta$ -Hydroxyglutarodinitrile.** R. LESPIEAU (*Compt. rend.*, 1923, 176, 754—756).— *$\beta$ -Hydroxyglutarodinitrile*,

was obtained as a viscous liquid, b. p.  $202\text{--}203^\circ/11\text{ mm.}$ , by the action of saturated potassium cyanide solution on the chloronitrile,  $\text{CH}_2\text{Cl}\cdot\text{CH}(\text{OH})\cdot\text{CH}_2\cdot\text{CN}$ , at a temperature not exceeding  $70^\circ$ . It has  $d_{25}^{25} 1.808$  and  $n_D^{20} 1.4805$ . On saturating with hydrogen bromide, a crystalline mass, m. p.  $230^\circ$ , consisting of the *hydrobromide*,  $\text{CN}\cdot\text{CH}_2\cdot\text{CHBr}\cdot\text{CH}_2\cdot\text{CN}\cdot\text{HBr}$ , is formed, which when decomposed with potassium carbonate yields crystals of  *$\beta$ -bromoglutarodinitrile*, m. p.  $87\text{--}88^\circ$ . G. F. M.

**Hydrocyanic Acid. An Ammono-carbonous Acid, an Ammono-formaldehyde, and a Formic Anammonide.** EDWARD C. FRANKLIN (*J. Physical Chem.*, 1923, 27, 167—186).—A theoretical paper in which an attempt is made to show that hydrogen cyanide possesses simultaneously the properties of an ammonio-carbonous acid, of a formaldehyde of the ammonia system, and of a compound related to ammonia as the unknown formic anhydride is to water. That hydrogen cyanide is an *ammono-carbonous acid*,  $\text{H}\cdot\text{NC}$ , is supported by the following reactions: its formation when carbon is heated in ammonia or a mixture of nitrogen and hydrogen; the action of nitrogen in converting sodium cyanide in the presence of sodium into sodium cyanamide; the formation of sodium cyanamide from sodium cyanide and sodium azide; the formation of sodium dicyanamide by the action of

cyanogen on sodium cyanide; the action of sodamide on carbon, carbon monoxide, and carbon dioxide; the reduction of sodium cyanamide and dicyanimide to sodium cyanide; the oxidation of sodium cyanide to sodium cyanate; the ammonolysis of ethyl carbylamine to ethylamine and hydrocyanic acid; the oxidation of methylcarbylamine to methylcarbimide; and the reduction of hydrogen cyanide to methylamine. That hydrogen cyanide is an *ammono-formaldehyde* is supported by its polymerisation to form compounds of unknown constitution; its condensation to form aldol-like products; its formation of additive compounds with hydrogen sulphites, hydroxylamine, hydrazine, and phenylhydrazine, and by the fact that the relation between hydrogen cyanide and methylamine is the same as that of an aldehyde to an alcohol. That it is *formic anammonide* is shown by the fact that hydrogen cyanide bears an analogous relation to formamide, formamidine, and the formimido-esters, respectively, as acid anhydrides do to acids.

J. F. S.

**Magnesyamine.** I. GIUSEPPE ODDO and EMANUELE CALDERARO (*Gazzetta*, 1923, 53, i, 64–74).—To the compound obtained by treating an organo-magnesium compound, such as magnesium ethyl iodide, in ethereal solution with dry ammonia the authors give, in accordance with the nomenclature proposed by Oddo (A., 1912, i, 721), the name magnesyamine. This product, like Grignard compounds, contains a molecule of ether, its composition being expressed by  $\text{NH}_2\cdot\text{MgX}\cdot\text{Et}_2\text{O}$ . Magnesyamine may be regarded as analogous to sodamide, better termed sodamine, but, unlike the latter, is obtainable easily and with constant properties. In the action of ammonia on magnesium ethyl iodide, the ethane liberated corresponds with only one of the hydrogen atoms of the ammonia:  $\text{MgEtI} + \text{NH}_3 = \text{NH}_2\cdot\text{MgI} + \text{C}_2\text{H}_6$ . Like Grignard compounds, magnesyamine forms with pyridine an *additive* compound,  $\text{NH}_2\cdot\text{MgI}\cdot 2\text{C}_5\text{H}_5\text{N}$ .

Magnesyamine reacts with acid chlorides giving the corresponding amides, the three stages of the reaction with benzoyl chloride being:  $\text{NH}_2\cdot\text{MgI} + \text{Ph}\cdot\text{COCl} = \text{NH}_2\cdot\text{CPhCl}\cdot\text{OMgI}$ , the latter  $+ \text{NH}_2\cdot\text{MgI} = \text{MgClI} + \text{MgIO}\cdot\text{CPh}(\text{NH}_2)_2$ , and the latter  $+ \text{H}_2\text{O} = \text{MgI}\cdot\text{OH} + \text{NH}_3 + \text{NH}_2\text{Bz}$ . With ethyl benzoate, magnesyamine reacts, giving dibenzamide, together with a small proportion of benzamide:  $2\text{Ph}\cdot\text{CO}_2\text{Et} + \text{NH}_2\cdot\text{MgI} = \text{NBz}_2\cdot\text{MgI} + 2\text{EtOH}$  and  $\text{NBz}_2\cdot\text{MgI} + \text{H}_2\text{O} = \text{NHBz}_2 + \text{MgI}\cdot\text{OH}$ ; similarly, the reaction between potassamide and benzoyl chloride yields a mixture of benzamide and dibenzamide. Magnesyamine reacts readily with ethyl phthalate, giving phthalimide, and in ethereal solution unites easily with benzonitrile or nitrobenzene, which are regenerated when the products formed are treated with water.

With benzaldehyde, magnesyamine reacts in two ways, one of the reactions, which yields mainly hydrobenzamide, being analogous to that between aldehydes or ketones and Grignard compounds, and the other to that between sodamide and aromatic aldehydes: (I)  $\text{Ph}\cdot\text{CHO} + \text{NH}_2\cdot\text{MgI} = \text{NH}_2\cdot\text{CHPh}\cdot\text{OMgI}$ ;  $3\text{NH}_2\cdot\text{CHPh}\cdot\text{OMgI} =$

$\text{MgI}\cdot\text{OH} + \text{NH}_3 + \text{MgIO}\cdot\text{CHPh}\cdot\text{NH}\cdot\text{CHPh}\cdot\text{NH}\cdot\text{CHPh}\cdot\text{OMgI} \rightarrow$   
 $\text{OH}\cdot\text{CHPh}\cdot\text{NH}\cdot\text{CHPh}\cdot\text{NH}\cdot\text{CHPh}\cdot\text{OH} \rightarrow \text{CHPh}\cdot\text{N}\cdot\text{CHPh}\cdot\text{N}\cdot\text{CHPh}.$   
 (II)  $\text{Ph}\cdot\text{CHO} + \text{NH}_2\cdot\text{MgI} = 2\text{H} + \text{NHBz}\cdot\text{MgI} \rightarrow \text{Ph}\cdot\text{CO}_2\text{NH}_2 +$   
 $\text{MgI}\cdot\text{OH}.$  Magnesylamine and benzophenone yield an additive  
 compound, which gives benzophenone when treated with water.

With acetylacetone, magnesylamine reacts with great readiness, yielding 2:5-dimethylpyrrole:  $\text{CH}_2\text{Ac}\cdot\text{CH}_2\text{Ac} + 2\text{NH}_2\cdot\text{MgI} =$   
 $2[\text{CH}_2\cdot\text{CMe}(\text{NH}_2)\cdot\text{OMgI}] \rightarrow 2[\text{CH}_2\cdot\text{CMe}(\text{NH}_2)\cdot\text{OH}] \rightarrow \begin{matrix} \text{CH}\cdot\text{CMe} \\ \text{CH}\cdot\text{CMe} \end{matrix} > \text{NH}.$

An analogous reaction occurs when acetylacetone is heated in a sealed tube at  $150^\circ$  with a slight excess of alcoholic ammonia (Paal, A., 1885, 1206).

The compound formed from magnesylamine and nitrobenzene gives, with pyridine, a yellow precipitate, consisting of the additive compound,  $\text{MgI}\cdot\text{O}\cdot\text{NPh}(\text{NH}_2)\cdot\text{O}\cdot\text{C}_6\text{H}_4\text{N}.$  T. H. P.

**Action of Acetylene on Zinc Ethyl.** J. F. DURAND (*Compt. rend.*, 1923, 176, 992–993).—Zinc acetylide is formed according to the equation  $\text{C}_2\text{H}_2 + \text{ZnEt}_2 = \text{ZnC}_2 + 2\text{C}_2\text{H}_6$  when acetylene is passed into a solution of zinc ethyl in light petroleum. It is a white substance, decomposed by water with formation of zinc hydroxide, and giving with ammoniacal cuprous chloride a red precipitate of copper acetylide. It is unstable in air, and becomes yellow on warming, owing to the formation of zinc oxide. G. F. M.

**Preparation of Dialkyl Mercury Compounds from the Grignard Reagent. II. Relative Stability of the Carbon-Mercury Linking in Dialkyl Mercury Compounds.** C. S. MARVEL and H. O. CALVARY (*J. Amer. Chem. Soc.*, 1923, 45, 820–823; cf. A., 1922, i, 329).—The reaction between the Grignard reagent and mercury halides has been applied to the production of dialkyl mercury compounds containing secondary and tertiary alkyl groups. The action of heat and of acids indicates that the carbon-mercury linking in  $\text{CR}_2\text{—Hg}$  is less stable than that in  $\text{CHR}_2\text{—Hg}$ , and this in turn less stable than that in  $\text{CH}_2\text{R—Hg}$ . Mercury di-*sec*.-butyl reacts in alcoholic solution with aqueous hydrochloric acid to give *mercuric sec.-butyl chloride*, m. p.  $30.5^\circ$ , and with aqueous hydrobromic acid to give *mercuric sec.-butyl bromide*, m. p.  $39^\circ$ . The Grignard reagent from *sec*.-octyl bromide reacts with mercuric chloride in ethereal solution to give *mercury di-sec.-octyl*, yield 52%, which decomposes when heated, with formation of free mercury; when the above Grignard reagent is treated with mercuric bromide, *mercuric sec.-octyl bromide*, m. p.  $98^\circ$ , is produced. The action of mercuric bromide on the Grignard reagent from *tert*.-butyl bromide leads to *mercury di-tert.-butyl*, b. p.  $78\text{—}82^\circ/5\text{ mm.}$  with decomp.; if an excess of mercuric bromide is used, *mercuric tert.-butyl bromide*, m. p.  $106^\circ$ , decomp., is formed. Similarly, *mercury di-tert.-amyl*, b. p.  $80\text{—}84^\circ/5\text{ mm.}$ , decomp., and *mercuric tert.-amyl bromide*, m. p.  $82^\circ$ , have been obtained.

The indices of refraction of various liquid mercury dialkyl compounds are given.

It is noted that the order of stability towards concentrated

hydrochloric acid is (1) mercury di-*n*-butyl, (2) mercury di-*sec*-butyl, (3) mercury di-*tert*-butyl. Similarly, mercury di-*n*-propyl is more stable than mercury di-*isopropyl*. The same order of stability towards heat is noted.

W. S. N.

**The Problem of Substitution in the Benzene Nucleus and the Thomson-Lewis-Langmuir Theory of Co-valence.** RONALD FRASER and JAMES ERNEST HUMPHRIES (*Chem. News*, 1923, 126, 161—168).—An attempt is made to account for the directive influence of substituents already present in the benzene nucleus in terms of the Thomson-Lewis-Langmuir theory of co-valence. The development of the theory is based on three postulates: (1) the tendency of a disintegrated octet is towards further disruption; and of a nearly completed octet towards completion; (2) the tendency towards octet stability of an atom with nearly completed octet is greater than the tendency to octet instability of an atom with disruption only incipient; (3) the more nearly a group approaches octet stability, the greater the ease of replacement at that point. It is considered that there can be all grades of octet stability between that exhibited in truly polar compounds, where an atom surrounded by a complete octet can exist as a free ion, and that present in typically non-polar compounds. It is shown that an ortho-para-directive substituent, X, has the atom which is linked to the nucleus in a state approaching octet stability; hence the electrons are drawn into X, making the nuclear carbon atom, C<sup>1</sup>, to which it is linked, positive and the ortho- and para-carbon atoms, C<sup>2</sup> and C<sup>4</sup>, negative. A meta-directive substituent, Y, however, such as NO<sub>2</sub>, SO<sub>3</sub>H, etc., has the atom linked to the nucleus in a state of incipient octet disruption; it is therefore positive, C<sup>1</sup> becomes negative, and the meta-carbon atom, C<sup>3</sup>, is also negative, on the principle of induced alternate polarities. Since a negative carbon atom tends to deprive its attached hydrogen atom of its electron, it is evident that a hydrogen atom attached to a negative carbon atom is in a condition favourable for substitution. It follows that a positive substituent such as NO<sub>2</sub>, SO<sub>3</sub>H, etc., is meta-directive, and a negative substituent such as halogen is ortho-para-directive. The terms positive and negative here have the opposite significance to that which they generally carry. Benzene substituents arranged according to the Hollemann series follow a descending order of octet stability. It is shown that a group which favours substitution in the meta-position should favour replacement in the ortho-para-positions, as is well known to be the case. A labile group is one that tends to complete its octet, and is therefore attached to a positive carbon atom. The lability of such a group will be increased by a group such as NO<sub>2</sub> in the ortho- or para-position. The entering group should be of greater octet stability than the one replaced. The theory also explains the loosening effect of ortho-para-directing groups or substituents in the meta-position. On similar lines to the above, the effects of two and three substituents in the benzene ring on the position taken up by an additional substituent are considered. E. H. R.

**The Benzene Formula of Lely.** S. C. J. OLIVIER (*Chem. Weekblad*, 1923, 22, 143—144; J. D. VAN ROON (*ibid.*, 144); H. A. J. SCHOUTISSEN (*ibid.*, 145); H. G. DERX and P. H. HERMANS (*ibid.*, 145—147).—Polemical. Replies to Lely (this vol., i, 99).  
S. I. L.

**Reaction of Nitrosyl Chloride on Toluene.** E. V. LYNN and HELEN L. ARKLEY (*J. Amer. Chem. Soc.*, 1923, 45, [4], 1045—1047; cf. A., 1919, i, 245; 1922, i, 417).—Although nitrosyl chloride is unaffected by benzene, it reacts readily with toluene in the sunlight, giving crystals of benzaldoxime hydrochloride; phenyl-nitrosomethane is presumably the initial product, but is evidently very unstable, since no blue coloration is produced. W. S. N.

**Separation of Xylenes.** H. T. CLARKE and E. R. TAYLOR (*J. Amer. Chem. Soc.*, 1923, 45, 830—833).—The literature dealing with the preparation and separation of the xylenes is contradictory and misleading.

Fractional distillation, selective sulphonation, crystallisation of the sulphonic derivatives, and selective hydrolysis of xylenesulphonic acid all lead to a partial separation of the three xylenes, but none of these processes alone is entirely suitable for the isolation of *o*-xylene and *p*-xylene.

A satisfactory procedure is described in which the above processes are combined [cf. *J.S.C.I.*, 1923, 394A]. W. S. N.

**A New Synthesis of Cumene and *p*-Cymene.** L. BEET (*Compt. rend.*, 1923, 176, 840—842).—Cumene and *p*-cymene were obtained by the action of 1 mol. of magnesium phenyl bromide, and magnesium *p*-tolyl bromide, respectively, on an ethereal solution of 1 mol. of isopropyl sulphate, according to the scheme  $\text{PhMgBr} + \text{SO}_4(\text{CHMe}_2)_2 \rightarrow \text{CHMe}_2\text{Ph} + \text{MgBrSO}_4\cdot\text{CHMe}_2$ . The yield of cumene, b. p. 151—152°/720 mm., amounted to 10%, and approximately the same for *p*-cymene, b. p. 173—175°/720 mm. The substances were each identified by the preparation and isolation of the respective barium sulphonates. G. F. M.

**Primary Tar Oil.** R. WARRINGTON and E. MOEHRLE (*Brennstoff-Chem.*, 1923, 4, 81—84).—Oil from primary tar was freed from phenols and bases, and fractionated under reduced pressure. Unsaturated compounds were removed by dilute sulphuric acid, with which, as they were highly unsaturated, they readily combined. The percentage loss was noted, and the purified residue treated with cold concentrated sulphuric acid to separate aromatic compounds as sulphonic acids, which were afterwards decomposed by steam. The residue consisted of paraffins and naphthenes, which are very difficult to separate, but some success was achieved by the use of fuming nitric acid which attacked the latter. The following compounds were proved to be present in the oil: a homologue of indene,  $\psi$ -cumene, durene, naphthalene, 1-methylnaphthalene, 2-methylnaphthalene, 1:6-dimethylnaphthalene. Indications were obtained of the presence of decahydronaphthalene,

dodecahydrodiphenyl, perhydrofluorene, and perhydroacenaphthene. Comparisons are made with coke-oven tar oil. T. S. W.

**Nature of the Hydrocarbons Present in Primary Tar Light Oils.** F. SCHÜTZ (*Brenstoff-Chem.*, 1923, 4, 84).—Hydrocarbons are the chief constituents of primary tar light oil—the following series occurring with very few gaps in the homologues: Paraffins,  $C_nH_{2n+2}$ ; olefines,  $C_nH_{2n}$ ; diolefines,  $C_nH_{2n-2}$ ; cyclic diolefines,  $C_nH_{2n-4}$ ; aromatic hydrocarbons,  $C_nH_{2n-6}$ ; reduced aromatic hydrocarbons (naphthenes). The chief constituents of primary coal tar "benzine," the light oil fraction boiling up to  $150^\circ$ , are aromatic hydrocarbons, then come the olefines in much smaller amounts, whilst only very small quantities of paraffins and other hydrocarbons are present. In researches on "benzines" from other tars (Fischer and Gluud, A., 1919, i, 379), little or no benzene was found, pentane and hexane chiefly being isolated. The cause of the difference may lie in the origin of the coal, or more probably in the method of distillation employed.

T. S. W.

**Occurrence of Ketones and Aldehydes together with Sulphur Compounds in Primary Tar Light Oil.** F. SCHÜTZ (*Brenstoff-Chem.*, 1923, 4, 84; cf. *J. Soc. Chem. Ind.*, 1923, 175A).—The 30–75° fraction of the light oil from primary tar contains about 14% of acetone, corresponding with 0.5 to 1 kg. per ton of coal. Acetaldehyde, paracetaldehyde, acetonitrile, methyl mercaptan, dimethyl sulphide, and carbon disulphide are present in smaller amounts.

T. S. W.

**The Basic Properties of the Nitro-group.** ÉMILE CHERBULIEZ (*Helv. Chim. Acta*, 1923, 6, 281–286).—When an equimolecular mixture of nitrobenzene and sulphuric acid monohydrate is cooled to  $-10^\circ$  to  $-20^\circ$ , after some delay the liquid crystallises in very pale green needles, m. p.  $11^\circ$ , having the composition  $C_6H_5 \cdot NO_2 \cdot H_2SO_4$ . That the crystals are really those of a compound is shown by the fact that crystallisation of the equimolecular mixture cannot be induced by crystals of either nitrobenzene or of sulphuric acid, but is started at once by a crystal of the new compound. By water and by solvents not miscible with sulphuric acid, the compound is split into its constituents, but it can be crystallised by cooling from an ethereal solution. Further evidence that compounds are formed between nitro-derivatives of hydrocarbons and sulphuric acid is afforded by the observation that nitromethane, nitrobenzene, and the three nitrotoluenes when dissolved in sulphuric acid increase its electrical conductivity. This increase in the case of *p*-nitrotoluene, which has the greatest effect, is about half as great as the increase caused by the weakly basic 1:2:4-dinitroaniline. It is therefore considered that mononitro-derivatives of hydrocarbons are very weak bases forming salt-like compounds with strong acids. In the dinitro-derivatives, this basic character has disappeared, for the dinitrobenzenes diminish the conductivity of sulphuric acid. Perchloric acid

in 70% aqueous solution has a powerful solvent action on nitro-compounds, possibly due to the formation of a loose compound between the acid and the nitro-group. E. H. R.

**Preparation of Potassium and Sodium Arylsulphoniodo-amides.** ELWYN ROBERTS (T., 1923, 123, 849—853).

**Preparation of a New Chloroethyl Ester [ $\beta$ -Chloroethyl Toluene-*p*-sulphonate], and the Treatment of Phenols, Alcohols, and Amino-compounds therewith.** BRITISH DYE-STUFFS CORPORATION, LTD., WILLIAM HENRY PERKIN, and GEORGE ROGER CLEMO (Brit. Pat. 193618).— $\beta$ -Chloroethyl toluene-*p*-sulphonate is obtained in good yield as a colourless syrup by boiling toluene-*p*-sulphonyl chloride with ethylene chlorohydrin for three hours. It boils at 210°/21 mm., and condenses readily with phenols, aromatic alcohols, and amines to give ethers, substituted diamines, etc. Thus on heating with phenol in presence of sodium hydroxide  $\beta$ -chloroethyl phenyl ether,  $\text{OPh}\cdot\text{CH}_2\cdot\text{CH}_2\text{Cl}$ , a pleasant smelling oil, b. p. 217—220°, is obtained as the main product, together with diphenylethylene ether,  $\text{OPh}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{OPh}$ , in lesser amount. Similar  $\beta$ -chloroethyl ethers are obtained from the cresols and naphthols. The chloroethyl ethers react readily with amines, giving  $\beta$ -phenoxyethyl derivatives of these bases. Thus  $\beta$ -naphthyl- $\beta$ -chloroethyl ether gives with dimethylamine  $\beta$ -naphthyl- $\beta$ -dimethylaminoethyl ether, of which the hydrochloride, m. p. 185°, has a local anæsthetic action. Benzyl alcohol on treatment with  $\beta$ -chloroethyl toluene-*p*-sulphonate and sodium hydroxide gives benzyl  $\beta$ -chloroethyl ether, b. p. 95—110°/16 mm. This substance also reacts readily with amines, for example, from diethylamine benzyl  $\beta$ -diethylaminoethyl ether is obtained.  $\beta$ -Chloroethyl toluene-*p*-sulphonate reacts with amines in presence of sodium carbonate; on heating with aniline, for example, a mixture of diphenylethylenediamine, and diphenylpiperazine is obtained, whilst with methylaniline the main product is diphenyldimethylethylenediamine,  $\text{NMePh}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{NMePh}$ , and some methyl- $\beta$ -chloroethylaniline, b. p. 124°/10 mm., is obtained.  $\beta$ -Chloroethyl toluene-*p*-sulphonate also reacts with *m*-nitrophenols and with aminophenols, yielding chloroethyl ethers, but the amino-group must previously be protected by acetylation. *o*-Acetamidophenyl  $\beta$ -chloroethyl ether forms long prisms, m. p. 97—98°.

G. F. M.

**New Type of Synthesis. I. Reaction between Halogen-Alkyl Sulphonates and Organomagnesium Halides.** HENRY GILMAN and N. J. BEABER (*J. Amer. Chem. Soc.*, 1923, 45, 839—842).—A preliminary study has been made of the reaction between various organomagnesium halides and halogen-alkyl esters of toluene-*p*-sulphonic acid. In all cases the  $\text{MgX}$  group is replaced by the halogen-alkyl group (cf. Ferns and Lapworth, T., 1912, 101, 273).

The following compounds were obtained with  $\beta$ -chloroethyl-toluene-*p*-sulphonate:  $\beta$ -Chloroethylbenzene, yield 36%, from

bromobenzene;  $\gamma$ -chloropropylbenzene, 59%, from benzyl chloride;  $\beta$ -chloroethylphenylacetylene, 75%, from phenylacetylene, and  $\beta$ -chloroethyl benzoate, 5%, from the benzoate  $\text{PhCO}_2\text{MgBr}$ .  $\gamma$ -Chloropropylbenzene was obtained in 31% yield from bromobenzene and  $\gamma$ -chloropropyl toluene-*p*-sulphonate, b. p. 216–219°/17 mm.,  $d_4^{20}$  1.2674,  $n_D^{20}$  1.5230. W. S. N.

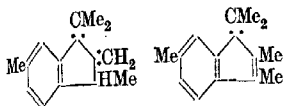

**Sodium Toluene-*p*-sulphochloramide ("Chloramine"), and Its Effect on certain Organic Substances.** N. O. ENGELDT (*Z. physiol. Chem.*, 1923, 126, 1–28).—The action of hypochlorite solutions on various organic substances has already been investigated by the author (cf. A., 1922, 1, 812), and similar experiments have now been carried out with "chloramine." Fats and carbohydrates are found not to react with "chloramine." Amino-acids react very similarly, qualitatively and quantitatively, as with hypochlorite. Hippuric acid, on the other hand, is not affected by the reagent, to which the  $-\text{CO}-\text{NH}-$  linking appears to be resistant. In accordance with this, proteins and peptones are much less affected by the reagent than by hypochlorite. Free ammonia and certain aldehydes also react with it to a much less extent. W. O. K.

**Syntheses in the Indene Series. IV.** A. P. ORÉKHOV [with V. SCHAPIR] (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1820–1826).—2:3-Diphenylindene is synthesised by the dehydration with phosphoric oxide of  $\alpha\beta\gamma$ -triphenylpropane- $\alpha\beta$ -diol, m. p. 159–160°, prepared by the action of magnesium benzyl chloride on benzoin. Dehydration with acetyl chloride gives a 35% yield of the diphenylindene together with a 50% yield of monoacetate of the diol, m. p. 176–177°, which is the sole product of the action of acetic anhydride. R. T.

**Syntheses in the Indene Series. V.** A. P. ORÉKHOV (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1827–1829).—The method of the synthesis of indenenes from substituted bromopropanes by the elimination of hydrogen bromide, is applied with success to the synthesis of indones. The dibromide of benzylidenedeoxybenzoin,  $\text{COPh-CPhBr-CHPhBr}$ , is heated at 140–145°. A copious evolution of hydrogen bromide takes place and an 89% yield of 2:3-diphenyl-1-indene is obtained. R. T.

**Azulene.** ROLAND E. KREMERS (*J. Amer. Chem. Soc.*, 1923, 45, 717–723).—The isolation of azulene, b. p. 135.6°/1.1 mm., 167–168.4°/11 mm., from oil of milfoil (cf. Sherndal, A., 1915, i, 82, 702) has been slightly modified and the absorption spectrum plotted. The hydrocarbon, b. p. 130–140°/20 mm., produced by complete reduction by means of hydrogen and palladium, has the formula  $\text{C}_{15}\text{H}_{18}$  (cf. Sherndal, *loc. cit.*; also Augspurger, *Science*, 1915, 42, 100), and is dicyclic. Reduction may also be effected, at least partly, by means of sodium amalgam, but not by aluminium amalgam. Azulene forms ill-defined additive products with bromine, nitrogen trioxide, and nitrosyl chloride, and apparently

forms also a sodio-derivative from which the hydrocarbon is regenerated by means of hydroxylic reagents. The oxidation of azulene (for which the annexed formulæ are proposed) by means of alkaline potassium permanganate, leads to carbon dioxide, acetone, acetic acid, and (probably) methylphthalic acid.

W. S. N.

**The Binary Eutectics between Naphthalene, Iodoform, and Iodine.** A. M. VASILIEV (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1779—1785).—The melting points and the composition of the binary eutectic mixtures of naphthalene, iodoform, and iodine are determined, in order to test the accuracy of a theory put forward by Flavitzki (A., 1906, ii, 152). According to this theory, where  $t_1$ ,  $t_2$ , and  $t_3$  are the melting points of three substances, of molecular weight  $M_1$ ,  $M_2$ , and  $M_3$ ,  $t_{1-2}$ ,  $t_{2-3}$ , and  $t_{3-1}$ , the melting points of the eutectic mixtures obtained from each pair, and  $n_{1-2}M_1 + M_2$ ,  $n_{2-3}M_2 + M_3$ , and  $n_{3-1}M_3 + M_1$  are the compositions of these eutectics, the following expressions are obtainable:  $[n_{1-2}^2 M_1(t_1 - t_{1-2})]/[M_2(t_2 - t_{1-2})] = \alpha$ ,  $[n_{2-3}^2 M_2(t_2 - t_{2-3})]/[M_3(t_3 - t_{2-3})] = \beta$ ,  $[n_{3-1}^2 M_3(t_3 - t_{3-1})]/[M_1(t_1 - t_{3-1})] = \gamma$ .

According to Flavitzki, the product  $\alpha\beta\gamma$  should be equal to unity. The results obtained for the systems naphthalene-iodoform, iodoform-iodine, and iodine-naphthalene are in satisfactory agreement with this hypothesis,  $\alpha\beta\gamma$  being 1.113.

R. T.

**Action of Benzylidenemethylamine on certain Aromatic Nitro-derivatives.** MICHELE GIUA (*Gazzetta*, 1923, 53, i, 53—56).—The author has investigated the action of benzylidenemethylamine on 2 : 3 : 4- and 2 : 4 : 5-trinitrotoluenes, and 1-chloro- and 1-bromo-3 : 4 : 6-trinitrobenzenes. These compounds contain a labile nitro-group, and the last two also a labile halogen atom, which, however, is replaced less readily than the nitro-group. The reaction of the labile nitro-group with benzylidenemethylamine is similar to that with methylamine, and is expressed by the equations:  $\geq C \cdot NO_2 + CHPh \cdot NMe + H_2O \Rightarrow \geq C \cdot NHMe + Ph \cdot CHO + HNO_2$  and  $CHPh \cdot NMe + HNO_2 = Ph \cdot CHO + CH_3O + N_2$ . With the chloro- and bromo-trinitrobenzenes, the halogen atom also is replaced by NHMe if excess of the base is employed.

The hydrolysis of various bases, such as benzalazine, the phenylhydrazones, and benzylideneaniline by nitrohalogen compounds containing only the halogen atom in a labile condition was observed by Ciusa (A., 1906, i, 962), but these bases are not hydrolysed by nitro-compounds containing only a labile nitro-group. No hydrolysis of acetoxime, benzophenonephenylhydrazone, or benzylideneaniline occurs when these bases are heated with 2 : 3 : 4- or 2 : 4 : 5-trinitrotoluene, additive compounds being formed with the last two bases.

The interaction of benzylidenemethylamine and 2 : 3 : 4-trinitrotoluene yields 4 : 6-dinitromethyl-*m*-toluidine (cf. Brady and

Gibson, T., 1921, 119, 98); that of benzylidenemethylamine and 2:4:5-trinitrotoluene, 2:4-dinitromethyl-*m*-toluidine (Brady and Gibson, *loc. cit.*), and that of benzylidenemethylamine and 1-chloro-3:4:6-trinitrobenzene, 4:6-dinitrodimethyl-*m*-phenylenediamine (cf. Blanksma and Meerum Terwogt, A., 1902, i, 715).

5-Bromo-2:4-dinitromethylaniline,  $C_6H_3Br(NO_2)_2 \cdot NHMe$ , prepared from 1-bromo-3:4:6-trinitrobenzene and benzylidene-methylamine, forms yellow crystals, m. p. 149–150°. T. H. P.

**Action of Methyl Sulphate on Diphenylamine and on Diphenylmethylamine.** CHARLES STANLEY GIBSON and DUDLEY CLOETE VINING (T., 1923, 123, 831–837).

**Reactions of Strongly Electropositive Metals with Organic Substances in Liquid Ammonia Solution. I. Preliminary Investigations.** CHARLES A. KRAUS and GEORGE F. WHITE (J. Amer. Chem. Soc., 1923, 45, 768–778; cf. following abstract).—The action of sodium on solutions of various substances in liquid ammonia has been investigated, without, however, any generalisation being reached.

With the exception of triphenylmethane, which forms a sodio-derivative (cf. Schlenk and Thal, A., 1913, i, 1205), hydrocarbons and ethers are unaffected by sodium in ammonia solution; alcohols and phenols form alkoxides and phenoxides, respectively, with liberation of hydrogen. Aldehyde-ammonia forms a similar sodio-derivative, but the behaviour of benzaldehyde has not been fully investigated. The thiophenols form ammonium salts with liquid ammonia, and these are converted by sodium into the sodium salts with formation of hydrogen and regeneration of ammonia. In a similar manner, acetic acid (ammonium salt) gives sodium acetate and hydrogen. Sodium apparently forms an additive product with acetone, or with acetone and ammonia; this is decomposed by water. Propyl iodide gives rise to propane, *n*-hexane, and *n*-propylamine; *tert*-amyl iodide is converted into *sec*-pentane. Ethylene chloride and sodium apparently react quantitatively in liquid ammonia solution in accordance with the equation:  $C_2H_4Cl_2 + 2Na \rightarrow C_2H_4 + 2NaCl$ . Acetylene dibromide and sodium probably react as follows:  $C_2H_2Br_2 + 2Na \rightleftharpoons C_2H_2 + 2NaBr$ ;  $C_2H_2Br_2 + 4Na \rightarrow 2NaBr + C_2Na_2 + H_2$ ;  $C_2H_2 + 2Na \rightarrow H_2 + C_2Na_2$ . *o*-Chlorotoluene is converted into toluene and *o*-toluidine, *p*-chlorotoluene into toluene and *p*-toluidine; both reactions are probably to be expressed as follows:  $2C_6H_4MeCl + 2Na + NH_3 \rightarrow C_6H_5Me + C_6H_4Me \cdot NH_2 + 2NaCl$ . Similarly, dichlorobenzene gives benzene and *o*-phenylenediamine:  $2C_6H_4Cl_2 + 4Na + 2NH_3 \rightarrow C_6H_6 + C_6H_4(NH_2)_2 + 4NaCl$ . Nitrobenzene is reduced successively to azoxybenzene, azobenzene, hydrazobenzene, and aniline, or their sodio-derivatives.  $\alpha$ -Bromonaphthalene is partly converted into naphthalene, whilst from phenylthiocarbimide aniline and diphenyl (traces) are produced. Sodium benzene-sulphonate gives rise to benzene, traces of diphenyl, and sodium sulphite; phenyl sulphide gives benzene and sodium sulphide.

From the product of the action of ammoniacal sodium on benzyl chloride or benzonitrile, no definite compound has been isolated.

W. S. N.

**Reactions of Strongly Electropositive Metals with Organic Substances in Liquid Ammonia Solution. II. Action of Sodium on Phenyl Halides in Liquid Ammonia.** GEORGE F. WHITE (*J. Amer. Chem. Soc.*, 1923, 45, 779—784; cf. preceding abstract).—Sodium (1 atom) reacts with a phenyl halide (1 mol.) in liquid ammonia with formation of benzene and secondary and tertiary phenylamines, together with sodium halide and occasional traces of aniline, phenylcarbylamine, and sodium cyanide. The fundamental equations are:  $6\text{PhCl} + 6\text{Na} + \text{NH}_3 = 3\text{C}_6\text{H}_6 + \text{NPh}_3 + 6\text{NaCl}$ ;  $4\text{PhCl} + 4\text{Na} + \text{NH}_3 = 2\text{C}_6\text{H}_6 + \text{NPh}_2 + 4\text{NaCl}$ ; and as side-reactions:  $2\text{PhCl} + 2\text{Na} + \text{NH}_3 = \text{C}_6\text{H}_6 + \text{NH}_2\text{Ph} + 2\text{NaCl}$ . The benzene is a primary product, sodium phenyl not being produced. Benzene distils readily, and chlorobenzene and toluene distil slowly, from liquid ammonia mixtures. Diphenylamine and triphenylamine are partly miscible in the solid state, the limits of miscibility being approximately 13% and 75% of triphenylamine. A liquid phase containing 21% of triphenylamine is in equilibrium with the eutectic mixture at 43.6°. The formation of triphenylamine is favoured by dilution of the reaction mixture with light petroleum. Aniline and diphenylamine form sodio-derivatives in liquid ammonia solution.

W. S. N.

**The Synthesis of Optically Active Asparagines.** O. E. LUTZ (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1881—1887).—Various optically active *N*-substituted asparagines are synthesised by the action of aromatic amines on *l*-bromosuccinic acid. In this way, aniline gives *l*-phenylasparagine, m. p. 147—148°, anisidine gives *l*-anisylasparagine, m. p. 135°, and *m*-toluidine gives *l*-*m*-tolylasparagine, m. p. 160—161°. These substances slowly lose their *l*-rotatory power if kept for some time with mineral acids. R. T.

**$\beta$ -Arylamino-ethanols.** ROGER ADAMS and J. B. SEGUR (*J. Amer. Chem. Soc.*, 1923, 45, 785—790).— $\beta$ -Aminoethanols have been synthesised as follows: (1) the condensation of  $\beta$ -chloroethyl chloroformate with a primary amine in benzene solution, with formation of a  $\beta$ -chloroethyl carbamate; (2) the action of aqueous or alcoholic sodium or potassium hydroxide (1 mol.) on the  $\beta$ -chloroethyl carbamate, to give an oxazolidone; (3) the action of aqueous or alcoholic sodium or potassium hydroxide (4 mols.) on the oxazolidone. The last two reactions may be carried out in a single operation.

The following compounds are described.  $\beta$ -Chloroethyl *o*-tolylcarbamate, white needles, m. p. 45°, b. p. 209—210°/37 mm.  $\beta$ -Chloroethyl *p*-tolylcarbamate, white crystals, m. p. 61°.  $\beta$ -Chloroethyl *o*-chlorophenylcarbamate, white needles, m. p. 56.5—57°.  $\beta$ -Chloroethyl *p*-chlorophenylcarbamate, white needles, m. p. 62—63°.  $\beta$ -Chloroethyl *p*-ethoxyphenylcarbamate, white needles, m. p. 94°. 3-*o*-Tolyl-2-oxazolidone, straw-coloured oil, b. p. 180—185°/3 mm. 3-*p*-Tolyl-2-oxazolidone, white needles, m. p. 91°. 3-*o*-Chloro-

*phenyl-2-oxazolidone*, straw-coloured oil, b. p. 185—188°/3 mm.  
*3-p-Chlorophenyl-2-oxazolidone*, white needles, m. p. 118·5—119°.  
*3-p-Phenethyl-2-oxazolidone*, white crystals, m. p. 96°.  $\beta$ -*Anilinoethyl alcohol*, an oil, b. p. 280—285°/755 mm. or 167—170°/19 mm.  
 $\beta$ -*o-Toluidinoethyl alcohol*, an oil, b. p. 145—150°/3 mm.  $\beta$ -*p-Toluidinoethyl alcohol*, a straw-coloured oil, b. p. 153—155°/4 mm., and white plates, m. p. 42—43°.  $\beta$ -*o-Chloroanilinoethyl alcohol*, a straw-coloured oil, b. p. 148—152°/3 mm.  $\beta$ -*p-Chloroanilinoethyl alcohol*, white needles, m. p. 77—77·5°.  $\beta$ -*p-Phenetidinoethyl alcohol*, white crystals, m. p. 68·5—69°.

It is shown that the physiological properties of 3-p-phenethyl-2-oxazolidone are very similar to those of phenacetin. W. S. N.

**Decomposition of Aryl Formamides. Preparation of Substituted Carbamides.** A. MAILHE (*Compt. rend.*, 1923, 176, 689—691).—The catalytic decomposition of arylformamides, for example, formanilide, by alumina at 400° results mainly in the formation of aniline and carbon monoxide. Dehydration occurs to a relatively small extent with production of benzonitrile according to the scheme  $\text{H}\cdot\text{CO}\cdot\text{NHPh} \rightarrow \text{H}_2\text{O} + \text{PhNC} \rightarrow \text{PhCN}$ . The water produced also reacts to a slight extent with the carbylamine to give aniline and carbon monoxide, and with the formanilide to give aniline and formic acid, which in its turn is resolved into carbon dioxide and hydrogen. Contact with nickel at 340—350° also causes resolution of formanilide into aniline and carbon monoxide, but at 400—410° with rapid passage of the vapours, the aniline interacts with unchanged formanilide to give diphenylcarbamide:  $\text{H}\cdot\text{CO}\cdot\text{NHPh} + \text{PhNH}_2 \rightarrow \text{H}_2 + \text{CO}(\text{NHPh})_2$ , which crystallises in the outlet tubes and in the condensate. The formotoluidides behave in a perfectly analogous manner; *di-o-tolylcarbamide*, m. p. 243°, *di-m-tolylcarbamide*, m. p. 203°, and *di-p-tolylcarbamide*, m. p. 241°, were thus prepared. G. F. M.

**New Method of Preparing Tetra-substituted Carbamides.** A. MAILHE (*Compt. rend.*, 1923, 176, 903—905).—The catalytic decomposition by nickel at 400° (cf. preceding abstract) of formo-o-xylidide, m. p. 97°, gives *di-o-xylidylcarbamide*,  $\text{CO}(\text{NH}\cdot\text{C}_6\text{H}_3\text{Me}_2)_2$ , m. p. 236°, whilst formo-1-methyl-3-ethylphenyl-6-amide, m. p. 151°, yields *s-dimethylethylphenylcarbamide*, m. p. 215°. The formyl derivatives of secondary aromatic amines react in a precisely analogous manner giving tetra-substituted carbamides together with hydrogen, and carbon monoxide and dioxide, and a certain amount of regenerated amine according to the equations:  $\text{NMePh}\cdot\text{COH} = \text{CO} + \text{NHMePh}$ , and  $\text{NMePh}\cdot\text{COH} + \text{NHMePh} = \text{H}_2 + \text{CO}(\text{NMePh})_2$ . Thus methylformanilide, a yellow viscous liquid, b. p. 286°, gives a mixture of methylaniline and *diphenyldimethylcarbamide*,  $\text{CO}(\text{NMePh})_2$ , b. p. 245—246°. Ethyl-o-toluidine gives a formyl derivative, b. p. 272°, which is similarly catalysed to *di-o-tolyl-diethylcarbamide*, b. p. 258—260°, and 1-methyl-3-ethylphenyl-6-amine gives a formyl derivative, m. p. 141°, which is catalysed to *dimethylethylphenyldiethylcarbamide*,  $\text{CO}(\text{NEt}\cdot\text{C}_6\text{H}_3\text{MeEt})_2$ , a yellow liquid, b. p. 295°. G. F. M.

**The Constituents of Lignite Tars. Lignite Tar Creosote Oils.** R. AVENARIUS (*Z. angew. Chem.*, 1923, 36, 165—168).—

These oils are composed of phenols and small quantities of carboxylic acids, the latter occurring almost exclusively in low-temperature tars. Lignite itself has been shown to contain both phenols and acids (Hoffmann, *Z. angew. Chem.*, 1921, 34, 217; Erdmann, *ibid.*, 309, also *J. Soc. Chem. Ind.*, 1921, 570A). The carboxylic acids, extracted with sodium carbonate, undergo decomposition when distilled at atmospheric pressure and even to some extent on distillation under diminished pressure. They are readily converted into their methyl esters and these submitted to fractional distillation under diminished pressure, although here, as in the case of the free acids, a sharp separation is impossible. Fractions boiling within ranges of  $10^\circ$  were collected separately and analysed. The results show that the acids are monobasic and contain a decreasing percentage of hydrogen with increasing molecular weight. The lower fractions comprised mainly acids of the type  $C_nH_{2n-2}O_2$ , whilst the higher contained also those of the type  $C_nH_{2n-4}O_2$ . The presence of esters of unsaturated acids was shown by the behaviour of the fractions towards potassium permanganate and bromine. Treatment with the latter, followed by distillation, destroyed the esters of the unsaturated acids, leaving unaltered those of the acids of the type  $C_nH_{2n-2}O_2$ . The latter appeared to be saturated naphthenic acids (e.g. the esters  $C_9H_{13}\cdot CO_2Me$  and  $C_9H_{15}\cdot CO_2Me$ , boiling at  $103\text{--}106^\circ/13$  mm. and  $127\text{--}133^\circ/12$  mm., respectively, are found in the mixture of esters after treatment as above).

The crude phenols, containing water, were submitted to repeated fractional distillation under diminished pressure and the individual fractions treated, in absolute ethereal solution, with carbamyl chloride, whereby crystalline carbamic and allophanic esters were obtained. The former were fractionally crystallised from light petroleum or benzene (they are hydrolysed by boiling water), whilst the allophanates, which were insoluble in the above two solvents, were crystallised from dilute methyl alcohol. These esters were identified both by analysis and by comparison with the carbamates and allophanates of a number of homologues of phenol, synthesised specially for the purpose.

By these means phenol itself was found to be absent, whilst the occurrence of *m*-cresol and *p*-xylenol was proved. The aromatic, unlike the aliphatic, carbamic esters decompose in the neighbourhood of their m. p. When distilled, the original phenol and cyanic acid are produced, part of the latter polymerising and remaining in the distillation flask as cyanuric acid. This is a useful method for recovering phenols from their carbamic esters. A similar difference exists between aromatic and aliphatic allophanates. Thiophenols were found in the creosote oil, mainly in the higher fractions. The following esters were synthesised for reference: Phenyl carbamate, colourless needles, m. p.  $143^\circ$ . *o*-Tolyl carbamate, colourless needles, m. p.  $155^\circ$ . *m*-Tolyl carbamate,

colourless, lance-like crystals, m. p. 115—116°. *p*-Tolyl carbamate, colourless needles, m. p. 154°. *m*-4-Xylyl carbamate, colourless needles, m. p. 156°. *p*-Xylyl carbamate, colourless, star-like clusters of needles, m. p. 113—114°. *o*-4-Xylyl carbamate, needles, m. p. 123—133°.  $\psi$ -Cumyl carbamate, colourless needles, m. p. 151—152°. All these esters melt to clear liquids which become cloudy on further heating. *Allophanic* esters: *phenyl*, short, colourless needles, m. p. 178°. *p*-Tolyl, colourless needles, m. p. 199—200°. *m*-4-Xylyl, colourless needles, decomp. at about 220°. *p*-Xylyl, colourless needles, m. p. 203°. *o*-4-Xylyl, needles, m. p. 183°.  $\psi$ -Cumyl, colourless needles, m. p. 213°. W. T. K. B.

**Stereochemistry of Cyclic Alcohols, Aldehydes, and Carboxylic Acids.** A. SKITA (*Annalen*, 1923, 431, 1—30).—Use has been made of the method already described (A., 1922, i, 534) to determine the configurations of the six methylcyclohexanols, the hexahydro-*o*-toluic acids and the hexahydro-*p*-toluic acids, but the configuration of the only known form of hexahydro-*m*-toluic acid remains undecided.

[With H. HÄUBER and R. SCHÖNFELDER].—The reduction of *o*-cresol by means of colloidal palladium and hydrogen in neutral solution gives an 80% yield of 1-methylcyclohexan-2-one, together with traces of *cis*-1-methylcyclohexan-2-ol. Continued reduction under similar conditions of the ketone or of *o*-cresol leads to an 81% yield of *trans*-1-methylcyclohexan-2-ol, which is also produced in 81% yield when the ketone is reduced by means of sodium in moist ethereal solution. The reduction of *o*-cresol or of the ketone by means of palladium-hydrogen in acetic acid solution leads to a 75% yield of the *cis*-alcohol (above), which is converted by means of fuming hydriodic acid into *cis*-2-iodo-1-methylcyclohexane, yield 64%. This iodo-compound reacts with magnesium and carbon dioxide in ethereal solution to give a poor yield of *cis*-1-methylcyclohexane-2-carboxylic acid, which is also formed by the reduction of *o*-toluic acid by means of palladium-hydrogen in acetic acid solution, yield 83%. Incidentally, cyclohexane-carboxylic acid is prepared in 83% yield from benzoic acid by the same method. The *trans*-alcohol (above) yields the *trans*-iodo-derivative, from which *trans*-1-methylcyclohexane-2-carboxylic acid is prepared, in 20% yield. The ethyl ester of the *cis*-acid is reduced by means of sodium and alcohol in 38% yield to *cis*-1-methylcyclohexyl-2-carbinol, which is oxidised by means of chromic acid in acetic acid solution to *cis*-2-aldehydro-1-methylcyclohexane, yield 35%. Similarly, the ethyl ester of the *trans*-acid yields the *trans*-carbinol and the *trans*-aldehyde. The *cis*-acid is quantitatively converted into the *trans*-acid by treatment with gaseous hydrogen chloride.

*trans*-1-Methylcyclohexan-4-ol results from the reduction of *p*-cresol in neutral solution; in acid solution, the *cis*-alcohol is formed. From these, the *trans*-iodo- and the *cis*-iodo-derivatives, respectively, are formed by the action of fuming hydriodic acid; both iodo-compounds lead, however, to the same *trans*-1-methyl

cyclohexane-4-carboxylic acid. This acid is also produced by the action of gaseous hydrogen chloride on the mixture of *cis*-acid and *trans*-acid which is formed by the catalytic reduction of *p*-toluic acid in acid solution. The reduction of the amide of *p*-toluic acid by means of palladium-hydrogen in acid solution gives a 96% yield of the amide of *cis*-1-methylcyclohexane-4-carboxylic acid, which is converted by means of nitrous acid into the *cis*-acid; the latter, being unstable, is esterified before purification. The ethyl ester of the *trans*-acid, from which the *trans*-amide is prepared, and the ethyl ester of the *cis*-acid, both give, on reduction by means of sodium and alcohol, *trans*-1-methylcyclohexyl-4-carbinol in 38% yield; from this the *trans*-aldehyde is obtained on oxidation by means of chromic acid in acetic acid solution; yield 25%.

*m*-Cresol gives *cis*-1-methylcyclohexan-3-ol on reduction in acid solution, *trans*-1-methylcyclohexan-3-ol in neutral solution. Both these alcohols lead, by the action of hydriodic acid, to the same iodo-derivative, which is converted by treatment with magnesium and carbon dioxide in ethereal solution into the only known form (liquid) of 1-methylcyclohexane-3-carboxylic acid; the latter is also produced by the catalytic reduction of *m*-toluic acid in acid solution. The reduction of the ethyl ester of the acid by means of sodium and alcohol leads to 1-methylcyclohexyl-3-carbinol, which gives the corresponding aldehyde on oxidation.

A *heptanaphthenecarboxylic acid* from Balachany petroleum, *n*. p. 190—192°, amide, *m*. p. 126°, has been shown to be different from any of the five known hexahydrotoluic acids.

It is shown that the physical constants of the compounds dealt with conform, with few exceptions, to Auwers's generalisation A., 1920, i, 721).

The following compounds are new. *cis*-1-Methylcyclohexan-2-ol, *n*. p. 169.5—170.5° (corr.), and its phenylurethane, *m*. p. 95°. Phenylurethane of *trans*-1-methylcyclohexan-2-ol, *m*. p. 105°. *cis*-1-Iodo-1-methylcyclohexane, *b*. p. 96°/30 mm. *cis*-1-Methylcyclohexyl-2-carbinol, *b*. p. 188—189°; its benzoate, an oil. *cis*-2-Aldehydo-methylcyclohexane, *b*. p. 70°/24 mm., semicarbazone, *m*. p. 137—38°. *trans*-1-Methylcyclohexyl-2-carbinol, *b*. p. 192—192.5°, benzoate, an oil. *cis*-1-Methylcyclohexan-4-ol, *b*. p. 173.5—173.8°, phenylurethane, *m*. p. 98°. Phenylurethane of *trans*-1-methylcyclohexan-4-ol, *m*. p. 124—125°. *trans*-1-Methylcyclohexyl-4-carbinol, *n*. p. 197.5—198.5°, benzoate, an oil. *trans*-4-Aldehydo-1-methylcyclohexane, *b*. p. 75—76°/24 mm., semicarbazone, *m*. p. 183°. Phenylurethane of *cis*-1-methylcyclohexan-3-ol, *m*. p. 91°. Phenylurethane of *trans*-1-methylcyclohexan-3-ol, *m*. p. 76°. 1-Methylcyclohexyl-3-carbinol, *b*. p. 198—199°, benzoate, an oil. 3-Aldehydo-methylcyclohexane, *b*. p. 95°/35 mm., and its semicarbazone, *m*. p. 75.5°.

W. S. N.

The Fusion Curves of Binary Mixtures of  $\alpha$ -Nitronaphthalene with the three Dihydroxybenzenes and of the Dihydroxybenzenes with Each Other. PIERRE SENDEN (*Bull. Soc. chim. Belg.*, 1923, 32, 97—102).—A study of the fusion curves of binary

mixtures of  $\alpha$ -nitronaphthalene, quinol, resorcinol, and pyrocatechol leads to the conclusion that no compounds are formed between any two of these substances. H. J. E.

**The Methylating and Sulphonating Action of Methyl Sulphate on Phenols in the Absence of Water.** L. J. SIMON and M. FRÉJACQUES (*Compt. rend.*, 1923, 176, 900—902).—The action of methyl sulphate on phenol at 100—120° in the absence of water and alkali gives rise to numerous products owing to the superposition of a sulphonating action on the normal methylating action of this reagent. Both the phenol and the anisole formed from it are in part converted into sulphonic acids, and a proportion of the latter is methylated, so that the reaction mixture contains the free sulphonic acids of both phenol and anisole and their methyl esters, together with methyl hydrogen sulphate and sulphuric acid, and methyl ether is evolved, according to the equations:  $\text{PhOH} + \text{Me}_2\text{SO}_4 = \text{PhOMe} + \text{MeHSO}_4$ ;  $\text{PhOMe} + \text{Me}_2\text{SO}_4 = \text{OMe} \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_3\text{H} + \text{Me}_2\text{O}$ ;  $\text{PhOH} + \text{Me}_2\text{SO}_4 = \text{OH} \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_3\text{H} + \text{Me}_2\text{O}$ ;  $\text{OMe} \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_3\text{H} + \text{Me}_2\text{SO}_4 = \text{OMe} \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_3\text{Me} + \text{MeHSO}_4$ ;  $\text{OH} \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_3\text{H} + \text{Me}_2\text{SO}_4 = \text{OH} \cdot \text{C}_6\text{H}_4 \cdot \text{SO}_3\text{Me} + \text{MeHSO}_4$ . Treatment of anisole by methyl sulphate in the same way gives the same products but in different proportions, and the formation of phenol sulphonic acid shows that a demethylating action occurs to some extent. A similar series of products was obtained from the cresols. The methyl sulphonates are crystalline substances, which distil at 150—160°/1—2 mm. Methyl phenolsulphonate melts at 95°, methyl anisolesulphonate at 30°, the corresponding derivatives from *o*-cresol at 93° and 58° respectively, and from *p*-cresol at 70° and 70° respectively. The methyl sulphonates are themselves methylating agents, readily giving substituted methylamines with primary amines such as aniline and *o*-toluidine, and methyl ethers with phenols in presence of an alkali. G. F. M.

**The Reactions of Esters with Organomagnesium Derivatives.** V. G. L. STADNIKOV (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1870—1874; cf. A., 1914, i, 954; 1916, i, 259, 260; 1917, i, 136).—Ethyl formate is allowed to react with magnesium phenyl bromide in the presence of a small quantity of iodine. The products of this reaction are benzhydryl ethyl ether and dibenzhydryl ether. The formation of these substances is due to the formation of some benzhydryl iodide, which reacts with the bromomagnesium ethoxide produced in the first part of the reaction giving the mixed ether, or with bromomagnesium benzhydryloxy to give the simple ether. The formation of benzhydryl iodide as an intermediate product of the reaction is proved by the formation of tetraphenylethane in the following reaction. Iodomagnesium benzhydryloxy is prepared from excess of magnesium, benzhydryl, and iodine, ethyl formate is added, and the solution boiled. A number of tarry products are formed, from which tetraphenylethane (formed by the elimination of iodine from two molecules of benzhydryl iodide) is separated. The reaction between magnesium  $\alpha$ -naphthyl bromide and ethyl formate gave a quantity of tarry matter from

which some ethyl di- $\alpha$ -naphthylmethyl ether is isolated. This is formed in the same way as the corresponding diphenyl substance in the previous experiment.

R. T.

\* **The Reactions of Iodomagnesium Alkylloxides with Esters.** II. G. L. STADNIKOV (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1875—1881); cf. A., 1915, i, 975).—Iodomagnesium menthyloxide is formed by the action of menthol on magnesium methyl iodide, and an excess of ethyl formate is added. After boiling for twenty hours, menthyl formate is separated from the reaction mixture. Iodomagnesium triphenylcarbinyl oxide is prepared from triphenylcarbinol and magnesium methyl iodide. To this ethyl formate and a little iodine are added, and the mixture is boiled for forty hours. A variety of products results, from which triphenylcarbinyl peroxide is isolated, produced by the action of atmospheric oxygen on the hexaphenylethane formed by the elimination of iodine from two molecules of triphenylcarbinyl iodide. A larger yield of the peroxide is obtained by repeating the previous reaction in the presence of excess of magnesium, and at the same time some ethyl triphenylcarbinyl ether is formed. Iodomagnesium benzhydryloxide is prepared by the action of benzhydrol on magnesium methyl iodide, and is boiled for thirty hours with ethyl formate. In the reaction products, tetraphenylethane, formed from two molecules of benzhydryl iodide by the elimination of iodine, is found, together with dibenzhydryl ether and benzhydryl ethyl ether, formed by the interaction of iodomagnesium ethoxide with benzhydryl formate. On repeating this reaction, using an excess of magnesium, an increased yield of tetraphenylethane is obtained, proving that benzhydryl iodide is an intermediate product in the formation of the ethers. The same reaction was repeated, using ethyl acetate instead of ethyl formate, and resulted in the production of tetraphenylethane and of a quantity of tarry matter from which no identifiable product was isolated.

R. T.

**$\beta$ -Hydroxyarylethylamines.** O. HINSBERG (U.S. Pat. 1432291).—The following  $\beta$ -hydroxyarylethylamines are prepared by interaction of aminoacetal with phenols in the presence of sulphuric, hydrochloric, or acetic acid: From phenol,  $\beta\beta$ -di-*p*-hydroxyphenylethylamine, m. p. about 95°; from thymol, di-4-hydroxy-3-isopropylphenylethylamine, colourless needles, m. p. 220°. From *m*-aminophenol,  $\beta$ -hydroxy- $\beta$ -2-amino-4-hydroxyphenylethylamine, flakes. From pyrocatechol,  $\beta$ -hydroxy- $\beta$ -di-*o*-hydroxyphenylethylamine, m. p. 190°. From pyrogallol,  $\beta$ -hydroxy- $\beta$ -trihydroxyphenylethylamine, very unstable. From gallic acid,  $\beta$ -hydroxy- $\beta$ -trihydroxycarboxyphenylethylamine, which is not precipitated when ammonia is added to an aqueous solution of the hydrochloride. Methylaminoacetal and pyrocatechol yield  $\beta$ -hydroxy- $\beta$ -di-*o*-hydroxyphenylmethylethylamine and  $\beta\beta$ -di-*o*-hydroxyphenylmethylethylamine, which can be separated by fractional crystallisation of the hydrochlorides, the former (adrenaline) being the non-crystallising portion. *N*-Diisamylaminoacetal and pyrogallol yield  $\beta$ -hydroxy- $\beta$ -trihydroxy-

*phenylethyl-diisoomylamine* which is precipitated in flakes by the addition of ammonia to a solution of the hydrochloride.  $\beta\beta$ -Di-2-hydroxynaphthylethylamine, from aminoacetal and  $\beta$ -naphthol, has m. p. about  $124^{\circ}$ . Interaction of sodium  $\alpha$ -naphthol-8-sulphonate and aminoacetal, followed by addition of hydrochloric acid and washing with water, yields a *product*, m. p. above  $250^{\circ}$ .

CHEMICAL ABSTRACTS.

**Naphthenic Acids Derived from Japanese Petroleum.** YOSHIO TANAKA and SHOICHIRO NAGAI (*J. Amer. Chem. Soc.*, 1923, 45, 754—756; *J. Chem. Ind. Japan*, 1922, 25, 1031—1044).—By acidifying the waste lyes from the Akita petroleum refinery, a crude mixture of petroleum acids is obtained. Neutral impurities are removed by converting the crude acids into the potassium salts and extracting the aqueous-alcoholic solution by means of light petroleum. The acids are reprecipitated by acidification, and alkyl-sulphuric acids removed by distilling the mixture under reduced pressure after the addition of copper oxide. The distillate is again converted into the potassium salts and the aqueous solution extracted by means of light petroleum. The crude acid produced on acidification is fractionally distilled and the fraction b. p.  $170$ — $220^{\circ}/9$  mm. is converted into a mixture of methyl esters. These are then separated by repeated fractional distillation. *Methyl tridecanaphthenate*, b. p.  $124$ — $126^{\circ}/9$  mm. or  $262$ — $263^{\circ}/760$  mm.,  $d_4^{25}$  0.9622,  $n_D^{25}$  1.4663; *methyl tetradecanaphthenate*, b. p.  $135$ — $137^{\circ}/9$  mm. or  $277$ — $278^{\circ}/760$  mm.,  $d_4^{25}$  0.9644,  $n_D^{25}$  1.4686, and *methyl pentadecanaphthenate*, b. p.  $147$ — $149^{\circ}/9$  mm. or  $296$ — $297^{\circ}/760$  mm.,  $d_4^{25}$  0.9659,  $n_D^{25}$  1.4728, are colourless liquids, possessing a fruity odour. The pure naphthenic acids are obtained as colourless, odourless liquids by hydrolysis of the esters by means of 2*N*-alcoholic potassium hydroxide solution. *Tridecanaphthenic acid*, b. p.  $167$ — $169^{\circ}/9$  mm.,  $d_4^{25}$  0.9916,  $n_D^{25}$  1.4784; *tetradecanaphthenic acid*, b. p.  $178$ — $180^{\circ}/9$  mm.,  $d_4^{25}$  0.9930,  $n_D^{25}$  1.4807, and *pentadecanaphthenic acid*, b. p.  $191$ — $192^{\circ}/9$  mm.,  $d_4^{25}$  0.9941,  $n_D^{25}$  1.4848, have no iodine number, and are not discoloured on exposure to the air.

W. S. N.

**Decomposition of Aminobenzoic Acids by Boiling Water.** L. McMASTER and R. L. SHRINER (*J. Amer. Chem. Soc.*, 1923, 45, 751—753).—*o*-Amino- and *p*-amino-benzoic acids, but not *m*-aminobenzoic acid, are decomposed by boiling water into aniline and carbon dioxide; the reaction is unimolecular, the *ortho*-acid decomposing twice as fast as the *para*-acid. Both *o*-aminobenzoic acid and *p*-aminobenzoic acid are slightly volatile in steam, whilst *m*-aminobenzoic acid is not.

W. S. N.

**Catalysis and Steric Hindrance.** G. VAVON and A. HUSON (*Compt. rend.*, 1923, 176, 989—991).—The catalytic hydrogenation by means of platinum black of cinnamic acid derivatives was studied from the point of view of steric hindrance. The method adopted consisted in mixing 1 mol. proportion of the substance to be studied with 1 mol. of pinene, and after the fixation of 1 mol.

of hydrogen the proportion of the cinnamic acid derivative hydrogenised compared with the total amount of the mixed substances hydrogenised was determined by an observation of the change of rotation produced. The results obtained were strictly in accordance with the theory of steric hindrance, as is seen from the following figures which express the percentage which the dihydrocinnamic acid derivative forms of the total substances hydrogenised: *Series 1.* Cinnamic acid 57,  $\beta$ -methylcinnamic acid 26,  $\alpha$ -methylcinnamic acid 22,  $\alpha\beta$ -dimethylcinnamic acid 19. *Series 2.* Methyl cinnamate 63, methyl  $\beta$ -methylcinnamate 45, ethyl  $\alpha$ -methylcinnamate 26. *Series 3.* Ethyl cinnamate 58, ethyl  $\beta$ -methylcinnamate 31, methyl  $\alpha$ -methylcinnamate 22. *Series 4.* Methyl cinnamate 61, ethyl cinnamate 56, isobutylcinnamate 50, cyclohexylcinnamate 40.

G. F. M.

**Ketens. XLIV. Inorganic Substituted Ketens. H. STAUDINGER and H. SCHNEIDER** (*Helv. Chim. Acta*, 1923, 6, 304—315).—It was to be expected that ketens with inorganic substituent groups such as halogen or hydroxyl would be comparatively stable substances, but this proves not to be the case. Halogen atoms decrease the stability and deepen the colour of ketens. Dichloroketen apparently cannot exist, chloroethylketen is very unstable, bromomethylketen is somewhat more stable and can be isolated. Oxygen-substituted ketens are extremely unstable; the existence of phenoxyethylketen and of diphenoxyketen have been established, but they could not be isolated.

*Diphenylacetic-bromoethylmalonic anhydride* decomposes at 88—89°. By distilling this at 15 mm., *bromoethylketen* was obtained as a reddish-brown, very unstable liquid, b. p.  $-40^\circ$  at 0.03 mm. With aniline, it gives *bromoisobutyranilide*, m. p. 97—98°; with alcohol, it gives ethyl  $\alpha$ -bromoisobutyrate. *Ethoxymethylmalonic acid* has m. p. 112°; with diphenylketen, it forms *diphenylacetic-ethoxymethylmalonic anhydride*, m. p. 86°. No trace of ethoxymethylketen could be obtained by heating the anhydride. *Diethoxymalonic acid* has m. p. 159° (decomp.); *diphenylacetic-diethoxymalonic anhydride* melts with slight decomposition at 101—102°; it gave no diethoxyketen when heated. *Ethyl phenoxyethylmalonate*, b. p. 170—180°/12 mm., was obtained by boiling ethyl bromoethylmalonate with sodium phenoxide solution; *phenoxyethylmalonic acid* forms crystals, m. p. 106°; *diphenylacetic-phenoxyethylmalonic anhydride* crystallises in long needles, decomposing at 94°. Phenoxyethylketen could not be obtained directly from this, but its formation was proved by heating the anhydride with benzophenone-aniline, when the  $\beta$ -lactam of  $\beta$ -anilino- $\alpha$ -phenoxy- $\beta\beta$ -diphenyl- $\alpha$ -ethylpropionic acid was obtained, colourless needles, m. p. 164°. No  $\beta$ -lactam could be obtained with benzyldeneaniline, or even with the more reactive *p*-methoxybenzyldeneaniline; these did not react with sufficient rapidity with the fugitive keten.

*Methyl diphenoxymalonnate* was prepared from methyl dibromomalonate and sodium phenoxide in methyl alcohol solution; it has m. p. 86°. *Diphenoxymalonic acid*, m. p. 173°, forms, with

diphenylketen, *diphenylacetic-diphenoxymalonic anhydride*, decomposing at 79°. Diphenoxyketen was not isolated, but its formation was proved by obtaining its aniline derivative, *diphenoxyacetanilide*, which was also prepared from diphenoxyacetic acid; it forms white crystals, m. p. 120°. By heating the above anhydride with benzylideneaniline,  $\beta$ -*anilino- $\alpha\alpha$ -diphenoxy- $\beta$ -phenylpropionic- $\beta$ -lactam*, white crystals, m. p. 165°, was obtained, and with methoxybenzylideneaniline,  $\beta$ -*anilino- $\alpha\alpha$ -diphenoxy- $\beta$ -anisoylpropionic- $\beta$ -lactam*, colourless crystals, m. p. 143°. E. H. R.

**Ketens. XLV. Attempts to Prepare an Alleneketen.** H. STAUDINGER and H. SCHNEIDER (*Helv. Chim. Acta*, 1923, 6, 316—321).—Attempts to prepare a keten containing the allene structure, by heating the mixed anhydride from benzylidenemalonic acid and diphenylketen were unsuccessful; instead of the keten,  $\text{Ph}\cdot\text{CH}\cdot\text{C}\equiv\text{C}\cdot\text{O}$ , only diphenylketen could be obtained. No better result was obtained by heating *benzylidenemalonic-acetic anhydride*, obtained as a yellow syrup from sodium benzylidenemalonate and acetyl bromide. *Benzylidenemalonic anhydride*,  $\text{C}_{10}\text{H}_6\text{O}_3$ , was obtained by the action of oxalyl chloride on silver benzylidenemalonate in benzene. It forms a pale yellow, hygroscopic, amorphous powder, and is apparently highly polymerised. When heated, it decomposes without formation of any benzylideneketen. When silver benzylidenemalonate is distilled under reduced pressure, it decomposes, among the products being cinnamic acid and phenylacetylene. Attempts to apply the mixed malonic anhydride method to the preparation of isopropylideneketen from isopropylidenemalonic acid failed.

Attempts were also made to apply the same method to the preparation of ketens containing the grouping  $-\text{N}\cdot\text{C}\equiv\text{C}\cdot\text{O}$ . Phenylhydrazinomalonic acid,  $\text{NHPh}\cdot\text{N}\cdot\text{C}(\text{CO}_2\text{H})_2$ , failed to react with diphenylketen and when the mixture was heated only a tar was obtained. *Diphenylhydrazinomalonic acid* was prepared by condensing mesoxalic acid with *as*-diphenylhydrazine in aqueous methyl alcohol; it forms fine needles, m. p. 164°. It decomposes in aqueous solution forming carbon dioxide, hydrocyanic acid, and diphenylamine. It does not react in the cold with diphenylketen; in the hot, complete decomposition occurs. No keten could be obtained from isonitrosobenzylmalonic acid by the action of diphenylketen. E. H. R.

**Utilisation of *p*-Dichlorobenzene for Synthesis in the Diphenic Acid Series.** EDWARD B. HUNN (*J. Amer. Chem. Soc.*, 1923, 45, 1024—1030).—*p*-Dichlorobenzene is converted successively into 2:5-dichloronitrobenzene, 4-chloro-2-nitroaniline, 4-chloro-2-nitrobenzonitrile, 4-chloro-2-nitrobenzoic acid, and 4-chloro-2-aminobenzoic acid; the latter is diazotised in dilute aqueous sulphuric acid solution and the diazotised solution gradually added at 20° to an ammoniacal solution of cuprous oxide. The product is 5:5'-*dichlorodiphenic acid*, straw-coloured plates, m. p. 297°; *anhydride*, nearly colourless needles, m. p. 206° (corr.). 2-Amino-4-chlorobenzamide, colourless, oblong plates, m. p. 181.5° (corr.), is

formed by the action of iron and acetic acid on 4-chloro-2-nitrobenzonitrile, in attempting to prepare 4-chloro-2-aminobenzonitrile. The benzoyl derivative of 4-chloroanthranilic acid, colourless needles, m. p. 223.5° (corr.), and the methyl ester, colourless needles, m. p. 68.5°, are also described.

W. S. N.

**The Molecular Configuration of Polynuclear Aromatic Compounds. II. 4:6:4'-Trinitrodiphenic Acid and its Resolution into Optically Active Components.** GEORGE HALLATT CHRISTIE and JAMES KENNER (T., 1923, 123, 779—785).

**Chemistry of Polycyclic Structures in Relation to their Homocyclic Unsaturated Isomerides. IV. The Simulation of Benzenoid Properties by the Five-carbon Intra-annular Nucleus.** CHRISTOPHER KELK INGOLD, ERNEST ARTHUR SEELBY, and JOCELYN FIELD THORPE (T., 1923, 123, 853—874).

**Equilibrium between Benzaldehyde and Benzoin.** ERNEST ANDERSON and RALPH A. JACOBSON (*J. Amer. Chem. Soc.*, 1923, 45, 836—839).—The benzoin condensation is a reversible process; the equilibrium constant between benzaldehyde and benzoin at 79° is very nearly 0.245. The reagents are brought to equilibrium in 95% alcohol in an atmosphere of nitrogen; the benzoin is determined by precipitation by means of water. When benzaldehyde serves as starting material, equilibrium is reached in one hour, but when benzoin is used, 1.5 hours are required. The usual catalyst, sodium cyanide, is utilised. The solvent used in the most satisfactory method for preparing benzoin is 50% alcohol, from which the product is precipitated.

W. S. N.

**Dihydroxyphenones and Derivatives.** B. H. GNAGY (*J. Amer. Chem. Soc.*, 1923, 45, 805—808).—The preparation is described (cf. Goldzweig and Kaiser, A., 1891, 447) of 2:4-dihydroxy-1-propiofenone, which reacts, in acetic acid solution, with bromine to give 3:5-dibromo-2:4-dihydroxy-1-propiofenone, white crystals, m. p. 148°, *phenylhydrazone*, rosettes of small, short, greenish-yellow needles, m. p. 173°, decomp. The action of resorcinol on butyric acid in the presence of zinc chloride leads to the formation of 2:4-dihydroxy-1-butyrophenone, *phenylhydrazone*, m. p. 191—193°, decomp., which reacts with bromine in acetic acid solution to give 3:5-dibromo-2:4-dihydroxy-1-butyrophenone, silky needles, m. p. 113°, *phenylhydrazone*, yellow, hexagonal crystals, m. p. 155°.

W. S. N.

**Ketens. XLII. The Preparation of Ketens from Malonic Anhydrides.** H. STAUDINGER, H. SCHLUBACH, and H. SCHNEIDER (*Helv. Chim. Acta*, 1923, 6, 287—290).—It was shown some years ago (A., 1913, i, 1339) that dialkylketens could be prepared by heating the mixed anhydrides obtained by the action of diphenylketen on dialkylmalonic acid. Attempts to apply this method to the preparation of aldoketens from mono-substituted malonic acids have failed, since mixed anhydrides are not obtained by the

action of diphenylketen on mono-substituted malonic acids. The reaction failed with methyl-, ethyl-, phenyl-, benzyl-, chloro-, bromo-, and ethoxy-malonic acids as well as with malonic acid itself. In every case, only diphenylacetic anhydride was obtained. The probability is that, by the action of diphenylketen on a mono-substituted malonic acid, a ketencarboxylic acid is formed thus:  $\text{RCH}(\text{CO}_2\text{H})_2 + 2\text{Ph}_2\text{C}:\text{CO} \rightarrow \text{RC}(\text{CO}_2\text{H})_2\text{CO} + (\text{Ph}_2\text{CH}\cdot\text{CO})_2\text{O}$ , the ketencarboxylic acid then forming high-molecular polymerisation products.

In the preparation of sparingly volatile ketens such as dibenzylketen by the above method, difficulty is sometimes experienced on account of the decomposition of diphenylacetic anhydride into diphenylacetic acid and diphenylketen, the latter distilling over whilst the free acid combines with the new keten. In such cases, it has been possible to extract the keten from the anhydride with a solvent. Dichloro- and diethoxy-ketens could not be obtained; they probably cannot exist, since by the method employed a keten such as ethylchloroketen, which has only a short life at  $-80^\circ$ , can be isolated. Very unstable ketens can be recognised by combining them with Schiff's bases, with which they form well crystallised  $\beta$ -lactams.

Attempts to obtain mixed anhydrides of malonic acid with acetic, isobutyric, or benzoic acid were unsuccessful. With oxalic acid, a mixed anhydride was obtained which decomposed, giving a mixture of carbon monoxide and dioxide.

Acetylenedicarboxylic acid reacts slowly with diphenylketen; a crystalline mixed anhydride is not formed, but when the mixture is heated a little carbon suboxide is obtained. Acetonedicarboxylic acid does not form a mixed anhydride with diphenylketen, nor could the expected diketocyclobutane be obtained as a decomposition product of the mixture.

E. H. R.

**Ketens. XLIII. Alkyl- and Aryl-substituted Ketoketens.** H. STAUDINGER, H. SCHNEIDER, P. SCHOTZ, and P. M. STROSC (*Helv. Chim. Acta*, 1923, 6, 291—303).—To determine the influence of substituents on the stability and colour of disubstituted ketens, a number of new ketens have been prepared by the decomposition of mixed anhydrides (cf. previous abstract). The stability of the ketens increases considerably with the weight of the alkyl groups in dialkylketens. Whilst at  $25^\circ$  dimethylketen polymerises to the extent of 70% in six hours, diethylketen polymerises only 28% in twenty days and dipropylketen 9% in twenty-eight days. The reactivity towards Schiff's bases decreases with increasing molecular weight, but the colour is unchanged. Dibenzylketen, on the other hand, is less stable than dimethylketen, and in a few hours changes completely into diketotetrabenzylcyclobutane. The influence of the phenyl group is remarkable, for whilst diphenylketen polymerises very slowly, it is more reactive than dimethylketen. In the side chain, the phenyl group diminishes the stability of the keten whilst increasing the reactivity of the ethylene linking. The behaviour of the substituted ketens is paralleled by that of

the corresponding carbimides, of which benzylcarbimide is the most unstable. Diallylketen is a great deal more stable than libenzylketen, polymerising 75% in five days. The instability of the latter cannot therefore be attributed to the  $\beta$ -double bond.

*Diphenylacetic-methylethylmalonic anhydride*,  $C_{20}H_{20}O_4$ , was obtained by adding diphenylketen (2 mols.) to cold methylethylmalonic acid (1 mol.) in ether, and allowing the resulting solution to crystallise. Other mixed anhydrides were prepared similarly. It melts at  $82^\circ$  (decomp.). *Methylethylketen* was obtained by distilling the mixed anhydride under reduced pressure and collecting the distillate at  $-80^\circ$ ; it has b. p.  $-26^\circ$  to  $-28^\circ/12$  mm. *Diphenylacetic-dipropylmalonic anhydride* can be crystallised from a mixture of carbon disulphide and light petroleum; it decomposes at  $84^\circ$ . When distilled under reduced pressure, it gives *dipropylketen*, a yellow liquid with a suffocating odour, b. p.  $30^\circ/11$  mm., the yield being 32% of theory. The yield was determined by converting the keten with aniline into *dipropylacetanilide*, m. p.  $63-104^\circ$ . The polymerisation product of the keten, *diketotetrapropylcyclobutane*, forms colourless crystals, m. p.  $61-62^\circ$ . *Diphenylacetic-dibenzylmalonic anhydride* forms colourless crystals decomposing at  $104^\circ$ . *Dibenzylketen* (cf. preceding abstract) is a bright yellow, mobile liquid, b. p.  $121-122^\circ/0.09$  mm. When the decomposition of the mixed anhydride takes place in presence of benzylidene-aniline, the  $\beta$ -lactam of  $\beta$ -anilino- $\beta$ -phenyl- $\alpha$ -dibenzylpropionic acid,  $NPh \langle \begin{smallmatrix} CHPh \\ CO \end{smallmatrix} \rangle C(CH_2Ph)_2$ , is formed, white needles, m. p.  $121^\circ$ . *Diphenylacetic-benzylmethylmalonic anhydride* forms white needles, m. p.  $91^\circ$ . *Benzylmethylketen* is a yellow, mobile fluid with a suffocating odour, b. p.  $45-47^\circ/0.1$  mm. *Diphenylacetic-diallylmalonic anhydride* decomposes at  $95-96^\circ$ . *Diallylketen* is a mobile liquid of unpleasant odour, b. p.  $29-30^\circ/9$  mm., or  $131^\circ/716$  mm., but the latter value is not exact, as some polymerisation occurs. At very low temperatures, it forms a colourless, crystalline mass, m. p.  $-123^\circ$ . *Diallylacetanilide*, prepared to determine the yield of keten (80% theory) has m. p.  $75-76^\circ$ . *Diketotetra-allylcyclobutane* is a colourless liquid, b. p.  $135^\circ/9$  mm. *Ethyl methylallylmalonate*, from ethyl allylmalonate and methyl iodide, has b. p.  $112-115^\circ/17$  mm. *Methylallylmalonic acid* forms white crystals, m. p.  $74-76^\circ$ . *Diphenylacetic-methylallylmalonic anhydride* decomposes at  $69-70^\circ$ . *Methylallylketen* is a suffocating, yellow liquid, polymerising to the extent of 69% in twenty-four hours at  $30^\circ$ . The mixed anhydride from phenylmethylmalonic acid and diphenylketen decomposes in the cold and gives a 75% yield of phenylmethylketen. An attempt to prepare dimethyleneketene from cyclopropanedicarboxylic-diphenylacetic anhydride, white needles, m. p.  $81^\circ$ , was unsuccessful. E. H. R.

**Dioximes. IV. G. PONZIO** (*Gazzetta*, 1923, 53, i, 15-19).—It has been shown previously (A., 1922, i, 1037) that the assumption that the  $\beta$ -oximino-group of  $\alpha$ -benzoylmethylglyoxime may exist in the form  $:CH:NO$  suffices to explain the conversion of this

glyoxime into  $\alpha$ -oximino- $\beta$ - $\psi$ -nitroso- $\alpha$ -keto- $\alpha$ -phenylbutane by the action of nitrogen tetroxide. The fact that  $\alpha$ -benzoylmethylglyoxime loses a molecule of water and yields 4-nitroso-5-phenyl-3-methylisooxazole when treated with either acetic anhydride or anhydrous hydrochloric acid may also be explained on the same assumption:

On the other hand, the  $\beta$ - $\gamma$ -dioximino- $\alpha$ -keto- $\alpha$ -phenylbutane structure is supported by the fact that the first of these reagents yields also the diacetyl compound, m. p. 113° (*loc. cit.*), whilst, with both reagents, loss of water occurs likewise in another way,

giving benzoylmethylfurazan,  $\text{O} \begin{array}{c} \text{N:CMe} \\ \text{N:Cbz} \end{array}$ . Both these anhydrides are formed simultaneously when the  $\alpha$ -glyoxime is heated either to the melting point or with water at 80—90°, but under such conditions the formation of the isooxazole compound is manifested only by a transitory bluish-green coloration.

$\beta$ -Benzoylmethylglyoxime (m. p. 193°), which is converted by the action of nitrogen tetroxide into the peroxide,

melts without becoming green, and by acetic anhydride is converted completely into the diacetyl derivative, m. p. 68° (*loc. cit.*), no trace of nitrosoisooxazole being formed. When either heated with acetic anhydride or fused, it is transformed also into benzoylmethylfurazan, whilst the action of anhydrous hydrochloric acid yields a small proportion of 4-nitroso-5-phenyl-3-methylisooxazole in consequence of the preliminary isomerisation of part of the glyoxime into the  $\alpha$ -form.

4-Nitroso-5-phenyl-3-methylisooxazole,  $\text{C}_{10}\text{H}_8\text{O}_2\text{N}_2$  (see above), forms long, flattened, intensely blue needles, m. p. 84°; in the solid state it rapidly undergoes change to a green, and then to an almost colourless, oily substance, and when boiled with dilute sodium hydroxide solution it yields ammonia and benzoic acid.

Benzoylmethylfurazan,  $\text{C}_{10}\text{H}_8\text{O}_2\text{N}_2$  (see above), crystallises in large, white prisms of slight and not unpleasant odour, m. p. 42°, b. p. about 255° (slight decomp.), and is extremely resistant towards even concentrated acids, permanganate in sulphuric acid solution, and chromic acid dissolved in acetic acid, but is decomposed by alkali hydroxide, rapidly when heated, into ammonia and benzoic acid. Its phenylhydrazone,  $\text{C}_{15}\text{H}_{14}\text{ON}_4$ , exists in two modifications: the labile  $\alpha$ -form crystallises in long, golden-yellow needles, m. p. 101°; boiling dilute hydrochloric acid reconverts it into benzoylmethylfurazan, whilst 20% sodium hydroxide solution decomposes it with liberation of ammonia, the bulk of the hydrazone being transformed into the  $\beta$ -form by either of these reagents. The stable  $\beta$ -modification, which is obtained also when the  $\alpha$ -form is heated slightly above its melting point, separates in white or pale yellow laminae, m. p. 214°, and is not sensibly altered when boiled with 20% sodium hydroxide or hydrochloric acid solution. The

*p*-nitrophenylhydrazone,  $C_{16}H_{13}O_3N_3$ , forms flattened, yellow needles, m. p. 178–182°, reddens superficially in the light, and yields a deep violet solution when suspended in sodium hydroxide solution and treated with a little alcohol. The *dinitrophenylhydrazone*,  $C_{18}H_{13}O_5N_5$ , obtained by the action of nitric acid (d 1.2) on either the  $\alpha$ - or  $\beta$ -phenylhydrazone or the *p*-nitrophenylhydrazone, forms orange-yellow laminae, m. p. 218°, with previous softening and reddening; when suspended in 20% sodium hydroxide solution and treated with a little alcohol, it yields a deep violet solution, which is decolorised on dilution with water. T. H. P.

**Dioximes.** V. G. PONZIO and A. PICETTO (*Gazzetta*, 1923, 53, i, 20–24).—Of the two possible dioximes of triketohydrindene, only the 1:3-isomeride, obtained by the action of nitrous acid on  $\beta$ -hydrindone (Heusler and Schieffer, A., 1899, i, 365) is known. The 1:2-dioxime, being analogous structurally to benzoylmethylglyoxime (A., 1922, i, 1037), should be capable of existing in two modifications. The authors find that this 1:2-form may be readily obtained by adding sodium acetate and the theoretical quantity of hydroxylamine hydrochloride to a suspension of 2-oximino-1:3-diketohydrindene in hot alcohol and maintaining the mixture for some time at 60–70°. It exists, however, in only one form, which is neither dehydrogenated nor transformed into the corresponding oximino- $\psi$ -nitroketone-compound by the action of nitrogen tetroxide. It gradually decomposes with evolution of nitrous fumes and, like its phenylhydrazone, crystallises with a molecule of alcohol. Thus, it exhibits certain properties of nitroso-derivatives, but it may be acetylated and benzoyleated and in aqueous solution reacts with metallic nickel.

1:3-Diketohydrindene, for which improved conditions of preparation are given (cf. Wislicenus and Kötze, A., 1889, 1067), forms crystals of the tetragonal system [ZAMBONINI:  $a:c=1:0.984812$ ]; modified conditions are also given for making 2-oximino-1:3-diketohydrindene, which does not form a nickel salt, but when treated in aqueous-alcoholic solution with cobaltous acetate yields a cobaltic salt,  $(C_6H_4(C_2O_2(CNO)_3)_3Co$ , as a micro-crystalline, brownish-yellow powder, m. p. above 300° (decomp.). Thus, 2-oximino-1:3-diketohydrindene acts towards cobaltous salts like  $\alpha$ -benzilmonoxime, whereas other  $\alpha$ -oximinoketones yield cobaltous compounds.

*Triketohydrindene 1:2-dioxime*,  $\begin{array}{c} CO-C:NOH \\ | \\ C_6H_4-C:NOH \end{array}$ , crystallises in white or pale straw-coloured prisms, m. p. 168° (decomp.), containing  $1H_2O$ , which is lost slowly at the ordinary temperature. It dissolves in solutions of alkali hydroxide or ammonia, giving reddish-yellow solutions from which it is precipitated unchanged by the action of carbon dioxide or a dilute mineral acid. With hydroxylamine hydrochloride and sodium acetate, it yields the corresponding trioxime (cf. Wislicenus and Kötze, *loc. cit.*). The nickel compound,  $(C_6H_5O_2N_2)_2Ni$ , forms microscopic, pale yellowish-brown crystals, turning brown at 180°, m. p. above 300°. The

*diacetyl* derivative,  $C_{16}H_{16}O_5N_2$ , is somewhat unstable and forms pale straw-yellow needles, m. p.  $155^\circ$  (decomp.). The *dibenzoyl* derivative,  $C_{22}H_{14}O_5N_2$ , forms microscopic needles, m. p.  $174^\circ$  (decomp.). The *phenylhydrazone*,  $C_{15}H_{12}O_2N_4$ , EtOH, crystallises in orange-red needles, m. p.  $189-190^\circ$  (decomp.). T. H. P.

**Dioximes. VI.** G. PONZIO and L. AVOGADRO (*Gazzetta*, 1923, 53, i, 25-35).—The authors have investigated the two modifications of phenylglyoxime, m. p.  $168^\circ$  and  $180^\circ$ , regarded by Russanov (A., 1892, 321) as being the *amphi-* and *anti-*compounds, respectively, and have also obtained a second modification of aminophenylglyoxime. With such isomeric glyoximes, the prefix  $\alpha$  is given to those which readily undergo isomerisation into the other or  $\beta$ -forms, the latter alone being able to form with nickel, copper, or cobalt complex salts derived from two molecules of the glyoxime by replacement of two oximino hydrogen atoms, one from each molecule, by an atom of the bivalent metal. As might be foreseen from the results obtained with the benzoylmethylglyoximes (A., 1922, i, 1037), the two forms of phenylglyoxime behave differently towards nitrogen tetroxide, the  $\alpha$ -form losing two atoms of hydrogen and giving the compound regarded by Scholl (A., 1891, 315) as the peroxide,  $\begin{smallmatrix} O:N\cdot CH \\ | \\ O:N\cdot CPh \end{smallmatrix}$ , and by Wieland

and Semper (A., 1908, i, 108) as phenylfuroxan; the  $\beta$ -form, on the other hand, loses three atoms of hydrogen, one of which is replaced by a nitro-group, the resultant product being phenylnitro-glyoxime peroxide. These results confirm the view that the isomerism of the two phenylglyoximes does not depend on the relative positions of the hydroxyl groups in space.

The conclusion is drawn that  $\beta$ -phenylglyoxime and  $\beta$ -benzoylmethylglyoxime, which yield complex nickel salts, are true dioximes, as they behave towards nitrogen tetroxide as if they contain two similar oximino-groups, the resulting peroxides being unaffected by ammonia.  $\alpha$ -Phenylglyoxime, acetylmethylglyoxime, and  $\alpha$ -benzoylmethylglyoxime, which do not form complex nickel salts, react with nitrogen tetroxide, giving rise, respectively, to the compound  $C_6H_5\cdot C_2H_4O_2N_2$ , which with ammonia yields aminophenylglyoxime, to  $\alpha$ -oximino- $\beta$ - $\psi$ -nitrole- $\gamma$ -ketopentane, and to  $\gamma$ -oximino- $\beta$ - $\psi$ -nitrole- $\alpha$ -keto- $\alpha$ -phenylbutane (A., 1922, i, 627, 1037), which with ammonia yields aminomethylglyoxime. Hence the oximino-group of  $\alpha$ -phenylglyoxime, which is united to the carbon atom carrying the hydrogen atom and originates by the action of nitrous acid on acetophenone, may, like the  $\beta$ -oximino-group of acetylmethyl- or benzoylmethylglyoxime, resulting from the action of nitrous acid on acetyl- or benzoyl-acetone, assume a structure different from that of the oximino-group introduced into isonitrosoacetophenone, isonitrosoacetylacetone, or isonitrosobenzoylacetone by means of hydroxylamine.

The author's results show that Wieland and Semper (*loc. cit.*) are in error in assuming that the various modifications of one and the same dioxime give the same peroxide, even if, as follows from

the work of Korev (A., 1886, 363) and of Auwers and Meyer (A., 1889, 403, 713),  $\alpha$ -,  $\beta$ -, and  $\gamma$ -benzildioximes give the same peroxide when dehydrogenated by means of potassium ferricyanide.

Addition of aqueous nickel acetate to an aqueous alcoholic solution of  $\alpha$ -phenylglyoxime yields the amorphous, brownish-yellow nickel compound, probably  $C_8H_6O_2N_2Ni$ . With nitrogen tetroxide, the  $\alpha$ -glyoxime gives the compound  $C_8H_6O_2N_2$ , m. p.  $108^\circ$ , which is perfectly stable in a stoppered bottle in the dark (cf. Wieland and Semper, *loc. cit.*).

In aqueous solution,  $\beta$ -phenylglyoxime acts on compact nickel, copper, or cobalt, slowly in the cold but rapidly at about  $100^\circ$ , this behaviour being characteristic of the glyoximes which Tschugaev terms *syn*-forms. The nickel salt,  $(C_8H_6O_2N_2)_2Ni$ , crystallises in dark red needles, m. p.  $267^\circ$  (browning); the copper salt,  $(C_8H_6O_2N_2)_2Cu$ , forms a coffee-coloured powder with green reflection, m. p.  $181^\circ$  (decomp.), and the cobalt salt, a coffee-coloured powder with red reflection. Russanov's statement that  $\beta$ -phenylglyoxime is transformed instantaneously into the  $\alpha$ -form by all neutral solvents with the exception of absolute ether (*loc. cit.*) is erroneous. Nitrophenylglyoxime peroxide, obtained by the action of nitrogen tetroxide on  $\beta$ -phenylglyoxime in anhydrous ethereal solution, has the properties given by Wieland (A., 1903, i, 769), who found this compound among the products of the action of nitrous fumes on cinnamaldehyde.

*Chlorophenylglyoxime*,  $NOH:CPh\cdot CCl:NOH$ , prepared either by the action of hydroxylamine on chloro-oximinoacetophenone or by the action of chlorine on  $\alpha$ - or  $\beta$ -phenylglyoxime, exists in only one modification, and crystallises in slender, white needles, m. p.  $189-190^\circ$  (decomp.). Its nickel salt,  $(C_8H_6O_2N_2Cl)_2Ni$ , forms slender, reddish-brown needles, m. p.  $167^\circ$  (decomp.), and its diacetyl derivative,  $C_{12}H_{11}O_2N_2Cl$ , slender, white needles, m. p.  $82^\circ$ .

$\beta$ -Aminophenylglyoxime,  $NOH:CPh\cdot C(NH_2):NOH$ , obtained by boiling its  $\alpha$ -isomeride with dilute acetic acid, and isolated as nickel salt, forms lustrous, white laminae, m. p., with rapid heating,  $195^\circ$  (sublim. and decomp.), and yields an intense brown coloration with ferric chloride. Its nickel salt,  $(C_8H_6O_2N_3)_2Ni$ , forms lustrous, orange-red laminae, m. p.  $265-285^\circ$  (decomp.), and the copper salt,  $(C_8H_6O_2N_3)_2Cu$ , lustrous, bronze-coloured laminae with metallic lustre, m. p., with rapid heating,  $232^\circ$  (decomp.). T. H. P.

**The Transformation of Campholic Acid into Camphor.** H. RUPE and A. SULGER (*Helv. Chim. Acta*, 1923, 6, 259-263).—The benzylidenecampholic acid of Rupe and Blechschmidt,  $CO_2H\cdot C_8H_{14}\cdot CH:CHPh$  (A., 1918, i, 222), reacts with thionyl chloride to form an acid chloride, which, however, when it is distilled under reduced pressure changes with evolution of hydrogen chloride into benzylidenecamphor. The same transformation occurs spontaneously in the course of a few days when a solution of the acid chloride in thionyl chloride is kept. The chloride of benzylcampholic acid, however, is quite stable. The reaction in the case of benzylidenecamphoryl chloride probably takes place through

the intermediate formation of the compound  $C_8H_{14} \begin{smallmatrix} \text{CH} \cdot \text{CHClPh} \\ \text{CO} \end{smallmatrix}$ , which loses hydrogen chloride forming benzylidenecamphor. In the case of benzylcampholyl chloride, this reaction is, of course, impossible. The influence of ring-closure on optical rotatory power is here very marked, the value for benzylidenecampholic acid being  $[\alpha]_D^{20} + 12.60^\circ$ , and for benzylidenecamphor,  $[\alpha]_D^{20} + 426.55^\circ$ . Camphor derivatives also show a higher rotation dispersion than those of campholic acid. The supposed ethyl ester of benzylidenecampholic acid obtained by Rupe and Blechschmidt from the chloride (*loc. cit.*) is not the ester, but benzylidenecamphor.

E. H. R.

**Derivatives of Buchu-camphor.** YASUHIKO ASAHINA and SATORU KWADA (*J. Pharm. Soc. Japan*, 1923, 1—9; cf. Asahina and Mituhori, A., 1922, i, 667).—The formation of buchu-camphor from menthone by the action of ferric chloride was again studied; but the yield could not be increased beyond 24%. The m. p.,  $113^\circ$ , for the phenylurethane is confirmed (Semmler and Mackenzie, A., 1906, i, 373, gave  $41^\circ$ ). By boiling an alcoholic solution of hydroxylamine hydrochloride, sodium carbonate, and buchu-camphor on a water-bath for five hours under reflux, the monoxime, plates, was obtained, m. p.  $123^\circ$  (Semmler and Mackenzie, *loc. cit.*, give m. p.  $125^\circ$ , Kondakov, A., 1901, i, 334, gives  $156^\circ$ ); its alcoholic solution gave a green coloration with ferric chloride. When the boiling is continued for ten hours, the resulting oxime has m. p.  $154\text{--}157^\circ$ , and the analytical figures suggest that a dioxime is formed. When an alcoholic solution of buchu-camphor, hydroxylamine hydrochloride, and sodium acetate is heated at  $100^\circ$  in a sealed tube for ten hours, the true dioxime, colourless, short prisms, m. p.  $192^\circ$ , is formed; it gives a brownish-red coloration with ferric chloride. When oxidised with potassium permanganate in acetone solution, buchu-camphor is known to yield  $\gamma$ -acetyl- $\alpha$ -isopropylbutyric acid, but when the oxidation is conducted in 5% potassium hydroxide solution at about  $5^\circ$ , a diketonic acid,  $\text{COMe} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CHPr}^2 \cdot \text{CO} \cdot \text{CO}_2\text{H}$ , large, square plates, m. p.  $135^\circ$ , is produced, which, when distilled at  $190\text{--}195^\circ/11\text{ mm.}$ , or when heated with concentrated hydrochloric acid, is easily changed into the closed ketonic acid,  $\text{CH}_2 \begin{smallmatrix} \text{CO} \text{---} \text{CH} \\ \text{CH}_2 \cdot \text{CHPr}^2 \end{smallmatrix} \text{C} \cdot \text{CO}_2\text{H}$ , white plates, m. p.  $104^\circ$ . The semicarbazone, white crystals, m. p.  $223^\circ$ ; phenylhydrazone, slender, light yellow prisms, m. p.  $220\text{--}221^\circ$ ; and oxime, white granules, m. p.  $185\text{--}186^\circ$ , of the diketonic acid are identical with those obtained from the closed ketonic acid.

K. K.

**Effect of Fuller's Earth on Pinene and other Terpenes.** CHARLES S. VENABLE (*J. Amer. Chem. Soc.*, 1923, 45, 728—738).—The action of fuller's earth on  $\alpha$ -pinene and other terpenes, with and without diluents, at  $-20^\circ$ ,  $-5^\circ$ ,  $25^\circ$ , and  $153^\circ$  has been investigated.

In contrast to the conclusions of Gurvich (A., 1915, i, 933), the

reaction evidently proceeds as follows: (1) Intramolecular rearrangement to dipentene and terpinene. No camphene is formed. (2) Polymerisation to dipinene and various unidentified polyterpenes. (3) Slow decomposition of the polyterpenes at high temperatures to give paraffin hydrocarbons and *p*-cymene, but not monoterpenes. With increasing temperature of reaction, the proportion of dipinene and polyterpenes to terpenes increases.

Nopinene, dipentene,  $\alpha$ -limonene, terpinene, camphene, sabinene, terpineol, borneol, and cineol undergo similar reactions. *p*-Cymene is quite unaffected by treatment with fuller's earth.

The maximum activity of the fuller's earth is attained when it contains 5–8% of combined moisture (burning temperature about 400°). Oxygenated diluents exert a strong inhibiting action.

Iron gel, silica gel, or activated charcoal do not promote this reaction.

W. S. N.

**Pinenes.** H. PARISELLE (*Ann. Chim.*, 1923, [ix], 19, 119–135).—Previous work on  $\alpha$ - and  $\beta$ -pinenes is again described (cf. A., 1921, i, 575). The preparation of nitrosochlorides of pinene resulted in confirmation of Wallach's observations on the relation of yield to rotatory power, but it is pointed out that the presence of less active  $\beta$ -pinene may lead to inconsistent results. The nitrosochloride formed is always inactive, and the author suggests that  $\alpha$ -pinene consists of a mixture of active and inactive isomerides which are not capable of separation, the latter form yielding the derivative and being itself formed from the active variety. The action of dry hydrogen chloride on  $\beta$ -pinene yields isobornyl chloride, on  $\alpha$ -pinene (from Aleppo turpentine), a crystalline hydrochloride of m. p. 124–128° and  $[\alpha] +35.9^\circ$ , whilst from  $\alpha$ -pinene extracted from Bordeaux turpentine the corresponding product has m. p. 120–126° and  $[\alpha] -32.5^\circ$ . A method of calculating the optical activity of  $\alpha$ -pinene based on the optical purity of  $\beta$ -pinene is given.

H. J. E.

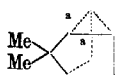

**The Wagner Rearrangement. II. The Formation of Santene.** L. RUTICKA and FR. LIEBL (*Helv. Chim. Acta*, 1923, 6, 267–281; cf. A., 1918, i, 398).—The expectation that by removal of water from  $\alpha$ -fenchocamphorol santene would be formed has been verified. By the action of phosphorus pentachloride on fenchyl alcohol in low-boiling light petroleum,  $\alpha$ -fenchone was obtained having  $[\alpha]_D -38^\circ$  instead of  $-32^\circ$ , as found by Wallach; its other constants were, b. p. 153–154°/720 mm.;  $n_D^{25} 1.4750$ ,  $d_4^{25} 0.870$ . It was oxidised with ozone to  $\alpha$ -fenchocamphorone, of which the semicarbazone gave two fractions from alcohol, a less soluble one having m. p. 217–218°,  $[\alpha]_D -171.5^\circ$ , and the more soluble one m. p. 210–211°,  $[\alpha]_D -141^\circ$ . The  $\alpha$ -fenchocamphorone regenerated from the total semicarbazone had, after sublimation, m. p. 107°. Thionyl chloride with fenchyl alcohol gives *fenchyl sulphite*,  $(C_{10}H_{17}O)_2SO$ , colourless crystals, m. p. 72°. The  $\alpha$ -fenchocamphorone was reduced with sodium and water to  $\alpha$ -fenchocamphorol, and the latter heated with potassium hydrogen sulphate at 190° in a stream of carbon dioxide, when santene distilled over, b. p.

140–142°,  $[\alpha]_D^{20}$  0,  $n_D^{20}$  1.4657,  $d_4^{20}$  0.8720. It was identified by oxidation with ozone to 1:3-diacetylcyclopentane. A mixture of  $\alpha$ - and  $\beta$ -fenchene was prepared by heating fenchyl alcohol with sodium hydrogen sulphate, and from this by the above method a mixed  $\alpha$ - and  $\beta$ -fenchocamphorol was obtained. When this was heated with potassium hydrogen sulphate as above, santene was obtained having practically the same constants as that from  $\alpha$ -fenchocamphorol. It is concluded that both  $\alpha$ - and  $\beta$ -fenchene give the same santene. From santanol, by heating with potassium hydrogen sulphate, santene was also obtained.

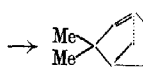

The authors' theory of the formation of an intermediate tricyclic in the course of the Wagner rearrangement (*loc. cit.*) has been rejected by Lipp (A., 1920, i, 491) and by Meerwein and Emster (A., 1920, i, 855), who have prepared the tricyclic and found it to be quite stable under the conditions of the borneol-camphene transformation. The alternative hypotheses suggested by these authors fail, however, to account for the formation of santene, whilst the tricyclic hypothesis offers a clear picture of the mechanism of the reaction. The simplest case is the formation of santene from santanol, when the intermediate tricyclic is represented by I. In the formation of santene from  $\alpha$ -fenchocamphorol,  $\beta$ -fenchocamphorol, and camphenilol, each of these compounds by loss of water can form the same tricyclic, represented by the space-formula II. By rupture of one of the bonds,  $a$ , a double-bond is formed attached to one of the bridge carbon atoms,

(I)

(II.) Tricyclicene.

(III.) Unstable.

(IV.) Santene.

an unstable configuration (III) which can only be stabilised by the wandering of one of the methyl groups, giving santene (IV). It has been urged as an objection to the tricyclic hypothesis that, since the tricyclic is symmetrical, it cannot give rise to an optically active product. This objection, however, can scarcely be maintained, since in the case of the transformation of optically active linalool into active terpineol, in the course of which the active centre is changed from one carbon atom to another, on any hypothesis, there must be a symmetrical intermediate stage. It must be supposed that, in the Wagner rearrangement, formation of the tricyclic and its isomerisation take place simultaneously, and that considerations which apply to the stable tricyclic do not apply to it in the nascent state.

E. H. R.

**$\beta$ -Amyrin from Manila Elemi Resin.** ALEX. ROLLETT (*Monatsh.*, 1923, 43, 413–417).—Alcoholic potassium hydroxide converts dibromo- $\beta$ -amyrin benzoate (A., 1921, i, 39; 1922, i, 667) into an impure potassium derivative, from which, on acidification, only a gelatinous substance is obtained. Bromination of  $\beta$ -amyrin in glacial acetic acid solution gives a mixture of (a) bromo- $\beta$ -amyrin

acetate, m. p. 235—236° (solution in concentrated sulphuric acid yellow, with green fluorescence), and (b)  *dibromo-β-amyrin*, m. p. 210—216° (decomp.). By oxidising β-amyrin with chromic acid, Vesterberg (A., 1892, 290) obtained β-amyrone (oxime, m. p. 262—263°). The latter substance, now called β-amyranone (oxime, m. p. 265—267°), melts at 177—179°. Potassium permanganate affords no isolable oxidation product with β-amyranone. The latter, on heating with benzoyl chloride, yields β-amyrenol benzoate, which melts at 181—182°, gives a yellow solution in concentrated sulphuric acid, and is converted by hot alcoholic potassium hydroxide into β-amyranone.

E. E. T.

**Constituents of Derris-root.** I. TATSUO KABIYONE and KENJIRO ATSUMI (*J. Pharm. Soc. Japan*, 1923, 10—17).—Greshoff (A., 1891, 335) and van Sillevoldt (A., 1900, i, 109) isolated an amorphous poisonous constituent, derrid, from the root of *Derris elliptica*, Benth., and Wray (*Pharm. J.*, 1892, 1152) obtained the constituent tubain. Ishikawa (A., 1918, i, 94) isolated tubotoxin,  $C_{18}H_{18}O_8$ , white crystals, m. p. 163.5°, from the root. The authors confirm Ishikawa's results. The poisonous constituent was proved to have one carbonyl group by the formation of a *phenylhydrazone*, light yellow needles, m. p. 255°, and an *oxime*, colourless needles, m. p. 245°. When heated with sodium acetate and acetic anhydride, tubotoxin gives a *diacetyl* derivative, the saponification value (84.3—116.9) of which is, however, lower than the calculated value (281.8). Estimation of methoxyl by Zeisel's or by Herzig's methods indicated the presence of 1.5-methoxyl groups in tubotoxin. Benzoyl chloride or phthalic anhydride have no action on it. Tubotoxin is probably identical with retelon obtained by Nagai (*J. Tokyo Chem. Soc.*, 1902, 23, 744) from *Millettia taiwaniana*, Hayata, produced in Formosa.

K. K.

**Bixin.** J. HERZIG and F. FALTIS [and, in part, BERTHA PITTMER, FRIEDRICH KLEIN, and GEORG WATZINGER] (*Annalen*, 1923, 431, 40—70; cf. A., 1917, i, 577).—Previous work on this subject, in particular the researches of Hasselt (A., 1911, i, 550; 1916, i, 495), and the facts described below, are discussed on the basis of the formula  $CO_2H \cdot C_{23}H_{26} \cdot CO_2Me$  for bixin, where  $C_{23}H_{26}$  is an unsaturated residue to which the carboxyl and carbomethoxyl groups are unsymmetrically attached.

Bixin, which cannot be esterified by means of alcoholic hydrogen chloride, absorbs eighteen atoms of hydrogen in glacial acetic acid suspension in the presence of palladium-barium sulphate, forming *hydrobixin*, a thick, almost colourless oil containing one methoxyl group, which can be esterified by means of methyl-alcoholic hydrogen chloride to *hydromethylbixin*, a thick, pale yellow oil, b. p. 280—285°/18 mm., containing two OMe groups, which is also produced when methylbixin absorbs eighteen atoms of hydrogen, and is hydrolysed by means of methyl-alcoholic potassium hydroxide to *hydronorbixin*, a thick oil, b. p. 220—230°/13 mm., which acts as a dibasic acid on titration; this may be reconverted into hydromethylbixin by means of diazomethane or 3% methyl-

alcoholic hydrogen chloride. When hydromethylbixin is hydrolysed by means of alcoholic potassium hydroxide and the product oxidised by means of potassium permanganate, six atoms of oxygen seem to be taken up; the resulting *yellow oil*, apparently  $C_{25}H_{40}O_6$ , contains no methoxyl group. It is readily methylated by means of 3% methyl-alcoholic hydrogen chloride to an *oil*,  $C_{27}H_{40}O_6$ , containing two methoxyl groups.

When hydronorbixin is heated at  $320^\circ$ , carbon dioxide is eliminated, but no definite product has been isolated. Nevertheless, by the action of heat on a mixture of lime and the *calcium* salt of hydronorbixin under reduced pressure, an *oil* is produced approximately of the composition  $C_{23}H_{46}$ ; the presence of two carboxyl groups in hydronorbixin is therefore probable.

The hydrolysis of methylbixin to norbixin by means of methyl-alcoholic sodium hydroxide is demonstrated. No pure compound is obtained by the esterification of norbixin by means of concentrated methyl-alcoholic hydrogen chloride; the use of diazomethane leads, however, to the formation of methylbixin and to a small quantity of an isomeride,  $\beta$ -*methylbixin*, dark violet crystals, m. p.  $190-193^\circ$ , which is the sole product if 3% methyl-alcoholic hydrogen chloride is used. It is also formed by the action of diazomethane in ethereal solution on  $\beta$ -*bixin*, minute, bordeaux-red crystals, decomp.  $211-214^\circ$ , an isomeride of bixin which has been obtained during the preparation of bixin from a sample from Dutch Orleans. The existence of three isomeric monomethyl esters, bixin,  $\beta$ -bixin, and isobixin (Hasselt, *loc. cit.*), cannot be ascribed merely to the unsymmetrical position of the carboxyl groups in the norbixin molecule. It is suggested that the wandering of a double bond may underlie the change of structure which obviously must accompany the production of at least one of these isomerides.

**New Pyrylium Salts.** C. GASTALDI and G. L. PEYRETH (*Gazzetta*, 1923, 53, i, 11-15).—Condensation of acetophenone or dypnone with propionic, butyric, and isovaleric anhydrides in presence of sublimed ferric chloride yields compounds analogous to that obtained under similar conditions from acetic anhydride (A., 1922, i, 573).

The *ferric chloride* compound of 4:6-diphenyl-2-ethylpyrylium chloride,  $FeCl_4 \cdot O \begin{smallmatrix} \text{C} \text{Et} \cdot \text{CH} \\ \text{CPh} \cdot \text{CH} \end{smallmatrix} \gg \text{CPh}$ , formed from propionic anhydride, forms long, yellowish-brown needles, m. p.  $167^\circ$ , and yields a pale yellow aqueous solution showing slight green fluorescence. When treated in aqueous solution with excess of ammonia, it yields 4:6-diphenyl-2-ethylpyridine, the *nitrate* of which,  $C_{19}H_{15}O_2N_2$ , forms slender, colourless needles, m. p.  $180^\circ$  (decomp.). 4:6-Diphenyl-2-ethylpyrylium *nitrate*,  $C_{19}H_{17}O_2N$ , crystallises in pale yellow laminae, m. p.  $151^\circ$  (decomp.).

The *ferric chloride* compound of 4:6-diphenyl-2-propylpyrylium chloride,  $C_{20}H_{19}O \cdot FeCl_4$ , formed from butyric anhydride, forms greenish-yellow plates, m. p.  $197-198^\circ$ , and dissolves in concen-

ated sulphuric acid with blue fluorescence. 4:6-Diphenyl-propylpyridine nitrate,  $C_{20}H_{20}O_3N_2$ , crystallises in colourless needles, m. p.  $138^\circ$  (decomp.).

The ferric chloride compound of 4:6-diphenyl-2-isobutylpyrylium chloride,  $C_{21}H_{21}O \cdot FeCl_4$ , forms yellow prisms, m. p.  $165^\circ$ , and gives a pale yellow, aqueous solution showing slight blue fluorescence; the nitrate,  $C_{21}H_{21}O_4N$ , forms yellow prisms, m. p.  $156^\circ$ . 4:6-Diphenyl-2-isobutylpyridine nitrate,  $C_{21}H_{22}O_3N_2$ , crystallises in colourless needles, m. p.  $124^\circ$ .

**A Synthesis of Pyrylium Salts of Anthocyanidin Type. II.**  
DAVID DOIG PRATT and ROBERT ROBINSON (T., 1923, 123, 745—58).

**A Direct Synthesis of certain Xanthylium Derivatives.**  
DAVID DOIG PRATT and ROBERT ROBINSON (T., 1923, 123, 739—45).

**Anhalonium Alkaloids. V. Synthesis of Anhalonidine and Pellotine.** ERNST SPÄTH (*Monatsh.*, 1923, 43, 477—484).—By the action of cold, concentrated hydrochloric acid on  $\beta$ -5-benzylxy-3:4-dimethoxyphenylethylamine (A., 1922, i, 852), the benzyl group is removed. Acetic anhydride converts the product into the *O,N*-diacetyl derivative, which, when heated in toluene solution with phosphoric oxide, gives a base which, from its mode of formation, must be either 6-acetoxy-7:8-dimethoxy- or 8-acetoxy-6:7-dimethoxy-1-methyl-3:4-dihydroisoquinoline, and on reduction with tin and hydrochloric acid gives a substance identical in all respects with anhalonidine. This alkaloid must therefore be either 6-hydroxy-7:8-dimethoxy- or 8-hydroxy-6:7-dimethoxy-1-methyl-1:2:3:4-tetrahydroisoquinoline. The former constitution accords the better with that of anhalamine, and is more probable on the grounds that the above ring-closure would be more likely to occur in the para-position to an acetoxy-group than in the similar position with respect to a methoxy-group.

By the addition of methyl iodide to the above dihydroisoquinoline derivative, and reduction of the product with tin and hydrochloric acid (the second process effecting also hydrolysis of the *O*-acetyl group), pellotine (i.e., *N*-methylanhalonidine) is obtained.

The great reactivity, with aldehydes, of the above-mentioned ethylamine derivative suggests that neither anhalonidine nor pellotine is formed in the plant as a result of enzyme action. The lability of groups attached to the asymmetric carbon atom in position 1, caused by the (probable) presence of a hydroxyl group in position 6, may explain the optical inactivity of the two natural alkaloids.  
E. E. T.

**Echinopsine.** ERNST SPÄTH and ALFRED KOLBE (*Monatsh.*, 1923, 43, 469—475).—This alkaloid, to which Greshoff (A., 1901, i, 338) erroneously assigned the formula  $C_{11}H_9ON$ , is identical with 1-methyl-4-quinolone,  $C_{10}H_9ON$ , obtained in an impure condition

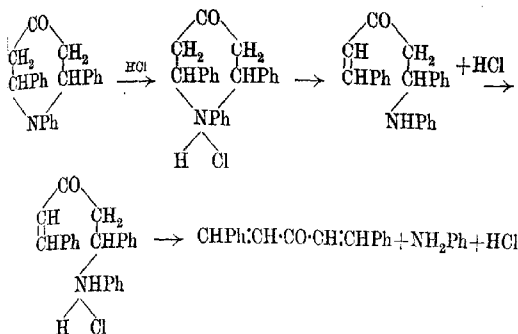

by Meyer (A., 1906, i, 604). On reduction, either with sodium and alcohol, or electrolytically, echinopsine is converted into 1-methyltetrahydroquinoline, whilst when heated with a mixture of phosphorus penta- and oxy-chlorides it is converted into 4-chloroquinoline. From the latter, quinoline is obtained by reducing with hydrogen in presence of palladium and barium sulphate. The alkaloid is readily obtained by heating 4-hydroxyquinoline with methyl iodide and sodium methoxide, and gives a *hydrochloride*, m. p. 185–186°, and a *picrate*, m. p. 223–224°. E. E. T.

**Preparation of Ergotamine Salts.** CHEMISCHE FABRIK VORN. SANDOZ (Brit. Pat. 170302).—Ergotamine salts are obtained in crystalline form by the action of the requisite amount of acid on the free base dissolved in an organic solvent miscible with water, such as methyl or ethyl alcohol, acetone, etc., whereby separation of the salt occurs almost immediately. The preparation of two sulphates in this way, containing 10.36% and 7.56%  $\text{H}_2\text{SO}_4$  respectively, is described. On recrystallisation, the former passes into the latter by loss of sulphuric acid. These and other ergotamine salts retain solvent of crystallisation very tenaciously. Salts containing a minimum amount of acid are obtained by shaking an ergotamine solution in a non-miscible organic solvent such as chloroform, with gradually increasing quantities of the acid. The precipitate is collected and recrystallised from methyl alcohol. In this way, a *hydrochloride* in the form of thin prisms containing, after drying to constant weight, 5.85%  $\text{HCl}$ , was obtained. The preparation of the tartrate in the form of compact prisms from ethyl alcohol, and of the citrate and carbonate in physiological sodium chloride solution, is also described. The ergotamine salts and their solutions are easily oxidised by air, particularly in sunlight, becoming thereby yellow or brown. Access of air should therefore be prevented during the preparation and storage of these compounds. G. F. M.

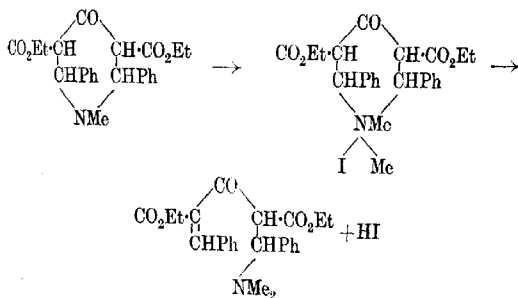

**Physostigmine. I. Alkylation Products of Eseroline.** GEORGE BARGER and EDGAR STEDMAN (T., 1923, 123, 758–769).

**Some Pyridine Derivatives of Iridium.** MARCEL DÉLÉPINE (*Ann. Chim.*, 1923, [ix], 19, 5–31).—A more detailed account of work already published (cf. A., 1922, i, 859; 1923, i, 89, 135, 243). H. J. E.

**A Reaction Involving the Rupture of the Ring in Heterocyclic Compounds. I.** P. PETRENKO-KRITSCHENKO, E. PUTIATA, and A. GANDELMAN (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1852–1861).—The action of hydrogen chloride and of methyl iodide on some substituted 4-piperidones is investigated. Hydrogen chloride is passed through a benzene solution of 1 : 2 : 6-triphenyl-4-piperidone. The hydrochloride thus precipitated is treated with alkali, which liberates distyryl ketone and aniline. This reaction is thus explained :

The case with which the ring is broken in this compound is due to the close proximity of the three phenyl groups, as the corresponding N-methyl compound when treated in the same way regenerates the same compound. It appears also that the triphenyl derivative can be stabilised by converting the grouping  $-\text{CH}_2\text{COCH}_2-$  into  $-\text{CHR}\cdot\text{CO}\cdot\text{CHR}-$ , where R is a carbethoxy-group. The action of methyl iodide on ethyl 2:6-diphenyl-1-methyl-4-piperidone-3:5-dicarboxylate is next examined. The hydriodide of this ester is prepared by the action of methyl iodide on the corresponding ester of diphenylpiperidonedicarboxylic acid, and the free 1-methyl ester, m. p.  $85^\circ$ , is obtained from it by the action of weak ammonia. Prolonged boiling of this substance with methyl iodide merely results in the formation of its hydriodide. The formation of this salt is explained as follows:

The hydrogen iodide thus liberated combines with unacted on 1-methyl ester to form its hydriodide. No other product was isolated from the reaction mixture. Hydrogen chloride passed through a benzene solution of this ester gives a variety of products, of which only one is identified as the stereoisomeride, m. p.  $138^\circ$ ,

of the original substance, m. p. 85°. The action of methyl iodide on *N*-methyltriacetoneamine is to cause rupture of the ring. The latter substance is preparable by the action of methyl iodide on triacetoneamine, thus showing that the view held up to the present, that the homologues of the latter substance cannot be prepared by direct alkylation, is incorrect.

R. T.

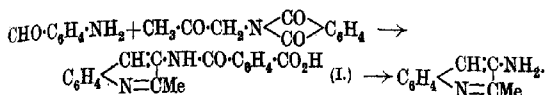

**Influence of Solvents on the Grignard Reactions.** RIKO MAJIMA and MUNIO KOTAKE (*J. Chem. Soc. Japan*, 1922, 43, 936-948; cf. this vol., i, 495).—The influence of solvents (ethyl ether and anisole) in the Grignard reaction between magnesium indole iodide and the following has been studied, with results which may be summarised as follows:

| Reagent.                     | Reaction products.            | Yields          |             |
|------------------------------|-------------------------------|-----------------|-------------|
|                              |                               | In ethyl ether. | In anisole. |
| Formic ester . .             | indole-2-aldehyde             | trace           | 33%         |
| Carbon dioxide . .           | indole-2-carboxylic acid      | 8.6%            | 25%         |
| Acetone . . . .              | 2-indolyldimethylmethane      | 22.5%           | 30.4%       |
| Benzaldehyde . .             | di-2-indolylphenylmethane     | 20%             | 61.6%       |
| Chloroformic ethyl ester . . | ethyl indole-2-carboxylate    | 53.5%           | 38.7%       |
| Acetyl chloride . .          | 2-indolyl methyl ketone       | 93%             | 61%         |
| Chloroacetyl chloride . .    | 2-indolyl chloromethyl ketone | 45%             | 4.8%        |

From the results, the authors have drawn the conclusion that when a compound having a carbonyl group acts on magnesium indole iodide, a good yield is obtained by using anisole as a solvent; whilst if the reacting compound is an acid chloride, ethyl ether is a better solvent.  $\beta$ -Indolylchloromethyl ketone forms colourless, rhombic crystals, m. p. 212–214°. K. K.

**3-Amino- and 3-Hydroxy-quinolines.** G. BARGELLINI and S. BERLINGOZZI (*Gazzetta*, 1923, 53, i, 3–11).—The authors have prepared 3-hydroxy-2-phenylquinoline by the action of *o*-aminobenzaldehyde on either *o*-bromoacetophenone or benzoylcarbinol, and 3-hydroxy-2-*p*-anisylquinoline from chloroacetanisole and *o*-aminobenzaldehyde, the action of ketones containing the group  $\cdot\text{CO}\cdot\text{CH}_2\text{X}$  (X=a halogen atom) on *o*-aminobenzaldehyde in presence of sodium hydroxide constituting a general method for the preparation of 3-hydroxyquinolines. Similar condensations occur if the *o*-aminobenzaldehyde is replaced by one of its derivatives or by isatin or an *o*-amino-ketone.

3-Aminoquinoline derivatives have been prepared by complicated series of reactions (Stark, A., 1907, i, 973; Mills and Watson, T., 1910, 97, 741), but no general method is known. The authors find that 3-amino-2-methylquinoline is readily prepared by condensing *o*-aminobenzaldehyde with acetonylphthalimide in presence of sodium hydroxide and decomposing the compound formed by boiling it with 20% hydrochloric acid:

3-Amino-2-phenylquinoline may be obtained similarly from *o*-aminobenzaldehyde and phenacylphthalimide. The formation of 3-nitroquinoline from *o*-aminobenzaldehyde and methazonic acid (Badische Anilin- & Soda-Fabrik, A., 1921, i, 517) is analogous to the method described above, since methazonic acid reacts as the oxime of nitroacetaldehyde.

The compound  $\text{C}_{18}\text{H}_{14}\text{O}_3\text{N}_2$  (formula I, above) forms silky, yellow needles, m. p.  $220^\circ$  (decomp.).

The compound  prepared from

*o*-aminobenzaldehyde and phenacylphthalimide, forms white scales, m. p.  $205-206^\circ$  (decomp.).

3-Amino-2-phenylquinoline,  $\text{C}_{17}\text{H}_{13}\text{N}_2$ , crystallises in pale yellow needles, m. p.  $115-116^\circ$ , and dissolves in acids, giving intensely fluorescent solutions. Its *acetyl* derivative forms colourless needles, m. p.  $173-175^\circ$ , and its *picrate*, yellow prisms, m. p.  $194-195^\circ$ .

3-Hydroxy-2-phenylquinoline,  $\text{C}_{16}\text{H}_{11}\text{ON}$ , prepared either by diazotisation of 3-amino-2-phenylquinoline or by the action of *o*-bromoacetophenone or benzoylcarbinol on *o*-aminobenzaldehyde (cf. Koenigs and Stockhausen, A., 1902, i, 693), forms white needles, m. p.  $221-222^\circ$ , and yields fluorescent aqueous and alcoholic solutions, the latter giving a reddish-brown coloration with ferric chloride. The *hydrochloride* forms lustrous, yellow scales, m. p.  $243-245^\circ$ ; the *chloroplatinate*, orange-yellow crystals, blackening above  $260^\circ$ ; the *picrate*, yellow prisms, m. p.  $235-238^\circ$  (decomp.); the *sulphate*, yellow leaflets, turning brown at  $150^\circ$  and melting indistinctly at about  $165^\circ$ .

3-Hydroxy-2-*p*-anisylquinoline,  $\text{C}_{16}\text{H}_{13}\text{O}_2\text{N}$ , crystallises in white needles, m. p.  $240-242^\circ$  (decomp.). The *sulphate*, yellow needles, m. p.  $225-230^\circ$  (decomp.), *hydrochloride*, *chloroplatinate*, and *picrate*, m. p.  $216-228^\circ$ , were prepared. T. H. P.

**$\gamma$ -Chloropropyl Urethanes and a Synthesis of the 1:3-Oxazine Ring.** ARTHUR W. DOX and LESTER YODER (*J. Amer. Chem. Soc.*, 1923, 45, 723-727).— $\gamma$ -Chloropropyl alcohol reacts readily with carbonyl chloride in ice-cold toluene solution to give  *$\gamma$ -chloropropyl chloroformate*, b. p.  $175-176^\circ/736$  mm., which, when heated with carbamide (2 mols.), gives  *$\gamma$ -chloropropyl allophanate*, white, scaly crystals, m. p.  $166^\circ$ .  *$\gamma$ -Chloropropyl carbamate*, white, pearly scales, m. p.  $62^\circ$ , is formed when  $\gamma$ -chloropropyl alcohol and carbamide nitrate (2 mols.) are heated together at  $130-135^\circ$ , or, in better yield (71%), when the chloroformate is slowly dropped into ice-cold 10% aqueous ammonia (2 mols.). Attempts to prepare an oxazine by the elimination of hydrogen chloride from the above carbamate were unsuccessful; the action of aqueous sodium hydroxide leads to hydrolysis, whilst with alcoholic sodium

ethoxide sodium cyanate and phenylcarbamide are produced.  $\gamma$ -Chloropropyl chloroformate reacts with aniline in ice-cold ethereal solution giving  $\gamma$ -chloropropyl phenylcarbamate, long, flat prisms, m. p.  $38^\circ$ , b. p.  $160$ — $170^\circ/5$  mm., which is also produced when chloropropyl alcohol and phenylcarbimide are gradually heated together at  $150^\circ$ ; the action of boiling aqueous-alcoholic sodium hydroxide on the carbanilate leads to 2-keto-3-phenyltetrahydro-1:3-oxazine, large, thick prisms, m. p.  $96^\circ$ , yield 84%. Chloropropyl chloroformate reacts in cold ethereal solution with o-toluidine to give  $\gamma$ -chloropropyl o-tolylcarbamate, small needles, m. p.  $49^\circ$ , b. p.  $170$ — $175^\circ/5$  mm., from which, by the elimination of hydrogen chloride, 2-keto-3-o-tolyltetrahydro-1:3-oxazine, large, flat prisms, m. p.  $89^\circ$ , is produced in 60% yield.

The formation of the 6-membered 1:3-oxazine ring is analogous to that of the 5-membered 1:3-oxazole ring, by the elimination of hydrogen chloride from  $\beta$ -halogen carbanilates (Otto, A., 1891, 1373; Johnson and Langley, A., 1910, i, 884). W. S. N.

**Tetrahydro-1:3:2-oxazones and Substituted  $\gamma$ -Aminopropanols.** J. S. PIERCE and ROGER ADAMS (*J. Amer. Chem. Soc.*, 1923, 45, 790—795; cf. this vol., i, 457).— $\gamma$ -Chloropropyl arylcarbamates are formed in aqueous suspension from aromatic amines and  $\gamma$ -chloropropyl chloroformate.  $\gamma$ -Chloropropyl arylcarbamates are converted by alcoholic potash (1 mol.) into tetrahydro-1:3:2-oxazones; if 4 mols. of alkali are used,  $\gamma$ -arylaminoopropanols are produced.

The following compounds are described:  $\gamma$ -Chloropropyl o-tolylcarbamate, white needles, m. p.  $46$ — $46.5^\circ$ , b. p.  $182.5^\circ/4.5$  mm.  $\gamma$ -Chloropropyl phenylcarbamate, white needles, m. p.  $35$ — $36^\circ$ , b. p.  $190^\circ/3.5$  mm.  $\gamma$ -Chloropropyl p-tolylcarbamate, b. p.  $188^\circ/4.5$  mm.  $\gamma$ -Chloropropyl o-chlorophenylcarbamate, b. p.  $178.5^\circ/3.5$  mm.  $\gamma$ -Chloropropyl p-chlorophenylcarbamate, white needles, m. p.  $53$ — $53.5^\circ$ , b. p.  $193^\circ/5$  mm.  $\gamma$ -Chloropropyl p-anisylcarbamate, white needles, m. p.  $63$ — $63.5^\circ$ , b. p.  $198.5^\circ/4$  mm.  $\gamma$ -Chloropropyl p-carboxyphenylcarbamate, white crystals, m. p.  $191$ — $192.5^\circ$ .  $\gamma$ -Chloropropyl  $\alpha$ -naphthylcarbamate, white needles, m. p.  $75.5$ — $76.5^\circ$ , b. p.  $206.5^\circ/4$  mm. 3-Phenyltetrahydro-1:3:2-oxazone, white plates, m. p.  $94$ — $94.5^\circ$ . 3-o-Tolyltetrahydro-1:3:2-oxazone, white prisms, m. p.  $87$ — $87.5^\circ$ . 3-p-Tolyltetrahydro-1:3:2-oxazone, white needles, m. p.  $127.5$ — $128^\circ$ . 3-o-Chlorophenyltetrahydro-1:3:2-oxazone, white cubes, m. p.  $99^\circ$ . 3-p-Chlorophenyltetrahydro-1:3:2-oxazone, white plates, m. p.  $111.5$ — $112^\circ$ . 3-p-Ethoxyphenyltetrahydro-1:3:2-oxazone, white plates, m. p.  $112.5$ — $113^\circ$ . 3-p-Carboxyphenyltetrahydro-1:3:2-oxazone, white plates, m. p.  $231$ — $232^\circ$ . 3- $\alpha$ -Naphthyltetrahydro-1:3:2-oxazone, white needles, m. p.  $149.5$ — $150.5^\circ$ .  $\gamma$ -Anilinopropyl alcohol, b. p.  $180.5^\circ/20.5$  mm. or  $154^\circ/5$  mm.  $\gamma$ -o-Toluidinopropyl alcohol, b. p.  $184^\circ/3$  mm.  $\gamma$ -p-Toluidinopropyl alcohol, b. p.  $163.5^\circ/3.5$  mm.  $\gamma$ -o-Chloroanilinopropyl alcohol, b. p.  $151.5^\circ/3.5$  mm.  $\gamma$ -p-Chloroanilinopropyl alcohol, b. p.  $167^\circ/3.5$  mm.  $\gamma$ -p-Phenetidinopropyl alcohol, white plates, m. p.  $42$ — $42.5^\circ$ , b. p.  $177^\circ/3.5$  mm.  $\gamma$ -p-Carboxyanilinopropyl alcohol, white

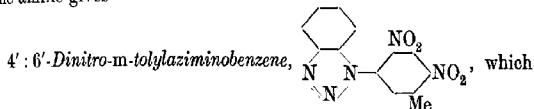

needles, m. p. 151—152°.  $\gamma$ - $\alpha$ -Naphthylaminopropyl alcohol, a yellow oil, b. p. 201.5°/3.5 mm. W. S. N.

**Reactions of Thiosemicarbazones. II. Action of Esters of  $\alpha$ -Halogenated Acids.** FORSYTH JAMES WILSON and ROBERT BURNS (T., 1923, 123, 799—804).

**The Action of Phenylenediamines on  $\beta$ - and  $\gamma$ -Trinitrotoluenes.** MICHELE GIUA and MARIO GIUA (*Gazzetta*, 1923, 53, i, 49—52).—4' : 6'-Dinitro-*m*-tolyl-*o*-phenylenediamine,

prepared by the interaction of 2 : 4 : 6-trinitrotoluene (1 mol.) and *o*-phenylenediamine (2 mols.) in alcoholic solution, crystallises in orange-yellow needles, m. p. 195—196°, dissolves in concentrated sulphuric acid with yellow coloration, and, in alcoholic solution, gives a deep red coloration with alkalis. With benzaldehyde it yields the *benzylideneimine*,  $\text{C}_{20}\text{H}_{16}\text{O}_4\text{N}_4$ , which forms lustrous, red prisms, m. p. 214—215°, and gives a red coloration with concentrated sulphuric acid. The *acetyl* derivative of the amine,  $\text{C}_{13}\text{H}_{14}\text{O}_5\text{N}_4$ , forms pale yellow prisms, m. p. 222—223°, and, in alcoholic solution, yields a red coloration with alkali. The action of nitrous acid on the amine gives

forms lustrous, white laminae, m. p. 164—165°, and, in alcoholic solution, gives a blue coloration with excess of alkali.

4' : 6'-Dinitro-*m*-tolyl-*m*-phenylenediamine,  $\text{C}_{13}\text{H}_{12}\text{O}_4\text{N}_4$ , prepared from 2 : 4 : 6-trinitrotoluene and *m*-phenylenediamine, crystallises in lustrous, reddish-yellow needles, m. p. 160—161°, gives a reddish-yellow solution in concentrated sulphuric acid, and, in alcoholic solution, gives a deep red coloration with alkali. Its *acetyl* derivative forms reddish-yellow prisms, m. p. 224—225°, and gives a dark red coloration with alkali in alcoholic solution.

4' : 6'-Dinitro-*m*-tolyl-*p*-phenylenediamine, obtained from 2 : 4 : 5-trinitrotoluene (1 mol.) and *p*-phenylenediamine, crystallises in long, garnet-red needles, m. p. 174—175°, yields a red solution in concentrated sulphuric acid, and, in alcoholic solution, forms a deep red coloration with alkali. The *acetyl* derivative separates in reddish-yellow, silky needles, m. p. 222—223°.

2' : 4'-Dinitro-*m*-tolyl-*o*-phenylenediamine, prepared from 2 : 3 : 4-trinitrotoluene and *o*-phenylenediamine, crystallises in lustrous, garnet-red needles, m. p. 149—150°, dissolves in concentrated sulphuric acid to a reddish-yellow solution, and, in alcoholic solution, gives a deep red coloration with alkali; it forms a pasty, golden-yellow *acetyl* compound. With benzaldehyde, it yields the *benzylideneimine*,  $\text{C}_{20}\text{H}_{16}\text{O}_4\text{N}_4$ , which forms lustrous, red prisms, m. p. 173—174°. With nitrous acid the amine gives

which crystallises in lustrous, white prisms, m. p. 156—157°, and, in alcoholic solution, gives with alkali a violet coloration changing immediately to blue.

2' : 4'-Dinitro-m-tolyl-p-phenylenediamine, prepared from 2 : 3 : 4-trinitrotoluene and p-phenylenediamine, crystallises in lustrous, garnet-red needles, m. p. 174—175°.

T. H. P.

**Application of the Hofmann Reaction to Substituted Carbamides.** GEORGE ROBERT ELLIOTT (T., 1923, 123, 804—813).

**The Action of Sodamide on Pyridine, with some Observations on 2-Aminopyridine and some of its Derivatives.** J. P. WIBAUT and ELISABETH DINGEMANSE (*Rec. trav. chim.*, 1923, 42, 240—250; *Proc. K. Akad. Wetensch. Amsterdam*, 1923, 25, 458—462; cf. Tschitschibabin and Zeide, A., 1915, i, 590).—The action of sodamide on pyridine results in formation of 2-aminopyridine, 4 : 4'-dipyridyl, and dipyridylamine, but 2 : 6-diaminopyridine and 4-aminopyridine were not detected. A study of the action of oxidising agents on 2-aminopyridine showed that it rapidly decolorises alkaline permanganate, has little action on alkaline chromate, and slowly reduces acid chromate solution. The oxidation products were not isolated.

2-Acetamidopyridine forms monoclinic prisms ( $a : b : c = 1.4939 : 1 : 2.0719$ ,  $\beta = 89^\circ 14' 30''$ ); 2-aminopyridylurethane crystallises in the monoclinic prismatic system ( $a : b : c = 0.7946 : 1 : 1.3552$ ,  $\beta = 73^\circ 21'$ ).

H. J. E.

**The Hydrolysis of the Xanthyl Derivatives of Veronal and Hypnotics of the Barbituric Acid Series, and its Importance in Toxicology.** RENÉ FABRE (*J. Pharm. Chim.*, 1923, [vii], 27, 337—339).—The xanthyl derivatives of veronal and other alkyl-barbituric acids, the preparation and use of which in toxicological investigations has previously been described (A., 1922, ii, 795), are readily hydrolysed by boiling for one hour with 20% alcoholic hydrogen chloride, and the original barbituric acid is recoverable from the reaction product in almost theoretical yield by rendering alkaline, extracting insoluble matter by means of ether, acidifying the alkaline solution, and extracting once more with ether. On evaporating the rather ethereal extract, the barbituric acid is obtained in pure crystalline form.

G. F. M.

**The Synthesis of Iminazolyglycine [Glyoxalineaminoacetic Acid]. The Lower Homologue of Histidine.** CORBET PAGE STEWART (*Biochem. J.*, 1923, 17, 130—133).—4(or 5)-Hydroxymethylglyoxaline, obtained from citric acid, was oxidised to the glyoxaline-4(or 5)-formaldehyde. The latter compound was converted by the treatment with potassium cyanide and ammonium chloride into the amino-nitrile, which was eventually hydrolysed to the amino-acid. The hydrochloride of the compound was found to be hygroscopic and decomposed when attempts were made to dry it at 100°. The picolonate, m. p. 243° (uncorr.), was prepared in order to purify the crude product obtained by the above method. Glyoxalineaminoacetic acid forms a condensation compound with

2:3:4-trinitrotoluene,  $\text{NH}\cdot\text{CH}=\text{C}\cdot\text{CH}\cdot\text{NH}\cdot\text{CO}_2\text{H}$  , the 3-nitro-group disappearing in the condensation; it forms deep yellow crystals, decomp. 270°. S. S. Z.

**Synthesis of Polypeptide Hydatoints. Tyrosyl-Alanine Hydatoint.** DOROTHY A. HAHN, LOUISE KELLEY, and FLORENCE SCHAEFFER (*J. Amer. Chem. Soc.*, 1923, 45, 843—857).—The alkylation of 4-*p*-anisylidenehydantoin and of 4-anisylhydantoin by means of ethyl  $\alpha$ -bromopropionate has been investigated; the ester group enters the position 3, in contrast to the behaviour of ethyl chloroacetate, which becomes attached to nitrogen in the position 1 (cf. A., 1916, i, 504; 1917, i, 475).

The action of sodium ethoxide and ethyl  $\alpha$ -bromopropionate on 4-*p*-anisylidenehydantoin leads to ethyl 4-*p*-anisylidenehydantoin-3- $\alpha$ -propionate, which exists in stereoisomeric forms, (a) large, glistening plates, m. p. 143°; (b) long, fine, white, felted needles, m. p. 176°; both forms of the ester are hydrolysed by means of hydrochloric acid, yielding corresponding forms of 4-*p*-anisylidenehydantoin-3- $\alpha$ -propionic acid,  $\text{NH}\cdot\text{CH}(\text{CO}\cdot\text{C}(\text{CH}_3)_2\cdot\text{CH}_2\cdot\text{OMe})\cdot\text{CH}(\text{CO}_2\text{H})\cdot\text{CH}_2\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$ , (a) hard, white needles or plates, m. p. 245°; (b) hard, white needles or plates, m. p. 269°. Either form of the ester, preferably the less fusible modification, is reduced by means of sodium amalgam in alcoholic solution to ethyl 4-*p*-methoxybenzylhydantoin-3- $\alpha$ -propionate, long, fine, white needles, or plates, m. p. 138°, which is also produced by the action of sodium ethoxide and ethyl  $\alpha$ -bromopropionate on 4-*p*-methoxybenzylhydantoin. This ester is converted by the action of alcoholic sodium hydroxide into the sodium salt, crystalline, of 4-*p*-methoxybenzylhydantoin-3- $\alpha$ -propionic acid, hard, white prisms, m. p. 164—166°, which is also formed by the action of concentrated hydrochloric acid on *N*-carbamyl-5-*p*-methoxyphenyl- $\alpha$ -iminodipropionic acid,

$\text{CO}_2\text{H}\cdot\text{CHMe}\cdot\text{N}(\text{CO}\cdot\text{NH}_2)\cdot\text{CH}(\text{CO}_2\text{H})\cdot\text{CH}_2\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$ , glistening, white plates, m. p. 148—149°, decomp. The latter is formed as its disodium salt, m. p. 240°, decomp., by the action of ethyl-alcoholic sodium ethoxide (2 mols.) on ethyl 4-*p*-methoxybenzylhydantoin-3- $\alpha$ -propionate. 4-*p*-Hydroxybenzylhydantoin-3- $\alpha$ -propionic acid, rosettes of hard, compact crystals, m. p. 217°, ethyl ester, long, felted needles, m. p. 192°, is formed by the action of hydriodic acid and red phosphorus at 100—110° on either form of 4-*p*-anisylidenehydantoin-3- $\alpha$ -propionic acid, either form of its ethyl ester, 4-*p*-methoxybenzylhydantoin-3- $\alpha$ -propionic acid, or its ethyl ester. When 4-*p*-hydroxybenzylhydantoin-3- $\alpha$ -propionic acid is heated for four hours at 155° with concentrated hydrochloric acid, it is converted into 4-methylhydantoin-3- $\alpha$ -*p*-hydroxyphenylpropionic acid,  $\text{NH}\cdot\text{CH}(\text{CO}\cdot\text{CHMe})\cdot\text{CH}(\text{CH}_2\cdot\text{C}_6\text{H}_4\cdot\text{OH})\cdot\text{CO}_2\text{H}$ , m. p. 221°, by an intramolecular rearrangement, probably involving the addition and subsequent elimination of the elements of water. The action

of concentrated hydriodic acid and red phosphorus at 180° or 4-*p*-hydroxybenzylhydantoin-3- $\alpha$ -propionic acid leads to a crystal line substance, m. p. 184°, of the probable formula,

and ammonia; the production of ammonia in this experiment, and the interconversions described, are clear proof that the propionic residue enters in the position 3 during the original alkylations.

W. S. N.

**Fluorindinium Salts.** F. KEHRMANN and PETER LEUZINGER (*Helv. Chim. Acta*, 1923, 6, 239—248).—By the action of methyl sulphate on diphenylphenofluorindine bases (cf. A., 1896, i, 512), basic dyes are formed, which are stable to alkalis and have the properties of ammonium salts. A number of such

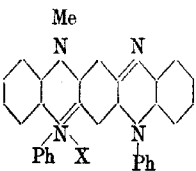

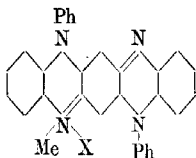

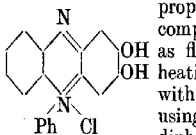

compounds have been prepared and characterised as fluorindinium salts. It was found that, by heating hydroxyaposafranone (annexed formula), with *o*-aminodiphenylamine or its hydrochloride, using benzoic acid as solvent, only the green isodiphenylphenofluorindine was formed, unaccom-

panied by the red diphenylphenofluorindine. The constitution of

diphenylmethylphenofluorindinium monoacid salts is expressed by the accompanying formula, where X is the acid radicle. *Diphenylmethylphenofluorindinium perchlorate*,  $\text{C}_{31}\text{H}_{23}\text{O}_4\text{N}_4\text{Cl}$ , crystallises in bronze needles, and the *di-perchlorate* forms bright, brassy needles. Both are practically insoluble in water, but soluble in boiling 80—90% alcohol.

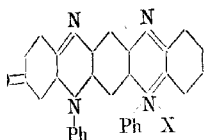

The colour in concentrated sulphuric acid is greenish-blue with a strong red fluorescence, not changing on dilution, but becoming pure blue when the free acid is neutralised. Cold alkali hydroxide does not change the colour of the alcoholic solution, but on warming the colour becomes reddish-violet with a fiery red fluorescence, through hydrolysis of the methyl group. Aqueous solutions of phenofluorindinium salts have an intensely bitter taste, whilst salts of diphenylphenofluorindine are tasteless. Ethyl sulphate reacts more slowly than methyl sulphate with diphenylphenofluorindine in nitrobenzene solution. *Diphenylethylphenofluorindinium diperchlorate* resembles the lower methyl homologue; the reactions are similar but decomposition of the ammonium base by alkali is considerably slower.

The constitution of salts of isodiphenylmethylphenofluorindinium may be expressed by the annexed formula, although alternatives are possible. *isoDiphenylmethyl(ethyl)phenofluorindinium mono- and di-perchlorates* resemble closely the isomeride described above. When the bases are warmed with alkali in alcoholic solution, an olive-green colour quickly develops, but this green is not due to formation of

isodiphenylphenofluorindine, since it slowly changes to a reddish-violet with a strong red fluorescence. The nature of these changes is not yet been determined.

When isodiphenylphenofluorindine is oxidised with chromic acid, the reaction cannot be stopped at the di-phenazonium stage, but proceeds to the formation of a fluorindinone, corresponding closely with the oxidation of phenylphenazonium salts to aposafranone by

air. *isoDiphenylphenofluorindinone perchlorate*, annexed formula,  $C_{30}H_{19}O_3N_4Cl$ , forms small, green needles with a brassy reflex, dissolving in 80% alcohol with a permanganate-red colour, unaltered by ammonia or carbonate, but changing to orange-yellow with sodium hydroxide.

In concentrated sulphuric acid it has yellowish-green colour, becoming violet-red on dilution. When reduced in alcohol with stannous chloride, it becomes intensely bluish-green, probably due to the formation of a *hydroxyisodiphenylphenofluorindine* salt. This is reoxidised by ferric chloride. The perchlorate forms fairly large brassy crystals, and the *chloroplatinate*,  $(C_{30}H_{19}ON_4)_2PtCl_6$ , a heavy, greenish-grey, metallic, microcrystalline powder.

E. H. R.

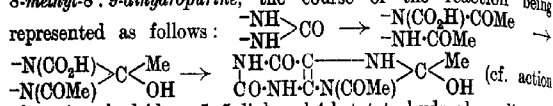

**Solubility of Uric Acid in Water.** HEINRICH BILTZ and ESBET HERBERMANN (*Annalen*, 1923, 431, 104—111).—It is shown that the supersaturation which occurs (cf. A., 1921, i, 606, 609; also Chad and Boden, A., 1913, i, 403) when a warm aqueous solution of uric acid is allowed to cool to room temperature in contact with solid uric acid is probably the cause of the high values for the solubility found by Bensch (*Annalen*, 1845, 54, 190) and Behrend and Roosen (*Annalen*, 1889, 251, 250). A true equilibrium is, however, slowly reached when a cooled supersaturated solution is shaken, or, more rapidly, when solution is effected by shaking the solid acid with water at the room temperature; the values for the solubility found in this way agree with the figures of His and Paul (A., 1901, i, 131; cf. Kohler, A., 1911, i, 690). The observation of His and Paul, that the solubility increases with the time of shaking, has not been confirmed, but it is agreed that saturation is quickly attained.

In these experiments, solution is effected in vessels of Jena glass, the concentrations being determined by evaporation of the filtered liquid in a platinum dish. After weighing, the basin and contents are brought to a red heat, cooled, and re-weighed, to determine the soluble matter present in the solution, derived from the glass. Incidentally, the stability of uric acid and of 3:9-dimethyluric acid to water is demonstrated by means of measurements of hydrogen-ion concentration.

W. S. N.

**Action of Acetic Anhydride on Uric Acid.** HEINRICH BILTZ and WALTER SCHMIDT (*Annalen*, 1923, 431, 70—104).—During the preparation of 8-methylxanthine by the action of acetic anhydride on uric acid (A., 1902, i, 125), Boehringer & Söhne isolated an intermediate product (A., 1902, i, 504) which they described as

2:4-dioxy-5:6-diacetamidopyrimidine; this could undoubtedly give 8-methylxanthine by elimination of acetic acid. Since, however, only one acetyl group can be eliminated by hydrolysis, it is now suggested that this intermediate product, the preparation of which is described, is to be formulated as 9-acetyl-2:6:8-trioxy-8-methyl-8:9-dihydropurine, the course of the reaction being represented as follows:

of acetic anhydride on 5:5-diphenyl-4-ketotetrahydroglyoxaline, A., 1922, i, 871). If ring formation occurs before the elimination of the carboxyl group, the process is comparable with the formation of carbinols from orthodiamines (Fischer, A., 1901, i, 413; 1902, i, 188). It is shown that the formula also agrees with the other properties of the substance.

Hydrolysis by means of aqueous sodium hydroxide or of fuming hydriodic acid leads to 2:6:8-trioxy-8-methyl-8:9-dihydropurine, which forms tabular prisms, decomp. above 300°, and yields an amorphous silver salt, a perchlorate, decomp. 163—164°, a sulphate, hydrochloride, and nitrate, and also a potassium salt, ciliate needles, which reacts with benzoyl chloride, giving a benzoyl derivative (? benzoate), very small leaflets of high melting point. Trioxymethyldihydropurine gives alloxan when oxidised by means of chlorine water. Trioxymethyldihydropurine, or its acetyl derivative, when heated with acetic anhydride loses water, or acetic acid, with formation of 8-methylxanthine, identical with Boehringer & Söhne's product, after the latter has been purified (details given) through the potassium salt; the perchlorate, colourless, tabular crystals, decomp. 292—294°, hydriodide, large, tabular crystals, sulphate, long, slender, four-sided prisms, mononitrate, small crystals, and the dinitrate, slender needles, are described. The reduction of trioxymethyldihydropurine by means of hydriodic acid, or, as a side-reaction, the hydrolysis of the acetyl derivative by the same reagent, leads to 8-methyl-8:9-dihydroxanthine, small, colourless, transparent leaflets of high melting point, hydriodide, small, glistening six-sided tablets, decomp. indefinitely.

The methylation of trioxymethyldihydropurine by means of methyl sulphate leads to 2:6:8-trioxy-3:8-dimethyl-8:9-dihydropurine, long, slender needles, decomp. 305—306°, in which the second methyl group is attached to nitrogen, since no methoxyl is removable by means of hydriodic acid. That the methyl group is in position 1 or 3 is shown by the production, when oxidised with chlorine water, of a product which gives methylvioluric acid monohydrate on treatment with hydroxylamine acetate. The structure of the above dimethyl compound is finally proved by the production, by the action of acetic anhydride and a little pyridine, of 3:8-dimethylxanthine (A., 1902, i, 125), the constitution of which is now fixed beyond doubt by its synthesis from acetic anhydride and a sample of 3-methyluric acid (A., 1919, i, 292, 293) absolutely free from 9-methyluric acid.

2:4-Dioxy-5:6-diaminopyrimidine (Traube, A., 1900, i, 389), the preparation of which is described, gives a *sodium* salt, small, faintly yellowish-brown leaflets, which with hydrochloric acid gives a *hydrochloride*, pale yellow crystals, decomp. 253—255°; a *nitrate* has also been prepared. The action of acetic anhydride and a little pyridine on the above sodium salt leads to 2:6:8-trioxy-1:9-diacetyl-8-methyl-8:9-dihydropurine, small, brown prisms of high melting point, probably identical with the product described by Boehringer & Söhne (*loc. cit.*) as triacetyldiaminouracil; the *monohydrate* of a *sodium* salt of the same compound, slender needles, decomp. 258—260°, is also formed. The latter gives the 9-acetyl derivative on partial hydrolysis by means of sodium hydroxide; both the diacetyl compound and the sodium salt give trioxymethyl-dihydropurine on prolonged alkaline hydrolysis. W. S. N.

**Reactions of Diazonium Salts with Cupric Compounds. I.**  
A. CONTARDI (*Ann. Chim. Appl.*, 1923, 7, 13—28).—Previous work on the transformations of diazo-compounds, especially those effected with the help of cupric salts, is discussed, and a table is given showing, for forty different amino-derivatives, the compounds obtained when the corresponding diazo-salts are treated with cupric chloride (or bromide) or sodium or cupric nitrite, and also those obtained when the diazophenols are treated with cupric chloride or bromide. Considerations of these results leads to the following generalisations: (1) In monohalogenated and mononitroanilines replacement of the amino-group by a nitro-group proceeds regularly and, usually, with almost theoretical yields; exceptions are *m*-nitro-aniline, which gives a poor yield of *m*-dinitrobenzene, and certain compounds of analogous structure. (2) The amino-group in a monohalogenated nitroaniline or in a dinitroaniline may be replaced by a nitro-group by passing through the diazo-compound only when the new nitro-group enters in such a position that its elimination and replacement by an amino-group by heating with alcoholic ammonia is possible; Fry's theory, according to which the eliminability of nitro-groups depends on their polarity, is discussed. (3) Halogen atoms introduced into the benzene nucleus exert comparatively little influence on these transformations, which, however, they may render impossible if they occupy the 2-, 4-, or 6-position with respect to the amino-group; in other cases, however, they facilitate the changes or render them practicable to some degree. (4) It has not yet been found possible to introduce a new nitro-group into trinitro-substituted amines by diazotisation. (5) During the substitution of the amino-group by the nitro-group, certain aromatic amines, especially those containing no strongly electro-negative substituent elements or groups in the nucleus, are converted into the corresponding mononitrophenols. T. H. P.

**Liquid Crystals of Anisylidene-*p*-aminoazotoluene. P.**  
GAUBERT (*Compt. rend.*, 1923, 176, 907—909).—Polemical. The author maintains the accuracy of his observations on the isotropic forms of anisylidene-*p*-aminoazotoluene, which have been disputed by Friedel (*this vol.*, ii, 223). G. F. M.

**Existence of an Unidentified Sulphur Grouping in the Protein Molecule. I. On the Denaturation of Proteins.** LESLIE J. HARRIS (*Proc. Roy. Soc.*, 1923, [B], 94, 426-441).—It has been found that, whereas crystalline egg-albumin does not give the sodium nitroprusside reaction, a strongly positive reaction is given with the denatured protein. It is suggested that the denaturation of proteins involves the setting free of a reactive group, probably sulphydrol. It is considered probable that in heat coagulation of proteins a chemical change into metaprotein first takes place, followed by a physical change into the coagulated protein.

W. O. K.

**Existence of an Unidentified Sulphur Grouping in the Protein Molecule. II. On the Estimation of Cystine in certain Proteins.** LESLIE J. HARRIS (*Proc. Roy. Soc.*, 1923, [B], 94, 441-450).—Cystine is estimated by hydrolysis of the protein and isolation of the cystine under standard conditions. The actual amount found is estimated multiplied by 100/39.53, this factor being based on the amount of cystine isolated after hydrolysis, from gelatin to which a definite amount of pure cystine had been added. Whereas, in serum-albumin, the cystine accounts for no less than 89% of the total sulphur content, in ovalbumin 86% of the sulphur still remains to be accounted for.

W. O. K.

**The Action of Sodium Chloride on Collargol.** A. F. GERASIMOV (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1848-1851).—It is shown that if a collargol solution is coagulated by acetic acid, and a sodium chloride solution slowly added, the coagulated silver at first redissolves and then, as the concentration of sodium chloride increases, is reprecipitated. This phenomenon is explained by the adsorption law, according to which adsorption is a function of ionic concentration. It is assumed that at low concentrations, chloridion is more adsorbed than natrion, whilst at higher concentrations the reverse is the case. Thus, in the former case, a preponderating quantity of negatively charged chloridions is adsorbed by the discharged particles of silver, which thus acquire a negative charge, and once again go into solution. When, however, the concentration of sodium chloride rises beyond a certain point, more natrions are adsorbed on the particles than chloridions, and their negative charge is again neutralised, causing them to be reprecipitated.

R. T.

**Autoclave Hydrolysis of Proteins with Carbon Dioxide and Oxalic Acid.** V. S. SADIKOV (*Biochem. Z.*, 1923, 136, 238-240).—Egg-albumin and goose feathers were hydrolysed by aqueous solutions of carbon dioxide under pressure in an autoclave at 160-185°. The biuret reaction was negative. Gelatin and casein under similar conditions with oxalic acid gave products soluble in alcohol which do not give the biuret or ninhydrin reaction. The results are preliminary.

H. K.

**Products of the Catalytic Fission of Proteins.** V. S. SADIKOV and N. D. ZELINSKY (*Biochem. Z.*, 1923, 136, 241-249).—This

aper is a description of results obtained for which the experimental details and methods of separation are promised later. ix kg. of goose feathers were hydrolysed in an autoclave at 180° with 1% hydrochloric acid for six hours. The product does not give the biuret reaction. It was extracted successively with ether, ethyl acetate, chloroform, and amyl alcohol, which accounted for 90% of the material. The ethereal extract contained crystalline anhydrides, a number of which have been identified, and a syrupy mixture of anhydrides. The ethyl acetate contained crystalline and syrupy anhydrides and free amino-acids. The chloroform extract contained syrupy and crystalline anhydrides. The amyl-alcoholic extract contained anhydrides and free amino-acids. The aqueous liquor left after extraction with solvents contains simple and complex amino-acids and also nitrogen-free acids. H. K.

**Determination of the Rate of Digestion of Albumin.** A. FRIEDERICH (*Chem. Ztg.*, 1923, 47, 265—266).—The increase of concentration of soluble albumin taking place during the process of digestion with pepsin is measured by means of Löwe's interferometer (*ibid.*, 1921, 45, 405, 1025), which admits of a high degree of accuracy. 2.5 Grams of the substance under examination are placed in a 250 c.c. flask together with 150—200 c.c. of water and 10 c.c. of dilute hydrochloric acid. The mixture is incubated at 37° and repeatedly shaken until the interferometer readings of two samples filtered off at intervals of one hour are the same, showing that all soluble albumin has gone into solution. 0.5 Gram of pepsin is then added and the volume in the flask made up to the mark with water at 37°. The contents are shaken and 1 c.c. is filtered off and its interferometer reading taken as the zero reading of the solution. The contents of the flask are incubated at 37° and small samples withdrawn and filtered every hour and their interferometer readings taken until these readings remain constant. A larger quantity of the solution is then filtered and the soluble albumin in the clear filtrate estimated by a micro-Kjeldahl method. This gives the total digestible albumin present, and enables the interferometer readings to be transposed into terms of percentage of albumin digested. The method gives consistent results. The data from two specimen analyses and curves showing the rate of digestion in each case are given. One sample was completely digested in two hours, whilst the other required twenty-seven hours. The percentages of digestible albumin present were 82.6 and 67.6, respectively. Other methods only showed a trifling difference between these two samples. H. C. R.

**Conphaseolin. A New Globulin from the Navy Bean, *Phaseolus vulgaris*.** HENRY C. WATERMAN, CARL O. JOHNS, and D. BREESE JONES [with S. PHILLIPS] (*J. Biol. Chem.*, 1923, 55, 93—104).—In addition to the globulins phaseolin and phaselin isolated by Osborne (A., 1896, i, 454; 1897, i, 207), the navy bean contains a third globulin, *conphaseolin*. This has been isolated by fractional precipitation of a sodium chloride extract of the bean with ammonium sulphate. Conphaseolin resembles the  $\alpha$ -globulins

obtained from other beans of the genus *Phaseolus* (cf. for example, A., 1922, i, 1101), and is distinguished from phaseolin and phaseclin by its high sulphur content. Analysis by Van Slyke's method gave the following values for basic amino-acids: Cystine 1.18%, arginine 6.87%, histidine 0.85%, lysine 10.69%. Phaseclin has been similarly analysed, with the following results (cf. A., 1920, i, 401): cystine 1.16%, arginine 6.36%, histidine 2.36%, lysine 9.42%.

E. S.

**Chlorinated Proteins.** E. SALKOWSKI (*Biochem. Z.*, 1923, 136, 169—189).—Albumose and casein have been chlorinated. Chloro-casein on hydrolysis yields the same products as casein with fewer reducing substances. It is very resistant to pepsin and trypsin, and shows little tendency to putrefy.

H. K.

**The Optical Properties of Leguminates of the Alkali Metals.** M. A. RAKUZIN and G. F. PEKARSKAJA (*J. Russ. Phys. Chem. Soc.*, 1916, 48, 1888—1889).—Various optically active alkali metal leguminates have been prepared, and their optical rotations measured: the ammonium salt has  $[\alpha]_D -67.33^\circ$ , the lithium salt,  $[\alpha]_D -38.66^\circ$ , the sodium salt,  $[\alpha]_D -39.31^\circ$ , and the potassium salt,  $[\alpha]_D -39.62^\circ$ . The low values obtained for the last three salts are undoubtedly due to racemisation, but a gradual increase in the optical rotation is observable with increasing atomic weight of the metal. R. T.

**Crystals of Hæmoglobin of Rodents, particularly of the Hamster (German Marmot).** OTTO KRUMMACHER (*Z. Biol.*, 1923, 77, 175—180).—Crystals of hæmoglobin prepared from the blood of a hamster have been found to belong to the monoclinic system. Those obtained from most other mammals are rhombic, except those from the squirrel, which are hexagonal. Those from the pigeon are quadratic.

W. O. K.

**The Effect of Carbon Dioxide and Acetic Acid on the Osmotic Pressure of Hæmoglobin.** HELENE CONNET WILSON (*Biochem. J.*, 1923, 17, 59—71).—The osmotic pressure of solutions of purified hæmoglobin is three or four times as great when dialysed against acetic acid or water saturated with carbon dioxide (both about  $P_H 4$ ) as against water alone. The author is of the opinion that this phenomenon is due to the ionisation of some salt of hæmoglobin such as the one which ionises into protein-ions, or into protein- and acetate-, or protein- and bicarbonate-ions.

S. S. Z.

**Preparation and Estimation of Guanylic Acid: the Solubility of Sodium Guanylate in Salt Solutions and Water.** R. FEULGEN and H. ROSSENBECK (*Z. physiol. Chem.*, 1923, 125, 284—288).—The solubility of sodium guanylate in solutions of sodium acetate and of sodium chloride has been determined, with reference to the isolation of guanylic acid as the sodium salt by Feulgen's method, which depends on the relative insolubility of that acid in sodium acetate solution (A., 1921, i, 136). W. O. K.

**Keratin. III.** A. HEIDUSCHKA and E. KOMM (*Z. physiol. Chem.*, 1923, 126, 130—142; cf. this vol., i, 69).—By the use of

the iron method of Siegfried, a peptone has been isolated from the products of the partial hydrolysis of horn (cf. *loc. cit.*), having the empirical formula  $C_{11}H_{20}O_5N_3$  and  $[\alpha]_D^{20} -15.5^\circ$  approx.

W. O. K.

**A New Synthesis of *r*-Tryptophan.** RIKO MAJIMA and MUNIO KOTAKE (*J. Chem. Soc. Japan*, 1922, 43, 926–936).—*r*-Tryptophan has been synthesised from indole. Alessandri (A., 1915, i, 988) failed to obtain  $\beta$ -indolealdehyde,  $C_8H_7N\cdot CHO$ , from magnesium indole halide and formic ester using ether as a solvent, whilst the authors have succeeded in obtaining the aldehyde by the same method using anisole as a solvent, the yield being 40%. When phenetole was used instead of anisole, the yield decreased to about 23%, and when ethyl ether, amyl ether, or dimethylaniline were used, the aldehyde was not obtained. Using ethoxymethyleneaniline instead of formic ester, the aldehyde was also obtained, but the yield was less and the product was impure.  $\beta$ -Indolehydanitoin,  $C_8H_7N\cdot CH\cdot C_3H_2O_2N_2$ , is formed by heating  $\beta$ -indolealdehyde and hydanitoin with anhydrous sodium acetate and acetic anhydride at  $106$ – $108^\circ$  during thirty minutes; the product was boiled with alcohol and filtered after cooling and the residue dissolved into *N*-sodium hydroxide solution, precipitated by acidifying the solution with acetic acid, and crystallised from glacial acetic acid, the yield being 46.6%.  $\beta$ -Indolehydanitoin is reduced by sodium amalgam in sodium hydroxide solution to *o*-hydanitoylskatole,  $C_8H_7N\cdot CH_2\cdot C_3H_3O_2N_2$  (yield 68%), which is then decomposed into *r*-tryptophan,  $C_8H_7N\cdot CH_2\cdot CH(NH_2)\cdot CO_2H$ , by heating with saturated baryta water at  $108^\circ$  for six hours, the yield being 53%. The product forms long, hexagonal plates with silky lustre, and decomposes at  $283$ – $285^\circ$ . As a by-product, an unknown compound,  $C_{12}H_{13}O_3N_3$ , crystallising in plates, m. p.  $207^\circ$  (decomp.), is obtained.

K. K.

**Apparatus for Preparing Dry Powders of Dissolved or Suspended Thermolabile Substances.** DAG SALOMONSON and H. VON EULER (*Arkiv Kem. Min. Geol.*, 1922, 8, No. 24, 1–3).—The loss of activity of enzyme solutions by alcohol precipitation may be diminished by concentrating at low temperatures and pressures before precipitating. Dry preparations of enzymes are readily obtained by using a modified form of Krause's apparatus (D.R.P. 297388 of 1918). The solution or suspension to be evaporated is blown by means of carbon dioxide from a capillary jet surrounded by a slightly wider one through which the same gas is blown, warm carbon dioxide ( $70^\circ$ ) being blown through a third jet enclosing the other two. The jets pass into a large glass cylinder, the other end of which is covered with silk. The dry material collects in the cylinder. Air may be used for evaporating yeast solutions by this method, but for enzymes carbon dioxide is essential, to prevent oxidation.

E. E. T.

**Nomenclature of Proteases.** CARL OPPENHEIMER (*Biochem. Z.*, 1923, 136, 140–141).—The proteases can be provisionally

classified as follows. A. *True proteases* which break down protein to the peptide stage. These include *pepsinases*, characterised by an optimum in acid solution, *trypsinases* with an optimum zone near neutrality. B. *Peptidases* or *creptases* which only split peptides or peptones.

H. K.

**Saccharase.** H. VON EULER and KARL JOSEPHSON (*Arkiv Kem. Min. Geol.*, 1922, 8, No. 23, 1-9).—The amino-nitrogen present in saccharase has been estimated by Van Slyke's methods (A., 1916, ii, 61). About two-thirds of the total nitrogen present is apparently in ring-combination. The following figures are given for the complete analysis of saccharase: ash 1-4, phosphorus 1-2, hexoses 60-20, pentoses under 5, total nitrogen 5-8, amino-nitrogen 2, easily-eliminable nitrogen about 1 per cent. These figures do not seem to be at variance with the suggestion that saccharase contains nucleic acid groupings (cf. A., 1922, i, 959), although the absence of positive tests for pentoses makes it improbable that Levene's type of nucleotide groupings is present. It is thought that combination between saccharase and sucrose is more likely to be due to partial valency addition than to adsorption.

The irreversible inactivation of saccharase by iodine (cf. A., 1922, i, 1076) has been further studied. It is now found that saccharase, cinnamic acid, benzaldehyde, and alanine behave similarly in not combining with or adsorbing iodine in dilute aqueous solutions. Bromine, under similar conditions, is taken up by saccharase, 1 g. of which combines with or adsorbs 0.48 g. of bromine. Cinnamic acid combines with 1 molecular proportion of bromine in like circumstances, alanine reacts with bromine in amounts depending on time, whilst benzaldehyde scarcely reacts at all. The authors therefore refrain from discussing the presence of definite groupings in the saccharase molecule.

E. E. T.

**Inactivation of Saccharase by *p*-Phenylenediamine, *p*-Toluidine, and Formaldehyde.** H. VON EULER and KARL MYRBÄCK (*Z. physiol. Chem.*, 1923, 125, 297-314).—*p*-Phenylenediamine and *p*-toluidine inhibit the action of saccharase (invertase), the former being the more effective if they are applied in molecular proportions. The action of *p*-phenylenediamine decreases with increase in the concentration of the substrate and is minimal at a  $P_H$  of about 3.5. Similar effects are obtained with *p*-toluidine, the exact effect of the hydrogen-ion concentration depending on the amount of the inhibitor added. Preliminary incubation of enzyme and inhibitor before addition of sugar appears to have little effect, whereas the inhibiting effect of formaldehyde is increased by such incubation. Diphenylphosphoric acid also inhibits the action of invertase, an effect which decreases with increasing acidity.

W. O. K.

**Purification of Yeast-saccharase.** KARL JOSEPHSON (*Arkiv Kem. Min. Geol.*, 1922, 8, No. 26, 1-21).—An examination of the methods used by Willstätter and Racke (A., 1922, i, 598) for the

preparation of saccharase. It is found that bottom-yeast is better for this purpose than top-yeast, presumably because it is freer from yeast-gum. Purification is effected by the following series of processes: autolysis in presence of 10% of toluene and 1% of ethyl acetate; filtration; precipitation with alcohol; dissolution in water and adsorption on aluminium hydroxide, using as small a volume as possible; elution, using potassium dihydrogen phosphate and sucrose solution; and dialysis through collodion membranes (Euler and Svanberg, A., 1920, i, 689). Kaolin then removes yeast-gum, by adsorption, as stated by Willstätter and Racke, and affords very active saccharase. A second adsorption on aluminium hydroxide, followed by elution, gives a still more active product, whereas a second kaolin adsorption effects no improvement. Adsorption on cupric hydroxide apparently causes complete loss of activity, whilst sugar-charcoal adsorbs neither saccharase nor the accompanying substances. For further work, see Euler and Josephson (this vol., i, 402).  
E. E. T.

### Poisoning of Starch Amylase; Starch Liquefaction. III.

URBAN OLSSON (*Z. physiol. Chem.*, 1923, 126, 29—99).—A comparison of the effect of copper sulphate, iodine, and aniline on the liquefaction of starch and on the production of sugar from it by malt diastase shows that the decrease in activity in the first two cases is quantitatively parallel, whilst in the case of aniline the liquefactive power is practically unaffected, although the sugar-producing power is decreased up to 21%. The method previously described (A., 1922, ii, 401) is adapted to quantitative measurement of the liquefactive power. It is found that the amount of sugar corresponds with a unimolecular reaction, whilst the liquefactive power is proportional to the amount of enzyme.

The effect of silver nitrate on maltase is proportional to the amount of the salt present, except with comparatively large amounts, when the decrease in activity lessens in proportion to the amount of silver nitrate present.  
W. O. K.

### The Reversibility of the Ferment Action of $\alpha$ -*D*-Mannosidase.

H. HÉRISSEY (*Compt. rend.*, 1923, 176, 779—782).—The action of  $\alpha$ -*D*-mannosidase is reversible, and according to the composition of the medium in which it is working it can bring about either the hydrolysis of a *D*-mannoside to mannose, or the synthesis of the mannoside from mannose. In a medium consisting of 10% methyl alcohol and about 1% of either mannose or  $\alpha$ -*D*-methylmannoside, in identical position of equilibrium is eventually reached in each case which corresponds with 46—47% of the methylmannoside.

G. F. M.

**Urease. I. The Chemical Changes Involved in the Zymolysis of Urea.** WILLIAM ROBERT FEARON (*Biochem. J.*, 1923, 17, 84—93).—Cyanic acid has been isolated as the silver salt from solutions of urea undergoing decomposition by urease. It is suggested that urease acts as a dissociating enzyme which decomposes the neutral urea molecule into ammonia and cyanio

acid; the latter is further decomposed by the solvent into ammonia and carbon dioxide. The cyanic acid attains a maximum concentration in the urea-urease system and is being produced as fast as it is hydrolysed. The decomposition of urea through the medium of the enzyme proceeds similarly to the normal decomposition of urea by acids, alkalis, and heat.

S. S. Z.

**Vitamins.** H. VON EULER and ALLAN BERNTON (*Arkiv Kem. Min. Geol.*, 1922, 8, No. 21, 1—9).—Continuing previous work (A., 1908, ii, 724), the authors have isolated from carrots a *phosphatide*,  $C_{48}H_{88}O_{13}N$  (or  $N_2$ )P, and a *sterol*,  $C_{25}H_{44}O$ , m. p. 142°. The latter substance causes no appreciable increase in the fermentation of dextrose by bottom-yeast (freed from co-enzyme by previous washing and drying) in presence of sodium phosphate at  $p_H$  4.5. The fermentation of dextrose by a similar yeast is unaffected by sodium pyruvate in presence of sodium phosphate at  $p_H$  5 (cf. Neuberg, A., 1915, i, 1045).

E. E. T.

**Additive Reactions of Phosphorus Halides. VII. Addition of Alkyl- and Aryl-alkoxy-chlorophosphines to Carbonyl Compounds.** J. B. CONANT, V. H. WALLINGFORD, and S. S. GANDHEKER (*J. Amer. Chem. Soc.*, 1923, 45, 762—768).—A continuation of previous work (A., 1918, i, 74; 1920, i, 454; 1921, i, 69; 1923, i, 69, 186) dealing with the 1:2 and 1:4 addition of phosphorus trichloride and its aryl derivatives.

Benzaldehyde condenses at the ordinary temperature, in the presence of acetic acid, with phenoxydichlorophosphine, methoxydichlorophosphine, and ethoxydichlorophosphine, forming, respectively, the *phenyl*, *methyl*, and *ethyl* esters of  $\alpha$ -hydroxybenzylphosphinic acid,  $OH\cdot CHPh\cdot PO(OH)\cdot OR$ , as oils; the constitution of these esters is proved by the production of  $\alpha$ -hydroxybenzylphosphinic acid on hydrolysis by means of 15% aqueous hydrochloric acid, the free acid being readily identified as its aniline salt.

Phenoxydichlorophosphine condenses with phenyl styryl ketone in the presence of acetic acid, or, better, acetic anhydride, with formation of phenyl  $\beta$ -benzoyl- $\alpha$ -phenylethylphosphinate.

In the presence of acetic acid, diphenoxychlorophosphine undergoes the following condensations: with benzaldehyde, to form *diphenyl  $\alpha$ -hydroxybenzylphosphinate*, m. p. 146°, identified by hydrolysis to the acid; with acetone, to form *diphenyl  $\alpha$ -hydroxyisopropylphosphinate*, m. p. 113—114°, *acetate*, m. p. 72—72.5°; with methyl ethyl ketone, to form *diphenyl  $\alpha$ -hydroxyisobutylphosphinate*, m. p. 128.5°; with acetophenone, to form *diphenyl  $\alpha$ -hydroxy- $\alpha$ -methylbenzylphosphinate*, white cubes, m. p. 143.5°. *Diphenyl  $\alpha$ -hydroxy- $\beta$ -chloroisopropylphosphinate*, white cubes, m. p. 119°, is formed from chloroacetone and diphenoxychlorophosphine in the presence of benzoic acid, but those substances do not condense in the presence of acetic acid.

The diphenoxychlorophosphine used in these experiments is prepared by heating phosphorus trichloride (0.5 mol.) with triphenylphosphite (1 mol.) for six hours at 150°; the yield is 90% of theory.

W. S. N.

**Organic Arsenic Derivatives.** HEINRICH WIELAND (*Annalen*, 923, 431, 30–40).—[With A. KULENKAMPFF.]—The direct introduction of arsenic into the benzene nucleus (cf. Michaelis and Tabinerson, A., 1892, 1321) is accomplished by the addition of aluminium chloride (2.5 mols.) to a boiling solution of arsenic trichloride (1 mol.) in a large excess of benzene. Since aromatic arsenic derivatives are decomposed by aluminium chloride, 30–0% of the total arsenic present is converted into the free element; the remainder appears as phenylarsine dichloride (5 parts), diphenylarsine chloride (1 part), and triphenylarsine (14 parts). [With W. LADELUNG.]—Triphenylarsine is also obtained in 60% yield by the gradual addition of diphenylarsinic acid (26 g.) to warm phenylhydrazine (11 g.); the suggested mechanism of this reaction is indicated by the following equations: (1)  $\text{AsPh}_2\text{O}\cdot\text{OH} + \text{NH}_2\cdot\text{NHPh} = \text{AsPh}_2\cdot\text{OH} + \text{C}_6\text{H}_6 + \text{N}_2 + \text{H}_2\text{O}$ . (2)  $\text{AsPh}_2\cdot\text{OH} + \text{NH}_2\cdot\text{NHPh} = \text{AsPh}_2\cdot\text{NH}\cdot\text{NHPh} + \text{H}_2\text{O}$ . (3)  $\text{AsPh}_2\cdot\text{NH}\cdot\text{NHPh} + \text{AsPh}_2\text{O}\cdot\text{OH} = \text{AsPh}_2\cdot\text{N}\cdot\text{NPh} + \text{AsPh}_2\cdot\text{OH} + \text{H}_2\text{O}$ . (4)  $\text{AsPh}_2\cdot\text{N}\cdot\text{NPh} = \text{Ph}_3\text{As} + \text{N}_2$ . If phenylarsinic acid is used, the reaction proceeds less readily, whilst arsenic acid is merely reduced to arsenious acid.

[With A. BLOEMER.]—When acetylene is led into a cooled mixture of aluminium chloride and arsenic trichloride, addition of the latter to the triple bond of the acetylene occurs (cf. A., 1922, i, 1033), with formation of *β-chlorovinylarsine dichloride*, a colourless oil, b. p. 7–78°/12 mm., which reacts with a second molecule of acetylene to give *di-β-chlorovinylarsine chloride*, a heavy, colourless oil, b. p. 13°/11 mm., previously described by Dufert (*Monatsh.*, 1919, 40, 13) as a molecular compound. This secondary arsine chloride combines with a further molecule of acetylene, forming *tri-β-chlorovinylarsine*, a colourless oil, b. p. 138°/12 mm., m. p. 13°. All three compounds appear in the product. The tertiary arsine is apparently not attacked by dilute hydrogen peroxide, but the secondary and primary arsine chlorides are readily oxidised to *di-β-chlorovinylarsinic acid*, long, glistening prisms, m. p. 122°, and *β-chlorovinylarsinic acid*, long, glistening plates, m. p. 129°, respectively, both of which are decomposed by concentrated alkali hydroxide into acetylene, hydrogen chloride, and arsenic acid.

[With H. WESCHE.]—*Cacodyl carbide*, a golden-yellow oil, b. p. 45°/14 mm., has been prepared by the gradual addition of cacodyl chloride to a suspension of magnesium acetylene bromide in boiling ether; the substance is highly unsaturated, explodes in contact with nitric acid, and is reconverted by alkali into acetylene, with elimination of the arsine radicle. W. S. N.

**Arsenated Benzanilide and its Derivatives.** W. LEE LEWIS and C. S. HAMILTON (*J. Amer. Chem. Soc.*, 1923, 45, 757–762).—The arsenated benzanilides are prepared by the action of *p*-dichloroarsinbenzoyl chloride (1 mol.) on aromatic amines in benzene solution. The impure product, which still contains chlorine united to the arsenic, is isolated as the arsenic acid after oxidation in glacial acetic acid solution by means of 3% hydrogen peroxide solution. The addition of sodium halide to the acetic acid solution gives the

corresponding dihalide, whilst the arsino-derivatives are best prepared by reduction by means of phosphorous acid or hypophosphorous acid in hot concentrated alcoholic solution.

The following arsino-compounds,  $\text{AsO}_3\text{H}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{NHR}$ , form colourless crystals of high melting point: *p*-Arsinobenzanilide, *p*-arsinobenzanthranilide, *p*-arsinobenzo-*p*-anisidide, *p*-arsinobenzo-*p*-phenetidide, and *p*-arsinobenzo-*o*-anisidide. *p*-Arsinobenzoyl-arsanilide,  $\text{AsO}_3\text{H}_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{AsO}_3\text{H}_2$ , is formed by the oxidation, by means of alkaline hydrogen peroxide, of hydrated *p*-arsinosobenzoylarsanilide,  $\text{As}(\text{OH})_2\cdot\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{AsO}_3\text{H}_2$ , produced by the condensation of arsanilic acid with *p*-dichloroarsinebenzoyl chloride. The following arseno-compounds,  $\text{As}_2(\text{C}_6\text{H}_4\cdot\text{CO}\cdot\text{NHR})_2$ ,

are yellow, insoluble, and of high melting point. *p*-Arsenobenzanilide, *p*-arsenobenzanthranilide, *p*-arsenobenzo-*p*-anisidide, *p*-arsenobenzo-*p*-phenetidide, *p*-arsenobenzo-*p*-xylylidide, *p*-arsenobenzo- $\alpha$ -naphthylidide. The following halogen derivatives are described: *p*-di-iodoarsinebenzo-*p*-anisidide, yellow needles, m. p. 209—210°, *p*-di-iodoarsinebenzo-*p*-phenetidide, yellow needles, m. p. 227—228°; *p*-di-iodoarsinebenzethylanilide, canary-yellow needles, m. p. 115—116°, *p*-di-iodoarsinebenzo-*o*-anisidide, m. p. 148—149°, *p*-dibromoarsinebenzo-*o*-anisidide, slightly yellow crystals, m. p. 167—168°, *p*-dichloroarsinebenzo-*o*-anisidide, slightly yellow crystals, m. p. 164—165°, *p*-dichloroarsinebenzethylanilide, colourless cubes, m. p. 147—148°.

Gluconic acid condenses rapidly with *p*-arsanilic acid in hot methyl-alcoholic solution to form *gluconyl-p*-arsanilic acid,  $\text{OH}\cdot\text{CH}_2\cdot[\text{CH}\cdot\text{OH}]_4\cdot\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{AsO}_3\text{H}_2$ , and more slowly in cold methyl-alcoholic solution with 3:4-diaminophenylarsinic acid to form 3:4-di(gluconylamino)phenylarsinic acid, yield 70%; both these acids are readily hydrolysed by means of dilute alkali.

W. S. N.

**Arsination of *o*-Cresol and *m*-Cresol.** WALTER G. CHRISTENSEN (*J. Amer. Chem. Soc.*, 1923, 45, 800—804).—In the arsination of *o*-cresol the formation of tar is much greater, the yield less, and the isolation of the products more difficult than in the case of phenol (Jacobs and Heidelberger, A., 1919, i, 604); the arsination of *m*-cresol proceeds with less formation of tar.

The action of arsenic acid on *o*-cresol at 155—160° leads to 6-hydroxy-*m*-tolylarsinic acid, 6:6'-dihydroxydi-*m*-tolylarsinic acid, 2-hydroxy-*m*-tolylarsinic acid, m. p. 198—200°, and 2:6'-dihydroxydi-*m*-tolylarsinic acid, m. p. 208—210°; the last two acids give a purple coloration with ferric chloride.

The action of arsenic acid on *m*-cresol at 140—146° leads to 5-hydroxy-*o*-tolylarsinic acid, 3-hydroxy-*o*-tolylarsinic or 3-hydroxy-*p*-tolylarsinic acid, m. p. 165—167°, giving a red coloration with ferric chloride. Secondary arsinic acids are also produced, which are not, however, completely separable, although a partial separation is effected by fractional decomposition of the calcium salts.

W. S. N.

**Preparation of *p*-Tolyl Mercury Compounds.** FRANK C. WHITMORE, FRANCES H. HAMILTON, and NEAL THURMAN (*J. Amer. Chem. Soc.*, 1923, 45, 1066—1068).—The preparation of sodium toluene-*p*-sulphinat from toluene-*p*-sulphonyl chloride and zinc dust in aqueous suspension is described in an improved form, the yield being 80—90%. Sodium toluene-*p*-sulphinat and mercuric chloride react in boiling aqueous solution to give mercury *p*-tolyl chloride, yield 58%, which is converted into mercury di-*p*-tolyl by means of sodium iodide in boiling alcoholic solution, yield 80% (cf. Kharasch and Chalkley, A., 1921, i, 377). W. S. N.

**Reactions of Organic Mercury Compounds with Halides.**  
**I. Mercury Di-*p*-tolyl and Sulphonyl Halides.** FRANK C. WHITMORE and NEAL THURMAN (*J. Amer. Chem. Soc.*, 1923, 45, 1068—1071; cf. preceding abstract).—Toluene-*p*-sulphonyl iodide reacts with mercury di-*p*-tolyl, in boiling carbon tetrachloride solution, to give di-*p*-tolylsulphone, mercuric iodide, and tolyl-mercuric iodide; toluene-*p*-sulphonyl chloride does not react under the same conditions, but this chloride or benzenesulphonyl chloride reacts with mercury di-*p*-tolyl at higher temperatures in toluene or xylene solution, giving, however, only traces of definite organic products. No mercury phenyl chloride is obtained by the action of benzenesulphonyl chloride on mercury di-*p*-tolyl. W. S. N.

## Physiological Chemistry.

**The Anticatalytic Action of Hydrocyanic Acid.** OTTO WARBURG (*Biochem. Z.*, 1923, 136, 266—277).—In opposition to Wieland's theory of cell respiration, but in support of the author's theory that cell respiration is catalysed by a surface effect of the heavy metals contained in living cells, experiments are detailed. Hydrocyanic acid in minute amounts inhibits the oxidation of leucine and oxalic acid by blood charcoal, but if the charcoal be heated with concentrated hydrochloric acid to diminish its content of iron, it still oxidises leucine and oxalic acid, but hydrocyanic acid has less inhibiting action. Hydrocyanic acid inhibits by attachment to the heavy metals and prevents the activation of oxygen. H. K.

**Observations on the Effect of High Altitude on the Physiological Processes of the Human Body, Carried Out in the Peruvian Andes.** JOSEPH BARCROFT and OTHERS (*Phil. Trans.*, 1923, [B], 211, 351—480).—The chief result obtained by the expedition is that the lungs do not secrete oxygen. The pressure of oxygen in the blood was so nearly the same as that in the alveolar air that the passage of the gas through the pulmonary epithelium can only be attributed to diffusion. The increased concentration of corpuscles at high altitudes is not merely to transport a certain quantity of

oxygen; it also brings about an extra degree of buffering of the blood, allowing of a more alkaline corpuscle at a given carbon dioxide pressure of 25 mm., a higher dissociation curve, and therefore a corpuscle which is more acquisitive of oxygen in the lung.  
G. E.

**The Respiratory Exchange, Blood-reaction, and Level of Phosphoric Acid in the Blood During Mental Work.** HUGO WILHELM KNIPPING (*Z. Biol.*, 1922, 77, 165—174).—Mental work is accompanied by only small increases in heat production. Nevertheless, on the commencement of such work, there is an immediate rise in the respiratory quotient which then rapidly decreases to a value below that found at rest. From analyses of the phosphoric acid content of the blood before and during mental activity, it is concluded that this effect is due to the entrance of free phosphoric acid into the blood with the consequent liberation of carbon dioxide.  
E. S.

**The Immediate Effect of Heavy Exercise (Stair-running) on some Phases of Circulation and Respiration in Normal Individuals. I. Oxygen and Carbon Dioxide Content of Blood Drawn from the Cubital Vein Before and After Exercise.** CHRISTEN LUNDGAARD and EGGERT MÖLLER (*J. Biol. Chem.*, 1923, 55, 315—321).—Heavy exercise, in which the muscles of the arm were not used, produced, in sixteen out of seventeen cases investigated, a marked decrease in the oxygen content of blood taken from the cubital vein. In one case, no change was observed. Variations in carbon dioxide were small and irregular. Possible explanations are discussed.  
E. S.

**The Inorganic Phosphorus Content of the Blood of Normal Children.** GRACE HAY ANDERSON (*Biochem. J.*, 1923, 17, 43—48).—The inorganic phosphorus content of the whole blood of twenty-four normal children between three months and thirteen years ranges from 4—6.6 mg. per 100 c.c. The average came to 4.9 mg. It is advisable to use whole blood for the estimation of phosphorus, as a considerable error may be obtained if serum is used which has been in contact with clot for some time. Twenty-four hours of fasting and a recent ingestion of a diet rich in phosphorus made no difference to the inorganic phosphorus content of the blood. The Bell-Doisy method for the estimation of phosphorus which was employed was found to have a range of experimental error of not more than plus or minus 10%.  
S. S. Z.

**The Calcium Content of the Blood during Pregnancy.** SYBIL TAITE WIDDOWS (*Biochem. J.*, 1923, 17, 34—40).—The calcium metabolism during pregnancy is so well balanced that the blood maintains a constant value in spite of varying demands made on it by the fetus during this period. Even in the later stages of pregnancy, when these demands are high, no diminution in the calcium content of the blood is observed.  
S. S. Z.

**Carbohydrate Metabolism. I. Some Comparisons of Blood-sugar Concentrations in Venous Blood and in Finger Blood. II. An Interpretation of the Blood-sugar Phenomena following the Ingestion of Dextrose.** G. L. FOSTER (*J. Biol. Chem.*, 1923, 55, 291—301, 303—314).—I. Preliminary experiments indicated that the sugar concentration of arterial blood is identical with that of blood drawn from the finger tip. Hence the latter was used in place of arterial blood for the purpose of comparing the concentrations of sugar in venous and arterial blood during periods of active sugar absorption. The results show that, in the fasting condition, the concentrations are identical. After ingestion of dextrose or starch, the initial rise in concentration is much greater in finger than in venous blood; the subsequent hypoglycæmia is, moreover, much less marked in the case of finger blood. Ingestion of levulose is followed by a slight rise in the sugar concentration of both finger and venous blood, that in the latter being sometimes practically absent; apparently levulose is much more completely absorbed by the liver than dextrose. No marked hypoglycæmia was observed in the case of levulose. Galactose causes a much higher level of hyperglycæmia than dextrose, the values for venous and finger blood being similar. This agrees with the fact that galactose is a poor glycogen former. Contrary to the results of Cammidge, Forsyth, and Howard (A., 1922, i, 81), the ingestion of a non-carbohydrate (agar-agar) meal produced no change in blood-sugar. II. Experiments are reported which support the conclusion of McLean and de Wesselow (*Quart. J. Med.*, 1921, 14, 103) that glycogen formation is stimulated by a rise in blood sugar, thus preventing excessive hyperglycæmia after the ingestion of dextrose. Further, the subsequent hypoglycæmia is due to over-activity of the glycogen-forming mechanism. E. S.

**Blood Gas Analysis. XIII. Influence of  $\alpha$ -Rays on Hæmoglobin and Blood-corpuscles. II.** STRAUB and KL. GOLLWITZER-MEIER (*Biochem. Z.*, 1923, 136, 128—139).—The action of positively charged  $\alpha$ -rays and of radium-*F* on hæmoglobin and suspensions of corpuscles in isotonic sodium chloride solution is to effect a change in the form of the curves obtained by plotting the carbon dioxide in combination against the tension. The results are held to support the authors' views on the existence of an electrical double layer at the boundary surface of corpuscles,  $\alpha$ -rays neutralising the negative charge. H. K.

**An Uneven Ionic Exchange between Corpuscles and Phosphate Buffer Mixtures of Increasing Hydrogen-ion Concentration.** CHRISTMAN KROETZ (*Biochem. Z.*, 1923, 136, 250—265).—When washed corpuscles were added to phosphate mixtures of known  $p_H$  and then centrifuged after fifteen minutes, the  $p_H$  redetermined colorimetrically was always more alkaline, and although the original phosphate mixtures made up were of increasing  $p_H$ , the redetermined values after treatment with corpuscles, although higher, showed a tendency to retain a constant

value. An analogy is drawn with the parallel results of the carbon dioxide combination curve of hæmoglobin of Straub and Meier.

H. K.

**Inorganic Phosphorus of the Serum and Plasma of Ninety-one Normal Adults as Determined by the Bell and Doisy Method.** EDWARD TOLSTOI (*J. Biol. Chem.*, 1923, 55, 157—160).—The values found lie between 2.5 and 3.3 mg. of phosphorus per 100 c.c. Practically identical values were obtained for plasma and serum, provided the latter was not left for too great a time in contact with the clot.

E. S.

**The Increase of Calcium-ions in Human Serum after Intravenous Injection of Calcium Salts.** ERNST SIEBURG and ADOLF KESSLER (*Arch. expl. Path. Pharm.*, 1923, 96, 180—192).—After the injection of aqueous solutions of various calcium salts (chloride, formate, propionate, lactate) in amounts sufficient to double the calcium content of the blood, the concentration of calcium-ions (as distinct from total calcium) in the serum returned to the normal within half an hour. The effect of calcium hypophosphite was of shorter duration, probably owing to its rapid oxidation to phosphate. Admixture of the salts with gum arabic or agar-agar increased the time by about 25%; gelatin, however, had no such effect. Separate experiments on rabbits indicate that the condition of lipæmia has no influence on the rate of disappearance of injected calcium-ions.

E. S.

**Comparative Content of Plasma and of Serum in Lipoids.** (MME) PAULETTE JUNG and RENÉ WOLFF (*Bull. Soc. Chim. biol.*, 1923, 5, 137—147).—The blood lipoids appear to pass into the serum on coagulation, as the content of the serum in them is greater than that of the plasma. This difference is less, and in fact sometimes does not exist, in blood taken from fasting animals, and in those not fasting the difference varies, to some extent depending on the food which is being digested.

W. O. K.

**Mode of Action of Formaldehyde with the Colloids of the Organism. II.** H. KÜRTEN (*Biochem. Z.*, 1923, 135, 536—545).—Further experiments in support of the view that formaldehyde alters the state of serum proteins by a reversal of the state of swelling. The viscosity of the globulin and albumin fractions of sera were determined and compared with the value after heating at 60° for two hours. These values were then compared with the viscosities obtained after treatment with dilute formaldehyde solution. In each case the heated serum showed a greater reactivity to formaldehyde than the unheated.

H. K.

**So-called Anti-enzymes.** EMIL ABDERHALDEN and ERNST WERTHEIMER (*Fermentforsch.*, 1922, 6, 286—301).—The authors have made experiments with rabbits to ascertain if intravenous injection of an enzyme solution results in the appearance in the blood-serum of a substance with anti-enzymic properties, the enzymes employed being: polypeptidase from yeast maceration

juice and from pancreas, diastase from liver, lipase from pancreas, and saccharase obtained from yeast by Euler's method. In all cases were negative results obtained (cf. Knaff-Lenz, A., 1922, i, 694). Even highly active saccharase preparations are incapable of undergoing dialysis.

T. H. P.

**Hæmolytic Experiments with Salts of the Alkalis and Alkaline-earths under Normal and Pathological Conditions.** KURT BECKMANN (*Biochem. Z.*, 1923, 135, 317—328).—Contrary to Hamburger's results, but in agreement with Höber's, the degree of hæmolysis of blood-corpuscles is not the same for isotonic solutions. Over the range of hæmolysis from 0 to 100%, the kations combined with chloridion produce hæmolysis in the following order of effectiveness:  $K > Rb > Li > Na > Cs$ ;  $Ca > Ba > Sr, Mg$ , and for the anions in combination with potassium

$I > SCN > Cl > Br > NO_3 > SO_4$ .

Under pathological conditions, the same sequence of ions holds good with slight variations.

H. K.

**Does Injection of Peptone to Prevent Clotting Interfere with the Gaseous Metabolism?** G. KELEMEN (*Biochem. Z.*, 1923, 136, 154—158).—In experiments on a dog which received an intravenous injection of a 5% solution of Witte peptone to prevent blood-clotting, the oxygen consumption was considerably reduced and in all cases the respiratory coefficient increased. The conclusion is drawn that peptone cannot be used in experiments on the gaseous metabolism.

H. K.

**Chemical Kinetics of the Digestion of Carbohydrates in the Duodenum of Mammals.** CARL BÖHNE (*Fermentforsch.*, 1922, 6, 200—229).—The principal co-enzymes of the diastase of the pancreas in the animal organism are phosphates, carbonates, and sodium chloride. In presence of potassium dihydrogen phosphate, 2% amylose solution having  $p_H$  4.6—5 is digested by the enzyme in one hundred minutes, whilst with disodium hydrogen phosphate and  $p_H$  8.4—9.1, twelve hours are required. The activity of the two phosphate-diastases increases as the hydrogen-ion concentration approaches the neutral point. When a mixture of the two phosphates is present and the value of  $p_H$  is 5.9—6.9, the digestion occupies eighty minutes. In presence of sodium hydrogen carbonate and with  $p_H$  8.3, digestion is complete in twelve hours, but the intensity of the action varies with the concentration of the salt; if the latter is partly saturated with carbon dioxide, so that  $p_H$  becomes 6.7, the time of digestion is reduced to eighty minutes.

These results, depending mainly on the concentration of the hydrogen-ions, undergo marked alteration if small proportions of sodium chloride are added to the digestion mixture. If the latter has an alkaline reaction, sodium chloride activates the digestion to such an extent that the duration may be shortened from twelve hours to sixty to seventy minutes. Similar accelerating effects are produced by sodium chloride when the digestion liquid has

an acid reaction due to the presence of a mixture of either potassium dihydrogen phosphate and disodium hydrogen phosphate or sodium hydrogen carbonate and carbon dioxide. No explanation is advanced of the observation that, with either of these mixtures as co-enzyme, the optimum reaction for pancreatic diastase is displaced by sodium chloride towards the neutral point.

Thus the anions of the diastase-salt complexes,  $\text{Cl}'$ ,  $\text{HCO}_3'$ ,  $\text{H}_2\text{PO}_4'$ , and  $\text{HPO}_4''$ , effect conversion of an inactive, resting enzyme into the active state, the course of the digestive process being governed mainly by the hydrogen-ion concentration and, to a less extent, by the concentration of the added salt.

The physiological consequences of these results are discussed.

T. H. P.

**Carbohydrate Metabolism in Avitaminosis. II. Glycogen.** J. A. COLLAZO (*Biochem. Z.*, 1923, **136**, 20—25).—Deficiency of vitamins *A*, *B*, and *C* leads to a hyperglycæmic state in doves, fowls, guinea-pigs, and dogs, in which there is also a disappearance of glycogen from the various depôts. Under parallel conditions, fasting animals with slight hyperglycæmia show a higher liver, heart, and muscle content of glycogen.

H. K.

**Carbohydrate Metabolism in Avitaminosis. III. Influence of Dextrose Administration.** J. A. COLLAZO (*Biochem. Z.*, 1923, **136**, 26—37).—The author has examined the effect on the blood-sugar of the oral, rectal, intraperitoneal, intravenous, and subcutaneous administration of dextrose in large and small quantities to normal or fasting dogs or to dogs suffering from avitaminosis. Large doses (80 g.) in avitaminosis produce a more pronounced and protracted hyperglycæmia than in fasting or normal animals, whilst small doses (5 to 10 g.) produce in all cases a slight hyperglycæmia followed by a return to the normal level in normal and fasting dogs, but showing a transient hypoglycæmia in avitaminosis.

H. K.

**Carbohydrate Metabolism in Avitaminosis. IV.** J. A. COLLAZO (*Biochem. Z.*, 1923, **136**, 278—290).—Administration of carbohydrates to animals in a state of avitaminosis produces toxic symptoms. Dextrose, lævulose, and galactose are highly toxic, sucrose, lactose, and maltose less toxic, and starch least of all. If vitamins (yeast) be given at the first manifestations of toxic symptoms, these symptoms vanish and the hyperglycæmic condition of the blood subsides. Five g. of yeast were always found sufficient to counteract 10 g. of dextrose. It is concluded that vitamins are essential to the cells for the metabolism of carbohydrates.

H. K.

**The Action of Thyroxin and of Very Small Amounts of Iodine [Potassium Iodide] on the Metabolism.** FRITZ HILDEBRANDT (*Arch. exp. Path. Pharm.*, 1923, **96**, 292—304).—The identity of the physiological effects (increased oxygen consumption and decrease in body-weight) produced by injections of thyroxin and by the administration of thyroid gland by the mouth, observed

by Kendall, has been confirmed for rats. The effect of a thyroid-gland diet on rats is decreased by injection of small amounts of potassium iodide and increased by larger amounts. That the result in the former case is not due to an inhibition of the function of the thyroid gland has been shown by experiments on thyroid-ectomised animals.

E. S.

**Proteolytic Enzymes of the Lymph Glands.** S. G. HEDIN (*Z. physiol. Chem.*, 1923, **125**, 289—296).—When lymph glands are treated with dilute acid and subsequently extracted with a solution of casein, two enzymes are obtained, one with an optimum reaction of  $p_H$  5.5, and an erepsin, with the optimum reaction  $p_H$  8. If the glands are further extracted with a solution of sodium chloride, another proteolytic enzyme is obtained, optimum  $p_H$  9—10.

W. O. K.

**Oil of the Liver of *Squalus acanthias* from Moroccan Waters.** SERGIO BERLINGOZZI and MARIA TOMASINI (*Ann. Chim. Appl.*, 1923, **7**, 29—33).—This oil, expressed from the liver of the young fish, closely resembles cod-liver oil in its physical and chemical constants, and is readily converted into a solid fat by hydrogenation [cf. *J.S.C.I.*, 1923, May].

T. H. P.

**Pancreatic Enzymes. III. Pancreas Amylase.** RICHARD WILLSTÄTTER, ERNST WALDSCHMIDT-LEITZ, and ALBERT R. F. HESSE (*Z. physiol. Chem.*, 1923, **126**, 143—168; cf. this vol., i, 403).—The action of amylase in the glycerol extract of dried pancreas is influenced by the presence of salts and by the hydrogen-ion concentration. The production of sugar from starch follows approximately a unimolecular reaction, and is proportional to the amount of enzyme present. On the basis of these findings, a method is devised for the estimation of amylase, the result being expressed in amylase units, an amylase unit being that amount for which, under given conditions, the constant of unimolecular reaction is 0.01. The amylase value of a preparation is the number of amylase units in 1 cg.

To isolate amylase from the crude extract of pancreas, the lipase is adsorbed on aluminium hydroxide, and then the trypsin is adsorbed by kaolin from a solution made slightly acid with acetic acid. The amylase is further purified by adsorption from 50% alcohol. The adsorbability of amylase decreases with increasing purity. An amylase preparation with an amylase value of at least 1205 has been obtained. The purified material showed no protein reactions, but still gave Molisch's reaction. W. O. K.

**Polypeptide-cleaving Enzyme System in Pancreas Press-juice. Action of Vegetable Mucus on Enzyme Extracts of the Pancreas.** A. FODOR (*Fermentforsch.*, 1922, **6**, 269—285; cf. A., 1920, i, 464; 1921, i, 701).—By the method used to separate phosphorus-containing proteins in the sol-forming condition from yeast extracts, it is possible to obtain from pressed or maceration juice of the pancreas a phosphorus-containing protein approaching closely in composition those of yeast, but showing greater variations

in nitrogen and phosphorus content; thus purer products are obtainable from yeast juices than from animal cells and tissues.

The condition of the colloids in the pancreatic maceration juice has been investigated ultramicroscopically and experiments have been made on the influence exerted by carrageen extract on the polypeptidolytic activity of the juice. The results obtained indicate that the protein is the principal carrier of the enzyme action, but that the lipoids of the pancreas cells favour the suspensibility and the distribution of the enzyme colloids over large surfaces in virtue of their power of retarding aggregation and molecular agglomeration. The possibility of a connexion between enzymic activity and phosphorus content is discussed.

T. H. P.

**Tethelin: a Growth-controlling Substance obtainable from the Anterior Lobe of the Pituitary Body.** THORBURN BRAILSFORD ROBERTSON (*Biochem. J.*, 1923, **17**, 77—82).—Polemical. The author asserts that Drummond and Cannan's repetition of his work (A., 1922, i, 491) was vitiated by a faulty method of preparation of tethelin and by not adopting the statistical method of comparing the growth of animals receiving this dietary principle with that of normal animals.

S. S. Z.

**Muscle Respiration and Sarcoplasma.** GUSTAV EMBDEN and HERMANN LANGE (*Z. physiol. Chem.*, 1923, **125**, 258—283).—The skeletal muscles of frogs, if immersed in isotonic sucrose solution after being in Ringer's solution, show marked increase in oxygen consumption and increased liberation of phosphoric acid. These increases are accompanied by marked swelling of the sarcoplasma, and are greatest at a certain optimum swelling.

W. O. K.

**The Selective Absorption of Potassium by Animal Cells. III. The Effect of Hydrogen-ion Concentration on the Retention of Potassium.** RALPH E. STANTON (*J. Gen. Physiol.*, 1923, **5**, 461—468).—By perfusing frog's muscles with potassium-free Ringer solution of  $P_H$  from 6.0 to 8.0, it is shown that within this range the hydrogen-ion concentration has little or no effect on the retention of potassium.

W. O. K.

**Cholesterol Content of Various Muscles of Rabbits.** GUSTAV EMBDEN and HEINZ LAWACZECK (*Z. physiol. Chem.*, 1923, **125**, 199—209).—The cholesterol content of various muscles in rabbits has been determined by heating the muscle with a 25% solution of potassium hydroxide, extracting with ether, evaporating the ethereal extract, and using an aliquot part of the chloroform extract for colorimetric estimation (heating with acetic anhydride and sulphuric acid). The white musculus biceps femoris contains about 0.04—0.06% of cholesterol, the red musculus semitendinosus, and the diaphragm 0.07—0.10%, whilst the heart contains 0.12—0.16%.

W. O. K.

**The Cholesterol Content of Various Muscles.** HEINZ LAWACZECK (*Z. physiol. Chem.*, 1923, **125**, 210—219).—The cholesterol content of the muscles of various animals has been

investigated. It is concluded that in general there is a very strong parallelism between cholesterol content and resistance to fatigue.

W. O. K.

**Chemical Differences between Skeletal Muscles of the Calf and the Ox.** KAZUO HOTTA (*Z. physiol. Chem.*, 1923, 125, 220—228).—Analyses have been made of the nitrogen, cholesterol, and phosphoric acid contents of the biceps of the calf and the ox. There is more cholesterol, and correspondingly more "rest"-phosphoric acid, in the muscle of the calf than of the ox.

W. O. K.

**The Interconversion of Creatine and Creatinine. IV. Origin of Creatinine in the Organism.** AMANDUS HAHN and GEORG MEYER (*Z. Biol.*, 1923, 78, 91—118; cf. this vol., ii, 195).—Quantitative experiments on the serum, blood, liver, and kidney of the ox and on the liver of the pig and dog show that during sterile autolysis at 38° there is no destruction either of creatine or of creatinine and no interconversion of these substances. Where occasionally an increased creatinine content was observed, it was shown to be due to the development of acidity, for, by the use of buffer mixtures of the same acidity and added creatine, a transformation into creatinine followed. Ferments for the interconversion of creatine and creatinine or their destruction are non-existent. Similar relations hold for creatinine and creatine in urine. When creatine is taken by mouth in solution by man, there is no increased creatinine output in the urine. Subcutaneous injections of creatine in the rabbit do not cause an increased creatinine excretion, and the whole of the creatine is excreted in twenty-four hours. The origin of creatinine in man is ascribed to transformation of the creatine of muscle brought about by the reaction of the tissue.

H. K.

**Pigment in Horse Hair.** KARL TUTSCHKU (*Biochem. Z.*, 1923, 135, 585—586).—The hair of various coloured horses after washing with water was covered with a mixture of 75% alcohol and ether (9 : 1) for ten weeks. The solvent acquired a yellowish-green colour and gave the colour reactions for lipochrome with sulphuric acid and with nitric acid. The crystals obtained on removal of the solvent gave the Liebermann cholesterol reaction. If the hair is first of all treated with potassium hydroxide and filtered, the filtrate is free from lipochrome, but the insoluble matter when extracted with the alcohol-ether mixture gives the lipochrome reaction.

H. K.

**Structural Colour in Feathers. I.** CLYDE W. MASON (*J. Physical Chem.*, 1923, 27, 201—251).—The colours of feathers have been investigated. It is shown that the non-iridescent blue of feathers is due to the scattering of blue light by very fine pores in the walls of the outer layer of cells of the barbs of the feathers. This is the blue described by Tyndall, which is commonly observed in turbid media. No blue pigments, and no other structural causes of blue colour, have been observed in non-iridescent feathers.

Green feathers are essentially the same as blue feathers, except that the blue cells are overlaid by a transparent, yellow layer.

J. F. S.

**Substances Extracted from *Eledone moschata*.** I. D. ACKERMANN, F. HOLTZ, and F. KUTSCHER (*Z. Biol.*, 1923, 77, 241—244).—Adenine and arginine have been isolated from the mussel, *Eledone moschata*.

W. O. K.

**Chemical Composition of Coral from the Tyrrhenum.** N. PASSERINI (*Gazzetta*, 1923, 53, i, 35—40).—The percentage composition of bright red coral (*d* 2.640) gathered in the Tyrrhenian Sea about 10 kilometres south of Leghorn and air-dried, is found to be: water, 0.600; organic matter, 2.545; calcium carbonate, 85.495; magnesium carbonate, 9.102; calcium sulphate, 1.230; other mineral constituents and loss, 1.028; manganese and iron, scarcely detectable traces. These results are compared with those of other investigators.

T. H. P.

**The Sterol Content of Cow's Milk.** FRANCIS WILLIAM FOX and JOHN ADDYMAN GARDNER (*Biochem. J.*, 1921, 17, 94—102).—Cholesterol is present in milk in the free state and in the form of esters. These compounds are found to be present in proportions of 0.351 g. to 100 g. of milk-fat—a figure which is in close agreement with those obtained by other workers. The output of cholesterol appears to follow approximately the output of fat. Although most of the cholesterol (free and ester) is present dissolved in the milk fat, some of it is also present in another form in the milk. The fraction which is precipitated from the unsaponifiable fraction of milk by digitonin consists entirely of cholesterol. The remaining portion of the unsaponifiable fraction consists of oils which are in part at least stable esters capable of withstanding saponification by alkali. The chemical behaviour of these oils is described.

S. S. Z.

**The Rate of Decline of Milk Secretion with the Advance of the Period of Lactation.** SAMUEL BRODY, ARTHUR C. RAGSDALE, and CHARLES W. TURNER (*J. Gen. Physiol.*, 1923, 5, 441—444).—The average daily production of milk varies with the month of lactation, and is found to be given by the formula  $M_t = M_0 e^{-kt}$ , where  $M_0$  and  $k$  vary with the breed of cows. This is the formula of a unimolecular chemical reaction, and the result is considered to confirm the view that milk secretion is limited by a chemical reaction.

W. O. K.

**Influence of the Acid and Base Content of the Food on the Composition of the Urine of Growing Dogs.** JONAS BORAK (*Biochem. Z.*, 1923, 135, 480—492).—From consecutive experiments on a single dog or parallel experiments on two dogs of a litter, it was found that feeding with foodstuffs of an acid character such as rye meal, rye bread, or tripe resulted in a greater increase of weight than feeding with foodstuffs of a basic character such as milk, potatoes, carrots, and soja beans. The difference is

attributed to retention of water by the dogs fed on an acid diet, as nitrogen estimations on the food and urine showed a greater nitrogen excretion on an acidic diet than on a basic one, although the volume of urine in the former case was less than in the latter.

H. K.

**Influence of the Composition of Food on the Calcium Output.** B. SJOLLEMA (*Proc. K. Akad. Wetensch. Amsterdam*, 1923, 25, 395—398).—The variation of the amount of calcium and phosphorus in the faeces of a rabbit fed on various foods to which various amounts (3—12%) of non-digestible ballast have been added (such as oat straw or sawdust which had been boiled with acid and alkali) has been determined. The experiments show that an increase of the amount of non-digestible matter in the food causes a greater loss of calcium via the intestinal canal. All the calcium present in the faeces is not necessarily derived directly from the food, a large portion of it may be supplied by the organism, from which it is concluded that calcium plays a rôle in the production of faeces. In view of this, it follows that only under certain conditions can an examination of the faeces show whether calcium occurs in an available form in the food or in any part of it. In animals which are yielding much milk, feeding with much ballast increases the danger of a negative calcium balance.

J. F. S.

**The Selective Action of the Kidney as Regards the Excretion of Inorganic Salts.** W. DENIS (*J. Biol. Chem.*, 1923, 55, 171—181).—Analyses of the blood of dogs following the administration by the intestine or intravenously of magnesium sulphate, sodium sulphate, magnesium chloride, sodium chloride, and sodium phosphate indicate that the kidney exercises a selective retention for the sulphate-ion.

E. S.

**Rate of Excretion of Urea. V. The Effect of Changes in Concentration of Urea in the Blood on the Rate of Excretion of Urea.** T. ADDIS and D. R. DRURY (*J. Biol. Chem.*, 1923, 55, 105—111; cf. A., 1916, i, 352, 864; 1917, i, 367).—Under special conditions, the chief of which is abstention from food, the rate of excretion of urea is directly proportional to its concentration in the blood (cf. also Austin, Stillman, and Van Slyke, A., 1921, i, 383).

E. S.

**Rate of Excretion of Urea. VI. The Effect of Very High Blood Urea Concentrations on the Rate of Excretion of Urea.** D. R. DRURY (*J. Biol. Chem.*, 1923, 55, 113—118).—Experiments on rabbits indicate that the relation between the rate of excretion of urea and its concentration in the blood (preceding abstract) holds even when the latter is increased by injection to more than 700 mg. per 100 c.c.

E. S.

**Constituents of the Urine Known as "Oxyproteic Acid."** E. FREUND and ANNA SITTENBERGER-KRAFT (*Biochem. Z.*, 1923, 136, 145—153).—The preparation of oxyproteic acid from the

urine of carcinomatous patients is described and depends on the removal of foreign substances by alkaline copper sulphate and precipitation of the required acid by mercuric acetate. The amorphous barium salt precipitated by alcohol corresponds with an acid,  $C_{10}H_{22}O_{10}N_2$ . It had no characteristic protein reactions, but is possibly a derivative of carbamide, which it yields on hydrolysis.

H. K.

### Hydrogen-ion Concentration of the Blood in Carcinoma. I. From the Colorimetric Estimation of the Blood Dialysate.

WILLIAM H. CHAMBERS (*J. Biol. Chem.*, 1923, **55**, 229—255).—Estimations were made of the hydrogen-ion concentration of the dialysates from the venous blood of normal subjects and of patients suffering from carcinoma and other diseases. The method employed was similar to that of Dale and Evans (*A.*, 1921, i, 142); loss of carbon dioxide was prevented by carrying out the various stages under a layer of oil. The following are the average  $P_H$  values found at 20°: normal subjects 7.31, carcinoma cases 7.45, pathological cases other than carcinoma 7.36. The dialysates from the carcinoma patients were thus distinctly more alkaline than the others; the individual values show, further, that, in general, the alkalinity increased with the size of the tumour.

E. S.

### Hydrogen-ion Concentration of the Blood in Carcinoma. II. From the Carbon Dioxide-Bicarbonate Ratio.

WILLIAM H. CHAMBERS and R. E. KLEINSCHMIDT (*J. Biol. Chem.*, 1923, **55**, 257—290).—When calculated from the carbon dioxide-bicarbonate ratio, the hydrogen-ion concentration of the venous blood of carcinoma patients was found not to differ from that of normal subjects. The following are the average  $P_H$  values found at 38°: normal subjects 7.29, carcinoma cases 7.34, pathological cases other than carcinoma 7.33. The value found for normal blood at 38° thus agrees with that obtained from the dialysate at 20° (preceding abstract); at 38°, however, the latter would have a greater  $P_H$  value than the former. This greater alkalinity of the dialysate is explained by the authors on the basis of Donnan's theory of membrane equilibria. The same theory indicates that the still greater alkalinity of the dialysates from the blood of carcinoma patients is due to an increase of non-diffusible anions in the plasma.

E. S.

**Zinc in Cancerous Tissues. Physicopathology of Zinc, and, Particularly, its Significance in Tumours.** PAUL CRISTOL (*Bull. Soc. Chim. biol.*, 1923, **5**, 23—40).—Estimations have been made of the zinc present in the liver, spleen, and blood in a case of leucæmia, and in a large number of tumour tissues. The zinc content appears to vary with the activity of the tumour.

W. O. K.

**Behaviour of Cholesterol in Pigeon-Beri-beri.** HEINZ LAWACZECK (*Z. physiol. Chem.*, 1923, **125**, 229—247).—There is an increase of cholesterol in the skeletal muscles of pigeons suffering from avian beri-beri.

W. O. K.

**Influence of Cholesterol on the Consumption of Oxygen by Lecithin.** HERMANN LANGE and HEINZ LAWACZECK (*Z. physiol. Chem.*, 1923, 125, 248—257).—Ciaccio has shown that there is a diminution of lecithin, whilst Lawaczek (preceding abstract) shows there is an increase of cholesterol, in skeletal muscles in avian beri-beri. The antagonistic action of cholesterol and lecithin on intercellular respiration deduced from this is confirmed in the present research. The addition of cholesterol to an emulsion of lecithin containing ferric chloride influences the consumption of oxygen by the lecithin, a maximum being attained when a certain proportion of cholesterol to lecithin is present.

W. O. K.

**Change in the Nature of the Blood-sugar of Diabetics caused by Insulin.** W. DEVEREUX FORREST, W. SMITH, and L. B. WINTER (*J. Physiol.*, 1923, 57, 224—233).—The two last-named authors have recently shown (*J. Physiol.*, 1922, 57, 100) that the normal blood-sugar in man and in animals has a lower rotatory power than would be given by the  $\alpha$ - $\beta$ -equilibrium form of glucose as deduced from the copper reduction value. The sugar gives an osazone with the same crystalline form and melting point as that of glucosazone. The instability of the sugar is shown by its transient rotatory power, the curve of the polarimeter readings reaching the copper reduction value in three or four days in acid solution. The sugar at first decolorises potassium permanganate more rapidly than a solution of  $\alpha$ - $\beta$ -glucose in similar concentration. This distinction no longer obtains when the polarimeter reading corresponds with that of  $\alpha$ - $\beta$ -glucose. These facts, in conjunction with the work of Hewitt and Pryde (*A.*, 1920, i, 508, 648) on sugar solutions introduced into the intestine, suggest that normal blood-sugar is  $\gamma$ -glucose. In diabetes, it is shown that this sugar is not present in amounts capable of detection by the method employed. The polarimeter reading in this disease is initially greater than the copper reduction value, suggesting that, besides  $\alpha$ - $\beta$ -glucose, disaccharides or other substances with a higher polarimeter : copper reduction ratio are present in the blood of diabetic persons. It is suggested that  $\alpha$ - $\beta$ -glucose cannot be directly stored or utilised, but that an enzyme is responsible for the conversion of  $\alpha$ - $\beta$ -glucose into  $\gamma$ -glucose; the absence of this enzyme is suggested as the direct cause of diabetes mellitus.

In the present communication, the above observations are confirmed in seven cases. The greatest change in the rotation observed, due to the administration of insulin, was  $0.15^\circ$ , the smallest about  $0.01^\circ$  (cf. also *Annual Reports*, 1923, 49, 195).

G. B.

**An Enzyme Responsible for Alteration of the Rotatory Powers of Glucose and Fructose. Some Evidence for the Existence of Polysaccharides in the Blood of Diabetics. The Lowering of the Blood-sugar by an Extract of Yeast.** L. B. WINTER and W. SMITH (*Proc. Physiol. Soc.*, 1922, 1923; *J. Physiol.*, 1923, 57, xiii, xxxi, xl).—I. The enzyme appears to be present in the liver. Glucose and fructose solutions incubated

with very small amounts of insulin and liver extract have their rotations altered in a downward and upward direction, respectively. The insulin preparations are thermostable in this respect, and always contained phosphates; addition of phosphates accelerates the change in rotation. Boiled liver extracts are inactive.

II. Further evidence is obtained of the occurrence of polysaccharides (cf. preceding abstract).

III. A solid preparation of yeast has been obtained, which, like insulin, definitely lowers the blood-sugar on injection into rabbits. Rats, when it is injected, die in convulsions similar to those caused by insulin.

G. B.

**Influence of the Nutritional Condition of the Animal on the Hypoglycæmia Produced by Insulin.** N. A. McCORMICK, J. J. R. MACLEOD, E. C. NOBLE, and K. O'BRIEN (*J. Physiol.*, 1923, 57, 234—252; cf. *Annual Reports*, 1923, 19, 196).—The amount of glycogen in the animal has a distinct influence on the dose of insulin required to produce a given lowering of the blood-sugar, or to produce convulsions. Hence it is impossible to make a precise physiological assay of insulin by determining the percentage of blood-sugar at varying periods after the injection. An approximate assay can best be made by determining the blood-sugar ninety minutes, and three hours, after the injection in animals which have had no food for twenty-four hours.

G. B.

**Ammonia Content of the Blood in Nephritis.** DOROTHY STUART RUSSELL (*Biochem. J.*, 1923, 17, 72—76).—Estimations of blood-ammonia in a series of cases of advanced renal disease showed values under 0.1 mg.%. These values are of the same order as those found in the blood of normal patients. The author suggests that this observation lends support to Nash and Benedict's hypothesis that the ammonia formation in the body takes place in the kidneys.

S. S. Z.

**The Inorganic Constituents of the Blood-serum in Nephritis.** W. DENIS and S. HOBSON (*J. Biol. Chem.*, 1923, 55, 183—190).—The sera of twenty-two patients suffering from nephritis and cardiorenal disease have been analysed for non-protein nitrogen, creatinine, uric acid, and inorganic constituents. No marked regularity in the results has been observed. In many cases, a high value was obtained for the sulphate-ion, which appears to be excreted with more difficulty than any other inorganic radicle normally present in the blood.

E. S.

**Analysis of Bone Ash in Cases of War Osteopathy.** WILHELM LOLL (*Biochem. Z.*, 1923, 135, 493—503).—An analysis has been made of the bones of four severe cases of war osteopathy. Normal human bones contain CaO, 51.8—52.1%, MgO, 0.78—0.85%, and P<sub>2</sub>O<sub>5</sub>, 38.8%. In war osteopathy, the ribs and pelvis contain CaO, 56.8—76.8%, MgO, 0.74—0.8%, and P<sub>2</sub>O<sub>5</sub>, 16.2—37.3%. The composition of the tibia was nearly normal.

H. K.

**Experimental Tetany. I. Distribution of Calcium in the Plasma and Cells. II. Variation in Colloidal and Ionic Calcium.** E. W. H. CRICKSHANK (*Biochem. J.*, 1923, 17, 13—29).—An immediate state of alkalosis which is not necessarily marked follows parathyroidectomy and with the onset of severe tetany it passes rapidly into a condition of acidosis. There is an immediate relief of the condition in dogs on withdrawing 70—100 c.c. of blood, which suggests a toxic causative factor. In tetany there was observed a loss of calcium amounting to 37.2% for whole blood, 54.4% for the cells, and 35.2% for the plasma. The diffusible calcium in sera of parathyroid tetanic animals amounted to 94% of the total calcium, whilst in the serum of normal animals the diffusible calcium was only 60—70% of the total calcium. The author concludes that the calcium deficiency and the great loss of colloidal calcium are due to a rapid protein disintegration.

S. S. Z.

**The Physiological Action of Amino-acid Esters.** MINORU ARAI (*Biochem. Z.*, 1923, 136, 203—212).—The physiological actions of histidine methyl ester, tyrosine ethyl ester, *dl*-phenyl-alanine ethyl ester, *l*-leucine ethyl ester, *l*-cystine ethyl ester, and glycine ethyl ester have been examined. In general, the action is weak. On the blood-pressure, they may have a pressor or depressor effect, depending on the animal used, and on the isolated uterus they have a stimulating action. The actions are similar to those of the corresponding amines.

H. K.

**Hydrolysis of Amides in the Animal Body. The Comparative Stability of Surface Active Homologues in Relation to the Mechanism of Enzyme Action.** CYRUS H. FISKE (*J. Biol. Chem.*, 1923, 55, 191—220).—Acetamide, propionamide, *n*-butyramide, and *n*-valeramide were injected subcutaneously into cats and the amount of unchanged amide excreted in the urine estimated in each case. The results indicate that the rate of hydrolysis of amides in the animal organism increases with the length of the carbon chain, the order of stability *in vivo* thus being the reverse of that shown *in vitro*. Attention is directed to other reactions (hydrolysis of esters, oxidative processes) in which a similar relation holds. Since the tendency to adsorption of homologous compounds increases with the length of the carbon chain, it is suggested that the greater reactivity in the body of the higher homologues is due to the greater ease with which they are adsorbed by enzymes.

E. S.

**The Relation between the Chemical Constitution of Proteinogenous Amines and their Effect on Body Temperature and Blood Pressure.** M. CLOETTA and F. WÜNSCHE (*Arch. exp. Path. Pharm.*, 1923, 96, 307—329).—The following new substances have been obtained: ethyl carbethoxyglutamate; carbethoxyglutamodiamide, m. p. 179° (corr.); pyroglutaminamide, glistening scales, m. p. 103° (corr.); diacetyltyrosine ethyl ester, fine white needles, m. p. 86° (corr.); dicarbethoxytyrosine, m. p. 97° (corr.); diacetyltyramine, m. p. 103° (corr.); carbethoxytyramine, m. p. 80—81° (corr.); nitrotyramine, a yellow powder, m. p. 210°

(corr.); *aminotyramine*, long, white crystals, m. p. 225° (decomp.); *p-hydroxyphenylethylcarbamide*, glistening, white scales, m. p. 132° (corr.). The effect of these and other substances on body temperature and blood pressure has been investigated. W. O. K.

**Influence of Aliphatic Narcotics on the Swelling of Cell Colloids.** M. KOCHMANN (*Biochem. Z.*, 1923, 136, 49—65).—The action of the first five normal chain aliphatic alcohols, of chloral hydrate, urethane, chloroform, and ether on the swelling of finely powdered fibrin and on the gastrocnemius muscle of the frog has been examined in relation to narcosis. The order in which the narcotics inhibit the swelling of fibrin particles is approximately the same as the order of their narcotic activity towards the electrically stimulated gastrocnemius muscle. The results support the theory of narcosis that narcotics change the permeability of the cells by removal of water. H. K.

## Chemistry of Vegetable Physiology and Agriculture.

**The Botulinus Toxin.** KONRAD SCHÜBEL (*Arch. exp. Path. Pharm.*, 1923, 96, 193—259).—When cultivated in a bouillon medium, *Bacillus botulinus* gives rise to gaseous products, amongst which carbon dioxide, hydrogen sulphide, and hydrogen have been identified. At the same time, the medium becomes distinctly acid owing to the production of *n*-butyric acid and small quantities of other organic acids. In addition to these products, butyl alcohol, isobutyl alcohol, ammonia, and trimethylamine have been isolated; qualitative tests indicating the presence of small quantities of an aldehyde have also been obtained. From the quantitative results, the author concludes that the dextrose contained in the medium is decomposed mainly into butyl alcohol and butyric acid, according to the equation  $2C_6H_{12}O_6 = C_4H_8O_2 + C_4H_{10}O + 4CO_2 + 2H_2 + H_2O$ .

The botulinus toxin may be partly separated from colloidal material by ultra-filtration. It is insoluble in alcohol, acetone, chloroform, or ether, is readily destroyed by boiling its solution for a few moments, but is stable to air and light. Alkalis destroy it more readily than hydrochloric acid; concentrations of 0.91% of the latter are necessary for destructive effects to become apparent. The toxin is precipitated from solution by salts of the heavy metals, by certain protein and alkaloid precipitants, and by saturation with ammonium sulphate. It is adsorbed by animal charcoal and by certain inorganic colloids; its behaviour in this respect suggests that it possesses a negative charge. It dialyses readily through parchment and collodion membranes, its toxic properties being thereby apparently increased. Pepsin and trypsin are without action on it.

The pharmacological action of the toxin has also been investigated. E. S.

**The Formation of Dextrorotatory  $\beta$ -Furyl-lactic Acid by *Bacillus proteus*.** TAKAOKI SASAKI and ICHIRO OTSUKO (*Biochem. Z.*, 1923, **135**, 504—505; cf. A., 1922, i, 302).—d- $\beta$ -Furyl-lactic acid is formed in small yield by the action of *Bacillus proteus* on dl- $\beta$ -furylalanine. It has m. p. 95—96° and  $[\alpha]_D^{25} + 27.36^\circ$  in water.

H. K.

**Formation of Mercaptan from l-Cystine by *Bacteria*.** MASATOSHI KONDO (*Biochem. Z.*, 1923, **136**, 198—202).—*Proteus vulgaris* produces mercaptan from l-cystine in presence of lactose, dextrose, sucrose, glycerol, and histidine, but *Bacillus coli* is variable in its action. Both, however, produce hydrogen sulphide from l-cystine, and also probably ethyl sulphide.

H. K.

**Culture of *Bacillus pyocyaneus* on Definite Chemical Media.** A. LIOT (*Ann. Inst. Pasteur*, 1923, **37**, 234—274).—*Bacillus pyocyaneus*, which produces normally a blue pigment in the medium on which it is grown, will grow on agar if a suitable source of nitrogen is added. Various substances, such as ammonium salts of monobasic and dibasic fatty acids, amides, amino-acids, and alcohols and sugars, along with inorganic ammonium salts, have been investigated as to their efficiency in producing growth and pigment.

W. O. K.

**The Bactericidal Action of Tellurium Derivatives of certain Aliphatic  $\beta$ -Diketones.** GILBERT THOMAS MORGAN, EVELYN ASHLEY COOPER, and ARNOLD WIGHAM BURTT (*Biochem. J.*, 1923, **17**, 30—33).—A series of tellurium derivatives of aliphatic  $\beta$ -diketones has been tried with the purpose of ascertaining the influence of chemical constitution on the germicidal power of these compounds, and also their specific action on different micro-organisms. It is found that the bactericidal action increases considerably as the homologous series is ascended, until with a third substitution of the methyl group a limit is reached beyond which there may even be a diminution in the germicidal action.

The bactericidal action of the compounds is determined by the chemical structure of the  $\beta$ -diketone, position isomerism being a determining factor. Experiments with various organisms have disclosed that the above compounds exert a selective action on the coliform organisms. Cocci are more resistant to them. S. S. Z.

**Stimulation of Alcoholic Fermentation by Chemically Defined Substances.** T. SODA (*Biochem. Z.*, 1923, **135**, 610—620).—Cell-free fermentation of dextrose is accelerated by trimethylamine oxide, allyl alcohol, cinnamyl alcohol,  $\alpha$ -crotonic acid,  $\alpha\alpha'$ -diketopimelic acid, benzoylacetone, and  $\alpha$ -methylhexanone.

H. K.

**Enzymes. II.** A. VON EULER and KARL MYRBÄCK (*Arkiv Kem. Min. Geol.*, 1922, **8**, No. 22, 1—31).—A study, in the first place, of the autofermentation (as distinct from autolysis) of fresh bottom-yeast. Autofermentation is accelerated by toluene, but retarded if ethyl acetate is also added, more particularly in

presence of dextrose. Chloroform also inhibits the process. With dried yeast, autofermentation is inhibited by mixtures of toluene and ethyl acetate, either in presence or in absence of dextrose. The latter substance, in presence of phosphate ( $p_H$  5), retards the process, as also does sodium chloride. The inhibiting effect of toluene is more marked in presence of yeast-gum, which is itself unaffected.\*

The fermentation of dextrose by dried yeast, in presence of phosphate, is practically unaffected by the addition of lactose, which is not appreciably fermented. Lactose or toluene, or mixtures of these two substances, inhibit the autofermentation of dried yeast. Complete hydrolysis of dried yeast, before and after autofermentation, shows a loss of dextrose constituents corresponding with the carbon dioxide produced.

The second section of the paper deals with the purification and adsorption of saccharase along the lines laid down by Willstätter and Racke (A., 1921, i, 823). The results of the latter authors are confirmed in connexion with autolysis, acetone and alcohol precipitation, adsorption by aluminium hydroxide and kaolin, etc. Kieselguhr does not adsorb saccharase.

In the third section of the paper, it is shown that the inactivating effect on saccharase solutions of *p*-phenylenediamine and formaldehyde depends on the hydrogen-ion concentration (cf. Rona and Bloch, A., 1922, i, 65).  
E. E. T.

**Alcoholic Fermentation by Means of Yeast-cells under Various Conditions. V. Formation of Glycerol when the Intermediate Acetaldehyde is Retained by Animal Charcoal.** EMIL ABDERHALDEN and SUSI GLAUBACH (*Fermentforsch.*, 1922, 6, 143—148).—Neuberg's observation that acetaldehyde forms an intermediate stage in the degradation of dextrose to alcohol and carbon dioxide by means of the enzymic complex, zymase, is now supplemented by the discovery that the fixation of acetaldehyde from a fermenting or fermented solution by means of animal charcoal (A., 1922, i, 92) is accompanied by increase in the amount of glycerol formed. The extent of such increase is augmented when the quantity of charcoal present is increased.  
T. H. P.

**Alcoholic Fermentation by Means of Yeast-cells under Various Conditions. VI.** EMIL ABDERHALDEN (*Fermentforsch.*, 1922, 6, 149—161).—The influence of various substances on alcoholic fermentation (cf. Neuberg and Sandberg, A., 1922, i, 408) is as follows. Yeast maceration juice dialysate: first dialysate accelerating, second dialysate, retarding; tyrosine, at first retarding, later accelerating; di-iodotyrosine, at first accelerating, later retarding; dihydroxyphenylalanine, accelerating in small, retarding in large, doses; cystine in large doses, greatly accelerating at first and retarding later, but in smaller doses, accelerating; cysteine at first retarding but afterwards considerably accelerating; tryptophan, histidine, and, especially, arginine, accelerating; caffeine, at first accelerating, later retarding, the reverse being the case with allantoin; xanthine, or *dl*-adrenaline, greatly accelerating; diethyl-

amine, retarding; cholesterol, or homovanillin, at first retarding, later accelerating; vanillin, choline, acetylcholine, retarding.

T. H. P.

**Alcoholic Fermentation by Means of Yeast-cells under Various Conditions. VII. Influence of Animal Charcoal and other Substances on the Time-course of Alcoholic Fermentation.** EMIL ABDERHALDEN (*Fermentforsch.*, 1922, 6, 162—171).—Animal charcoal accelerates alcoholic fermentation of sugar solution to a more marked extent than either dipotassium hydrogen phosphate or sodium laevulosediphosphate, the acceleration being still further increased by use of the charcoal and one of these phosphates together. The very great retardation of the fermentation produced by toluene almost entirely disappears if animal charcoal also is present; adsorption of the toluene by the charcoal appears to be the cause of this protective action of the charcoal. The effect of toluene on fermentation by dried yeast is far less marked than when fresh yeast is used.

The initial stimulation of fermentation by dried yeast sometimes caused by toluene is confirmed, but not explained. Especially in presence of animal charcoal, toluene produces a very marked acceleration of the rate at which carbon dioxide is liberated from pyruvic acid by dried yeast.

T. H. P.

**Alcoholic Fermentation by Means of Yeast-cells under Various Conditions. VIII. Formation of Glycerol when the Intermediate Acetaldehyde is Retained by Animal Charcoal.** EMIL ABDERHALDEN and WALTER STIX (*Fermentforsch.*, 1922, 6, 345—347).—The proportion of glycerol formed during the fermentation of dextrose by yeast may be considerably increased by increase of the amount of animal charcoal present and by expelling the air from the fermentation vessel by means of carbon dioxide (cf. Abderhalden and Glaubach, preceding page).

T. H. P.

**Adsorption of Acetaldehyde and Pyruvic Acid, Separately and Together, by Animal Charcoal and Other Adsorbents.** EMIL ABDERHALDEN and HIDEKI SUZUKI (*Fermentforsch.*, 1922, 6, 137—142).—The amount of acetaldehyde or pyruvic acid adsorbed from aqueous solutions by a certain weight of animal charcoal under definite conditions increases with, but less rapidly than, the concentration of the solution. That the action represents a true reversible adsorption is shown by the results of equilibrium experiments. It appears, but it is not yet certain, that part of the adsorbed acetaldehyde undergoes change at the surface of the charcoal. When both acetaldehyde and pyruvic acid are present in solution, the amount of each adsorbed by the charcoal is diminished (cf. Abderhalden, A., 1922, i, 92; Grab, A., 1922, i, 306; Abderhalden and Glaubach, preceding page).

T. H. P.

**Formation of Citric Acid in Cultures of *Aspergillus niger* and *Penicillium glaucum* on Sugar.** WL. BUTKEWITSCH (*Biochem. Z.*, 1923, 136, 224—237).—When *Aspergillus niger* and

*Citromyces glaber* were grown on media containing sucrose in presence of calcium carbonate, citric and oxalic acids accumulate much more rapidly in the case of the former than the latter. This also happens if there be available a plentiful source of nitrogen. Evidence is adduced to show that a soluble calcium salt is formed in these solutions, but the acid has not yet been isolated. *Penicillium glaucum* is also able to produce small quantities of citric and oxalic acids in culture media of sucrose and calcium carbonate. H. K.

**The Carbamide Content of Fungi.** NICOLAUS N. IVANOV (*Biochem. Z.*, 1923, 136, 1—8).—The carbamide content of fungi varies not only from genus to genus, but also among the species of a genus, *Lycopodon echinatum*, containing 1.26% and *L. gemmatum*, 10.7%, of carbamide on the dried material. The genera *Psalliota* and *Pholiota* also show similar variations. The carbamide content increases to a maximum at the beginning of ripening, but then falls off to nothing when fully ripe. H. K.

**Formation of Carbamide in Fungi.** NICOLAUS N. IVANOV (*Biochem. Z.*, 1923, 136, 9—19).—During ripening, fungi treated with ammonia compounds can convert ammonia into carbamide. This takes place even if the mycelium be detached. The carbamide functions, it is thought, as a nitrogenous reserve substance. H. K.

**Comparative Studies on Respiration. XXIV. The Effects of Chloroform on the Respiration of Dead and of Living Tissue.** GEORGE B. RAY (*J. Gen. Physiol.*, 1923, 5, 469—477).—The rate of production of carbon dioxide by living and by dead *Ulva*, a green marine alga, in the presence of chloroform, has been investigated, and the influence of ferric sulphate and hydrogen peroxide determined. W. O. K.

**The Biological Action of Röntgen Rays. III.** EUGEN PETRY (*Biochem. Z.*, 1923, 135, 353—383).—Seed embryos submitted to the action of a number of oxidising agents are not thereby rendered more or less sensitive to Röntgen radiation. The only oxidising agent which confers greater sensitiveness is hydrogen peroxide. H. K.

**Chemical Constituents of Green Plants. XXIV. Citric Acid.** HARTWIG FRANZEN and FRITZ HELWERT (*Biochem. Z.*, 1923, 135, 384—415).—From a critical survey of the available literature on the occurrence of citric acid in plants, the authors conclude that the generally accepted view that citric acid is widely distributed is erroneous, as in many cases the identification is insufficient. H. K.

**Chemical Constituents of Green Plants. XXVI. Tartaric Acid.** HARTWIG FRANZEN and FRITZ HELWERT (*Biochem. Z.*, 1923, 136, 291—305).—A critical survey of the literature on the recorded occurrence of tartaric acid in eighty-two plants leads to the conclusion that tartaric acid only occurs with certainty in five,

*Vitis vinifera* (berries), *Tamarindus indica* (fruit), *Beta vulgaris* (unripe beet), *Acer saccharinum* (juice), and *Pyrus aucuparia* (berries). It also, probably, occurs in *Quercus pedunculata*. H. K.

**The Formation of Vitamin-A in Plant-tissues. II.** KATHARINE HOPE COWARD (*Biochem. J.*, 1923, 17, 134—144; cf. i., 1921, i, 837).—Light is necessary for the formation of vitamin-A in plant-tissues. Ultra-violet rays of the spectrum are not essential, and the formation of the vitamin can take place under the influence of electric light in the absence of sunlight. The process of vitamin-A synthesis can be carried on in the absence of carbon dioxide and of oxygen in the surrounding atmosphere, and is independent of the presence of chlorophyll in the plant. The presence of chloroform in the atmosphere, however, prevents the formation of the vitamin. Almost complete absence of calcium salts from the nutrient solution of a water culture of *Tradescantia* does not prevent the synthesis of vitamin-A in the leaves of the plant. S. S. Z.

**The Association of Vitamin-A with Lipochromes of Plant tissues.** KATHARINE HOPE COWARD (*Biochem. J.*, 1923, 17, 45—156).—Some lipochrome (generally carotene) is always associated with the vitamin in plant-tissues and consequently the presence of carotene, particularly carotene exposed to sunlight, suggests the presence of vitamin-A also. S. S. Z.

**Hydrocyanic Acid in Burmah Beans (*Phaseolus lunatus*).** F. CHARLTON (*Agric. Res. Inst. Pusa Bull.*, 140, 7 pp.).—The amount of hydrocyanic acid liberated by enzyme action in Burmah beans increases with the age of the bean. The elaboration of enzymes in the beans therefore probably continues after the normal ripening process is complete. H. C. R.

**Influence of Sulphur Dioxide on the Respiration of Phanerogams.** JULIUS STOKLASA [with J. ŠEBOR, V. ZDOBŮČEK, and V. NEKOLA] (*Biochem. Z.*, 1923, 136, 306—326).—As a result of comparative experiments on young pines, it is found that small quantities of sulphur dioxide cause a diminution of the carbon dioxide output. The larger the content of sulphur dioxide, the less the respiratory activity. The pine needles show at the same time a bleaching of the chloroplasts. H. K.

**The Mobilisation of Mineral Substances and of Nitrogen in the Bark and Wood in Spring Growth.** AUGUST RIPPPEL (*Biochem. Z.*, 1923, 135, 518—531).—During sprouting of shoots of *Sambucus nigra*, the potassium, phosphorus, and nitrogen are strongly mobilised, the magnesium and sodium to a lesser extent, and calcium, sulphur, and chlorine scarcely at all. The potassium content of the wood increased by 28% after sprouting. H. K.

**Walnut Oil.** KAZUO MATSUMOTO and YOSHISUKE UYEDA (*J. Chem. Ind. Japan*, 1922, 25, 1438—1440).—The fruit of the walnut (*Juglans Sieboldiana*) produced in the Prefecture of Ishikawa

gave 26.54% of kernel, from which 59.58% of oil was obtained by pressure. The oil is light yellow in colour and without odour, and shows the properties of a drying oil:  $d_{40}^{15}$  0.9332,  $n_D^{20}$  1.4800, acid value 0.68, Hehner value 92.3, saponification value 190.1, Reichert-Meissl value 0.62, and iodine value (Hübl) 150.8. K. K.

**Amino-acids of Feeding Stuffs. II. Amino-acids of Linseed Meal, Wheat Bran, Soja Beans, and Red Clover Hay.** T. S. HAMILTON, N. UYEL, J. B. BAKER, and H. S. GRINDLEY (*J. Amer. Chem. Soc.*, 1923, 45, 815—819; cf. A., 1923, ii, 93).—The amino-acid contents are tabulated of linseed meal, wheat bran, soja beans, and red clover hay, and of other foodstuffs already investigated, as estimated by the modified Van Slyke method previously described. [Cf. *J.S.C.I.*, 1923, 418A.] W. S. N.

**The Potassium-Nitrogen Ratio of Red Clover as Influenced by Potassium Fertilisers.** PAUL EMERSON and JOHN BARTON (*J. Amer. Soc. Agron.*, 1922, 14, 182—192).—The solubility of soil potassium, as indicated by absorption by the plant, is increased by applications of manure, acid phosphate, or combinations of both. The ability of red clover to take up potassium varies with the kind of compound supplied; for instance, the potassium of kainite is more easily absorbed than that of potassium chloride or sulphate. Calcium carbonate, when applied to an acid soil, appears not to affect the solubility of native soil potassium, but may possibly over-stimulate nitrate production. The potassium: nitrogen ratio is widened slightly by applications of lime, but narrowed by applications of manure or acid phosphate, or both, in the presence of lime.

CHEMICAL ABSTRACTS.

**Disappearance of Nitrates from Soil under Timothy Grass.** J. A. BIZZELL (*J. Amer. Soc. Agron.*, 1922, 14, 320—336).—The addition of sodium nitrate to timothy grass sod in early spring is followed by a rapid disappearance of the nitrate from the 20 cm. of surface soil; this disappearance is due only in part to the absorption of nitrogen by the growing crop. Leaching or denitrification apparently did not remove the nitrogen from the soil. Various organisms of the soil evidently transformed the nitrate into ammonia or into some form of organic combination.

CHEMICAL ABSTRACTS.

**Hydrogen-ion Concentration of the Soil and its Significance to the Vegetation, especially to the Natural Distribution of Plants.** CARSTEN OLSEN (*Compt. rend. Trav. Lab. Carlsberg*, 1923, 15, 1—166).—The object was to ascertain to what extent the natural flora of soils is affected by the hydrogen-ion concentration, and whether the effect is direct or caused by secondary changes. Botanical analyses of natural vegetation were compared with the reaction of the soils on which it grew. Individual species were found only to occur on soils having a definite range of  $pH$  values. Within this range is a narrower one in which the species appeared with the greatest average frequency. The number of

species and their frequency of occurrence is greatest on nearly neutral soils. Increased  $p_H$  value corresponds with a decrease in the number of species and their density. In water culture solutions, acid-soil plants grow best in media of  $p_H$  4; whilst plants characteristic of neutral and alkaline soils are favoured by nutrient solutions with  $p_H$  6—7. Typical acid-loving plants show poor growth and became chlorotic when grown in culture solutions which are only faintly acid. The theory that the apparent toxicity of acid soils (Hartwell and Pember, *Soil Sci.*, 1914, 6, 259) is due to soluble aluminium salts is not confirmed. Alkaline-soil plants were not injured by small amounts of aluminium salts. The acid-soil plants are not characterised by the power of utilising ammonium salts. Both acid- and alkaline-soil plants are nourished equally well by ammonium salts and by nitrates. Acid-soils cannot be differentiated from normal ones on account of their lack of nutrients. The flora of a rich acid-soil bear no resemblance to those of a poor alkaline soil. It is concluded that the hydrogen-ion concentration of a soil directly, and to a considerable extent, affects the nature of the vegetation growing upon it.

A. G. P.

**Influence of Hydrogen-ion Concentration on the Adsorption of Plant Food by Soil Colloids.** E. B. STARKEY and NEIL E. GORDON (*Soil Sci.*, 1922, 14, 449—457).—The adsorption by silica and ferric hydroxide gels of various plant nutrients was determined. The adsorption of cations was generally greater with increasing  $p_H$  values. Anions were adsorbed in the following order: phosphate, sulphate, nitrate. Acidity increased the adsorption of phosphate but the adsorption of sulphates and nitrates was scarcely affected by the reaction of the medium. Ferric hydroxide gel was a considerably more active absorbent than silica gel. Near the neutral point, slight changes in  $p_H$  values caused relatively large changes in the adsorption of potassium-ions.

A. G. P.

#### Factors Affecting the Soil Reaction. I. Soil-Water Ratio.

ROBERT M. SALTER and M. FRANCIS MORGAN (*J. Physical Chem.*, 1923, 27, 117—140).—The hydrogen-ion concentration of nine acid soils has been determined at soil-water ratios from 1:1 to 1:3125 by the hydrogen electrode method. The velocity of hydrolysis of sucrose by five of the same soils of soil-water ratio between 1:0.0894 and 1:625 has also been determined. Both methods of determination show that the hydrogen-ion concentration varies systematically with the soil-water ratio, the highest hydrogen-ion concentration occurring at high soil-water ratios, with a progressive decrease as the dilution is increased. In general, the changes in hydrogen-ion concentration at varying soil-water ratios agree with the distribution of hydrogen-ions between soil and solution, which could be expected if controlled by an adsorption mechanism. A slight tendency is noted with all soils to deviate from the theoretical adsorption values over a restricted range of dilution. With two of the nine soils examined, this deviation was sufficient to prevent the determination of a theoretical equation which would describe

the variation in hydrogen-ion concentrations observed. On the basis of the results obtained, it appears that the reaction of a soil is dependent mainly on the total dissociated acid present and to a lesser extent on the adsorptive capacity of the soil for hydrogen-ions and the soil-water ratio. It is urged that the soil-water ratio should be stated in all results on hydrogen-ion measurements of soils and that one of the ratios, 1:5, 1:25, or 1:125, should be chosen as a standard.

J. F. S.

**Relations Between the Active Acidity and Lime Requirement of Soils.** EDGAR T. WHERRY (*J. Wash. Acad. Sci.*, 1923, 13, 97—102).—A correlation coefficient is employed to express the relationship between soil acidity and lime requirement, based on the equation lime requirement =  $C \times (\text{Specific acidity} - 1)$ . (For "Specific acidity" see Wherry, *ibid.*, 1920, 9, 305.) Values of  $C$  are calculated from published data, and are shown to vary to so great an extent with soil type and treatment that no calculations of lime requirement from it seem practicable. The coefficient  $C$  is believed to be a measure of the adsorptive power of soils for the hydrogen-ion, and may be used as a basis for a rough classification of soils.

A. G. P.

**Catalytic Action of Soils.** SHIGERU OSUGI (*Ber. Ohara Inst. landw. Forsch.*, 1922, 2, 197—218).—The power of soils to decompose hydrogen peroxide would appear to be associated with humus, ferric compounds, and manganese compounds, although no relationship between catalytic power and the soil content of these substances was found. Soil catalysis was increased by coagulating agents and decreased by peptisation.

The reaction of the soil may influence its catalytic power directly, and also as a result of its effect on the physical state of the soil particles. The effect of bacteria on soil catalysis is small, and that of enzymes larger, but the organic and inorganic soil constituent are the most important factors.

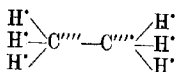

A. G. P.

**Adsorption of Plant Food by Colloidal Silica.** R. C. WILEY and NEIL E. GORDON (*Soil Sci.*, 1922, 14, 441—447).—The adsorption of various plant foods was determined by shaking with silica hydrosol and hydrogel. Negative adsorptions may be due either to the water being more strongly adsorbed than the dissolved salts, or to the fact that the water of hydration does not all act as a homogeneous solvent, or to lower concentrations existing in the finer capillaries. In general, metals are negatively adsorbed by both gel and sol. Nitrates and sulphates are negatively adsorbed to a slight degree. The phosphate radicle is positively adsorbed by the gel, and negatively by the sol. In the former case, more phosphate was adsorbed than the radicle with which it was associated, and, moreover, was extremely difficult to wash out.

A. G. P.

## Organic Chemistry.

**The Foundations of an Electronic Theory of Organic Chemistry.** A. M. BERKENHEIM (*J. Russ. Phys. Chem. Soc.*, 1917, 49, [ii], 1—181).—A theoretical paper in which an attempt is made to apply J. J. Thomson's and Stark's views of the structure of the atom to explain the reactions of carbon compounds. It is suggested that the neutral carbon atom acquires positive or negative polarity according to whether it parts with one or more electrons on becoming connected with other atoms or, conversely, acquires one or more electrons in the process; this polarity of the carbon atom then determines its reactions. Ethane is represented as

and acetylene as  $\text{H} \cdot \text{C}^{''''} - \text{C}^{''''} \text{H} \cdot$ ; a large number of organic reactions is discussed and shown to support the theory.

G. A. R. K.

**Low Temperature Tar. II.** FRANZ SCHÜTZ, WILHELM BUSCHMANN, and HEINRICH WISSEBACH (*Ber.*, 1923, 56, [B], 869—874; cf. this vol., i, 195).—The communication deals mainly with the components of the light oils which boil below 75°.

The isolation of the paraffin hydrocarbons is effected by treatment of the various fractions with concentrated sulphuric acid and examination of the unabsorbed and non-polymerised portions. The fraction, b. p. up to 10°, contains *n*-butane (4%), that of b. p. 15—35° contains methylbutane, b. p. 17—18° (2.4%), and *n*-pentane (5.1%). Methylpentane, b. p. 62—63° (18%), and *n*-hexane (24%) are, respectively, present in the fractions of b. p. 53° and 68—72°, whereas *n*-heptane (21%) and *n*-octane (1%) are found in those of b. p. 98—102° and 120—130°. The isolation of the paraffins from the fractions of higher boiling point is particularly difficult, since the aromatic hydrocarbons largely predominate. Heptane is possibly present in the benzene fraction, b. p. 77—78.5°.

The identification of the unsaturated hydrocarbons is effected by preliminary fractional distillation within very narrow limits, followed by treatment of the individual fractions with bromine and isolation of the bromides. Ethylene, propylene,  $\Delta^2$ -butylene,  $\Delta^3$ -butylene, and  $\Delta^2$ -pentene are thus shown to be present. *cyclo*-Pentadiene is shown to occur to the extent of 5—7% in the fraction, b. p. 40°, and is identified by conversion into dimethylfulvene, b. p. 154—155°.

The first runnings of the light oil contain acetaldehyde in addition to acetone, whilst methyl ethyl ketone and acetonitrile are present

in the benzene fraction. Methyl mercaptan and dimethyl sulphide are also found in the first runnings. The fraction, b. p. 20–40°, contains carbon disulphide in very small amount. H. W.

**Lignite Low Temperature Tar.** E. FROMM and H. ECKARD (*Ber.*, 1923, 56, [B], 948–953).—The low temperature tars obtained in rotary furnaces from two geologically similar lignites, termed, respectively, "Louise" and "Grefrath," obtained from the neighbourhood of Cologne have been investigated; they exhibit peculiar differences, which are possibly due to differences in botanical origin.

The neutral components of the "Louise" tar which are volatile with steam, have boiling points 140–240°, and the densities of the individual fractions increase regularly from 0.835 to 0.895. They appear to be mixtures of unsaturated hydrocarbons and oxygenated substances. The similarly obtained components of the "Grefrath" tar have b. p. 115–240°,  $d$  0.819–0.897, and give a portion, b. p. 115–160°,  $d$  0.823–0.832, which contains an ether and a terpene-like compound,  $C_{10}H_{18}$  or  $C_{11}H_{20}$ , b. p. 185°,  $d$  0.8659.

The neutral components of the "Louise" tar which are not volatile with steam consist of a mixture of paraffins which is separated by fractional distillation and subsequent crystallisation into the following individuals, which are assumed to belong to the normal series:  $C_{23}H_{48}$ , m. p. 46°;  $C_{24}H_{50}$ , m. p. 52°;  $C_{25}H_{52}$ , m. p. 57.5°;  $C_{26}H_{54}$ , m. p. 62°;  $C_{27}H_{56}$ , m. p. 69.6°;  $C_{28}H_{58}$ , m. p. 73°. The occurrence of the first member is remarkable, since only hydrocarbons with an even number of carbon atoms have been isolated previously from tars.

The basic portions of the "Louise" tar which are volatile with steam contain a yellowish-brown oil from which a benzoyl derivative, m. p. 36°, could be obtained in small amount, and pyridine which is identified as its additive product with mercuric chloride, m. p. 194°. The presence of pyridine in the similarly isolated fraction of the "Grefrath" tar could not be detected; by treatment of it with aqueous oxalic acid it was, however, found possible to isolate an oxalate, m. p. 177–178°, which is possibly derived from methylpyridine.

The acidic components which are volatile with steam contain only traces of carboxylic acids. The phenols are subdivided by fractional distillation under diminished pressure and analysed as their phenylurethanes. *m*-Cresol is the only substance of this class which could be identified with certainty; it is present in the "Grefrath" tar. Several phenols,  $C_6H_5OH$ , and a phenol,  $C_9H_{11}OH$ , are also present, the phenylurethanes of which are not apparently identical with any known compounds of this class. H. W.

**$\beta$ -Methyl- $\Delta^5$ -pentene.** H. VAN RISSEGHEN (*Bull. Soc. chim. Belg.*, 1923, 32, 144–150).—The hydrocarbon was prepared by condensation of acetic and butyric acids to methyl propyl ketone (pentane- $\gamma$ -one), which, on treatment with magnesium methyl

iodide, yielded a hexanol; this was then dehydrated by means of toluene-*p*-sulphonic acid. A second method, dehydration of  $\delta$ -methylbutyl alcohol, was also used.  $\beta$ -Methyl- $\Delta^2$ -pentene so obtained forms an additive product with bromine, and yields propaldehyde, acetone, and propionic acid on oxidation. It has b. p. 66.7—67.1°/760 mm., m. p. —134.75°;  $d_4^{20}$  0.7051,  $d_4^{15}$  0.69145,  $n_D^{15}$  1.4003,  $n_D^{15}$  1.4093,  $n_D^{15}$  1.4144,  $n_D^{15}$  1.4028. The bromo-derivative has b. p. 69.5—70.5°/14 mm., m. p. —54.49°;  $d_4^{15}$  1.6024,  $n_D^{15}$  1.5825,  $n_D^{15}$  1.50294,  $n_D^{15}$  1.51473,  $n_D^{15}$  1.52144,  $n_D^{15}$  1.506225. The action of chlorine on the hydrocarbon results in the formation of an additive product together with a more halogenated chloro-substitution compound and a derivative resulting from the fixation of one molecule of hydrogen chloride on the double bond.

H. J. E.

**Action of Bromine on Hydrocarbons.** B. K. MERESHOWSKY (*Annalen*, 1923, **431**, 113—132).—It is shown from the author's experiments and previous work on this subject that specific catalysts not only influence the rate and initial direction of halogenation, but also determine the simultaneous production of different end-products, if the reaction is allowed to continue; the production of polyhalogenated isomerides may therefore be selectively catalysed. The catalysts used are shown to form the following series, in the order of decreasing production of the more symmetrical isomeride: (1) pure bromine without a catalyst, (2) metallic iron, (3) metallic aluminium or aluminium tribromide, (4) ferric bromide. The substitution rules of Markovnikov, Städel, and V. Meyer are combined and extended as follows. (1) If the number of carbon atoms in the hydrocarbon is  $n$ , then, either with or without a catalyst at temperatures below 100°,  $n-1$  halogen atoms will become successively attached to carbon atoms on which substitution has not yet occurred. (2) If  $n-1$  atoms of the hydrocarbon already carry a halogen atom, a further halogen atom will enter partly on the remaining halogen-free carbon atom, and partly on that one of the other carbon atoms which carries the greatest number of hydrogen atoms. (3) Further substitution generally occurs on the carbon atom bearing the greatest number of hydrogen atoms. (4) Substitution always occurs in several directions, depending on the catalyst.

The action of pure bromine on propylene in the absence of a catalyst gives propylene bromide, 90%, and  $\alpha\beta\gamma$ -tribromopropane, about 4%. In the presence of metallic iron,  $\alpha\beta\gamma$ -tribromopropane and  $\alpha\alpha\beta$ -tribromopropane are formed in the proportion of 40 : 17; with ferric bromide or aluminium, the same compounds are produced in the ratio 8 : 33, and with aluminium bromide in the ratio 1 : 1. In the presence of aluminium a product of higher boiling point, 130—150°/20 mm., is also formed. The action of bromine on isobutylene in the absence of a catalyst at 45—50° leads mainly to the formation of dibromoisobutane, 45%, and of  $\alpha\beta\gamma$ -tribromoisobutane, m. p. —32°, b. p. 222—225°/75 mm. (Pogorschelsky, *A.*, 1905, i, 315), 44%, together with smaller amounts of tetra-

bromo-, pentabromo-, and hexabromo-derivatives. In the presence of metallic iron, the above is the only tribromo-derivative produced, but the use of ferric bromide leads to the formation of  $\alpha\alpha\beta$ -tribromoisobutane and  $\alpha\beta\gamma$ -tribromoisobutane in the ratio 31:11; the former gives  $\alpha\alpha$ -dibromoisobutylene,  $\text{CMe}_2\text{CBr}_2$ , the latter  $\alpha$ -bromo- $\gamma$ -acetoxy- $\beta$ -methylpropylene,  $\text{CHBr}\cdot\text{CMe}\cdot\text{CH}_2\cdot\text{OAc}$ , on treatment with potassium acetate. The same tribromo-derivatives are formed in the ratio 3:5 in the presence of aluminium or aluminium tribromide. Two tetrabromo-derivatives are found in the fractions of higher boiling point. (1)  $\alpha\alpha\beta\gamma$ -Tetrabromoisobutane, b. p. 134—136°/14 mm.,  $d_4^{20}$  2.45445, which is converted by heating with potassium acetate into  $\alpha\alpha$ -dibromo- $\gamma$ -acetoxy- $\beta$ -methylpropylene,  $\text{CBr}_2\cdot\text{CMe}\cdot\text{CH}_2\cdot\text{OAc}$ , b. p. 114°/16 mm.,  $d_4^{20}$  1.75070, which gives  $\alpha\alpha$ -dibromopropenylcarbinol,  $\text{OH}\cdot\text{CH}_2\cdot\text{CMe}\cdot\text{CBr}_2$ , on hydrolysis. (2)  $\alpha\beta\gamma\delta$ -Tetrabromoisobutane, m. p. 25°, b. p. 150—151°/14 mm.,  $d_4^{20}$  2.55953, the constitution of which is certain, since other possible tetrabromo-derivatives could not be produced from  $\alpha\beta\gamma$ -tribromoisobutane; moreover, the action of potassium acetate and acetic acid gives the bromo-ester,  $\text{CHBr}\cdot\text{C}(\text{CH}_2\cdot\text{OAc})_2$ , b. p. 136°/14 mm.,  $d_4^{20}$  1.45335, from which the glycol,  $\text{CHBr}\cdot\text{C}(\text{CH}_2\cdot\text{OH})_2$ , m. p. -80°, b. p. 158°/16 mm.,  $d_4^{20}$  1.69582, is produced by hydrolysis. Hexabromoisobutane, m. p. 93°, occurs in small amounts in the residue left after the more volatile halides have been distilled in steam. The constitution of  $\alpha\alpha\beta\gamma$ -tetrabromoisobutane is established by its formation by the addition of bromine in ethereal solution to the unsaturated dibromo-derivative,  $\text{CHBr}\cdot\text{CMe}\cdot\text{CH}_2\cdot\text{Br}$  (A., 1914, i, 508).  
W. S. N.

**Mechanism of the Reactions of Alkyl Halides.** ADOLF FRANKE and RUDOLF DWORZAK (*Monatsh.*, 1923, 43, 661—671).—The possibility of the intermediate formation of unsaturated compounds during the conversion of bromo- into hydroxy-derivatives, etc. (cf. A., 1914, i, 7), has suggested to the authors to study similar displacements of halogen attached to an asymmetric carbon atom, when, if an optically active derivative is obtained, no intermediate unsaturated compound can have been formed. Active secondary butyl bromide and iodide give an active *mercaptan* on treatment with alcoholic potassium hydrosulphide. The product is converted for purposes of identification, etc., into the mercury derivative, which is shown to be  $\text{C}_4\text{H}_9\text{S}\cdot\text{HgCl}$ , not  $(\text{C}_4\text{H}_9\text{S})_2\text{Hg}$ , the formula given to the corresponding inactive product by Reymann (A., 1875, 141). This author recorded a m. p. 188°, but the present authors obtain no evidence of melting at much higher temperatures.

Potassium hydrosulphide converts  $\alpha\gamma$ -dibromo- $\beta\beta$ -dimethylpropane into the corresponding *dithiol*, which with mercuric chloride gives the compound,  $\text{CMe}_2(\text{CH}_2\cdot\text{S}\cdot\text{HgCl})_2$ .

When optically active *sec*-butyl iodide is heated with aqueous sodium carbonate until it is converted into the alcohol, the latter is inactive. The bromide, on similar treatment, gives a slightly active alcohol.

The Labile Nature of the Halogen Atom in Organic Compounds. IX. The Electrical Conductivities and the Reduction of Derivatives of Nitroform. THOMAS HENDERSON, EDMUND LANGLEY HIRST, and ALEXANDER KILLEN MACBETH (T., 1923, 123, 1130—1137).

$\alpha\beta$ -Dinitroethane and the Action of Silver Nitrite on Ethylene Iodide. ALEXEI V. IPATOV (*J. Russ. Phys. Chem. Soc.*, 1917, 49, 297—303).— $\alpha\beta$ -Di-iodoethane is treated with silver nitrite by Demjanov's method and the mixture of  $\alpha\beta$ -dinitroethane and nitroethyl nitrite thus obtained fractionally distilled. Three fractions are obtained, the first of which, b. p. 70—72°/5 mm., is mainly unchanged  $\alpha\beta$ -di-iodoethane, the second, b. p. 70—78°/5 mm., is a mixture of the latter with nitroethyl nitrite and dinitroethane, whilst the third, b. p. 81—106°/5 mm., is mainly the latter. The  $\alpha\beta$ -dinitroethane thus obtained, b. p. 94—95°/5 mm.,  $d_4^{20}$  1.4597,  $n_D^{20}$  1.4488, forms a tetrabromo-derivative,  $C_2O_4N_2Br_4$ , yellow needles, m. p. 46—47°, and gives on reduction ethylenediamine, the hydrochloride of which sublimes without melting at 208°.

R. T.

The Examination and Dehydration of Methyl Alcohol by Means of Magnesium. NIELS BRERRUM and LÁSZLÓ ZECHMEISTER (*Ber.*, 1923, 56, [B], 894—899).—Clean magnesium reacts vigorously with absolute methyl alcohol at the atmospheric temperature giving magnesium methoxide and hydrogen. The rate at which the latter is evolved is greatly dependent on the water content of the alcohol, which is also indicated by the appearance of the mixture, since magnesium hydroxide is precipitated if water is present. The reaction is given a quantitative form by measuring the time necessary for the evolution of 5, 10, or 20 c.c. of hydrogen under standard conditions and reference to a table which is fully given in the original.

Magnesium is also very suitable for the preparation of anhydrous methyl alcohol. About 10 g. of the clean metal are placed in about a litre of methyl alcohol contained in a distillation apparatus. The reaction speedily becomes so vigorous that the alcohol is brought to its boiling point. When the metal has dissolved, the solution is kept gently boiling during several hours, after which the methyl alcohol is distilled, the first portion of the distillate being rejected. A single treatment usually suffices. It is advantageous to carry out the distillation in a current of dry air. The utility of magnesium is restricted to specimens of methyl alcohol which do not contain more than 0.5—1% of water, but it has the advantage over calcium that it does not introduce ammonia into the alcohol.

Magnesium methoxide,  $Mg(OMe)_2 \cdot 3MeOH$ , crystallises in rhombic plates. At 18° it dissolves in methyl alcohol to the extent of 0.9 mol. per litre.

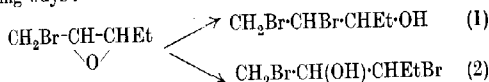

H. W.

Addition of Hydrogen to Acetylene Derivatives. IX. Addition of Hydrogen to Acetylenic  $\gamma$ -Alcohols. J. S. ZALKIND and (MILE) M. A. VILENKINA (*J. Russ. Phys. Chem. Soc.*, 1917, 49, 130—148).—It was observed (A., 1914, ii, 257) that if  $\beta$ -dimethyl- $\Delta^2$ -hexinene- $\beta$ -diol is reduced by the Sabatier method, using as

(2) Potassium ethyl sebacate,  $\text{CO}_2\text{Et} \cdot [\text{CH}_2]_{10} \cdot \text{CO}_2\text{K}$ , was electrolysed by the method of Brown and Walker (A., 1891, ii, 1192) to give *n*-hexadecanedicarboxylic ethyl ester,  $\text{CO}_2\text{Et} \cdot [\text{CH}_2]_{14} \cdot \text{CO}_2\text{Et}$  (as a by-product was obtained an acid, b. p. 248–249°, which was identified as  $\Delta^7$ -nonenoic acid,  $\text{CH}_3 \cdot \text{CH} \cdot [\text{CH}_2]_6 \cdot \text{CO}_2\text{H}$ , giving an ester boiling at 226–228° [Brown and Walker gave about 250° for the ester, which is incorrect]). The *n*-hexadecanedicarboxylic ester was reduced by sodium and amyl alcohol to the new glycol,  $\text{OH} \cdot \text{CH}_2 \cdot [\text{CH}_2]_{14} \cdot \text{CH}_2 \cdot \text{OH}$ , which forms white crystals, m. p. 92°, b. p. 238°/13 mm., and on gentle oxidation with permanganate gives the known acid,  $\text{C}_{18}\text{H}_{34}\text{O}_4$ , m. p. 118°. On treatment with sulphuric acid, a new oxide was obtained as a semi-solid, yellow mass, in amount sufficient to purify for analysis: it is probably *ac-oxido-octadecane*,  $\text{H}_3 \cdot [\text{CH}_2]_{12} \cdot \text{CH} \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2 \cdot \text{CH}_2$ , since on oxidation with dilute permanganate it yields an acid the silver salt of which, when analysed, gave figures approximating to those required for the salt of myristic acid,  $\text{CH}_3 \cdot [\text{CH}_2]_{12} \cdot \text{CO}_2\text{H}$ . F. A. M.

**Action of Organomagnesium Compounds on the Epibromohydrin of Ethylglycerol.** RAYMOND DELABY (*Compt. rend.*, 1923, 176, 1153–1156).—The action of organic magnesium halides on the epibromohydrin of ethyl glycerol is but little comparable with that on glycerol epibromohydrin, as in the case of both alkyl and aryl magnesium bromides the main reaction consists in the addition of the elements of hydrogen bromide to the epibromohydrin, and only traces of an aryl derivative are formed. The addition of hydrogen bromide might occur in either of the two following ways:

The compound (1) has already been obtained by the addition of bromine to ethylvinylcarbinol (this vol., i, 289) and in the present case it is exclusively the compound (2),  $\alpha\gamma$ -dibromopentan- $\beta$ -ol, b. p. 119–119.5°/23 mm., which is formed. The two compounds were differentiated by the preparation of the picrates of the corresponding tetramethyldiaminopentanol, by oxidation to the corresponding ketones, and conversion of the latter into semicarbazones. The  $\alpha\gamma$ -dibromopentan- $\beta$ -one, b. p. 85–100°/19 mm., reacted with 1 mol. of semicarbazide, giving a ketotriazine by elimination of one of the bromine atoms with a H of the  $\text{NH}_2$ -group. The substance melts at 115–117°. On the other hand, the  $\alpha\beta$ -dibromopentan- $\gamma$ -one reacts with 2 mols. and gives a semicarbazone-ketotriazine, m. p. 229–230°. G. F. M.

#### Some Derivatives of the Glycerol,

ROBERT LESPICHAU (*Compt. rend.*, 1923, 176, 1068–1070).—The oxide of the methyl ether of this glycerol having the constitution

$\begin{array}{c} \text{CH}_2 \\ \diagup \\ \text{O} \end{array} \text{CH-CH:CH-CH}_2\text{-OMe}$  was obtained by the action of chloroacetaldehyde on a mixture of magnesium ethyl bromide and methyl propargyl ether. The product was decomposed with acidified water, extracted with ether, and treated with potassium hydroxide, whereby polymerisation products of the aldehyde were resinified and the chlorohydrin was converted into the oxide. It has b. p. 75–76°/15 mm  $d_{20}^{25}$  1.024,  $n_D$  1.4573. By treatment with hydrogen chloride, it is converted into the *chlorohydrin*,  $\text{CH}_2\text{Cl-CH(OH)-CH:CH-CH}_2\text{-OMe}$ , b. p. 117.5–118.5°/12 mm.,  $d_{20}^{21}$  1.1717,  $n_D$  1.4866. Sodium methoxide converts it into the *ether*,  $\text{OMe-CH}_2\text{-CH(OH)-CH:CH-CH}_2\text{-OMe}$ , a liquid, b. p. 119–120°/12 mm.,  $d_{20}^{23}$  1.0508,  $n_D$  1.4608. The ethylene oxide is converted on boiling with water into the glycol ether,

$\text{OH-CH}_2\text{-CH(OH)-CH:CH-CH}_2\text{-OMe}$ ,  
 a thick liquid, b. p. 155–156°/12 mm.,  $d_{20}^{23}$  1.1274,  $n_D$  1.481.  
 Addition of 1 mol. of bromine gives the bromohydrin,  
 $\text{OH-CH}_2\text{-CH(OH)-CBr:CBR-CH}_2\text{-OMe}$ ,  
 a solid melting at 51–52°, b. p. 192°/11 mm. Treatment of this compound with hydrogen bromide at 100° causes demethylation, but the product was not isolated in a pure condition. G. F. M.

**The Preparation of Ethers from Primary Alcohols.** JEAN POPELIER (*Bull. Soc. chim. Belg.*, 1923, **32**, 179–194).—A study of the conditions necessary for the etherification of some primary alcohols in order to obtain a high yield of the corresponding ethers showed that this may be effected by means of a study of the binary mixtures of alcohol and water and the ternary mixtures of alcohol, ether, and water. From a knowledge of the boiling points of these mixtures and the composition of the vapour phase in each case, the preparation of the ethers may be effected with yields of about 90% by simple distillation of the alcohols with sulphuric acid. In general, the process is discontinuous, as adjustments in the composition of the mixture undergoing distillation must be made from time to time. The most suitable proportion of acid varies considerably, according to the alcohol used. Details are given of the application of the method to propyl, butyl, *isobutyl*, amyl, and *isoamyl* alcohols. Formation of unsaturated hydrocarbons may be obviated by working at a sufficiently low temperature.

H. J. E.

**The  $\alpha\alpha'$ -Dichlorodialkyl Sulphides.** FREDERICK GEORGE MANN and (SIR) WILLIAM JACKSON POPE (*T.*, 1923, **123**, 1172–1178).

**Crystal Structure of Basic Glucinum Acetate.** (SIR) W. H. BRAGG (*Nature*, 1923, **111**, 532).—X-Ray analysis shows that the molecule of basic glucinum acetate,  $\text{Gl}_2\text{O(C}_2\text{H}_3\text{O}_2)_6$ , is a perfect tetrahedron, the oxygen atom being at the centre, the glucinum atoms lying on lines from the centre to the corners, and each  $\text{C}_2\text{H}_3\text{O}_2$  group being associated in a symmetrical manner with the edges of the tetrahedron. The crystal structure is that of diamond, a molecule replacing each atom of carbon. A. A. E.

**The Addition of Hydrogen to Acetylenic Acids.** DAVID EMBYS WILLIAMS and THOMAS CAMPBELL JAMES (*Aberystwyth Studies*, 1922, 4, 197—207).—By reduction of phenylpropionic acid with hydrogen in presence of colloidal platinum, Paal and Hartmann obtained *allocinnamic* acid (A., 1909, i, 926) showing that *cis* addition had taken place. Experiments on the same lines with crotonic acid have given similar results, 63% of the theoretical yield of *allo-crotonic* and only 4% of ordinary crotonic acid being obtained. Reduction of acetylenedicarboxylic acid in the same manner, in the form of its normal potassium salt, gave, however, umaric acid without any trace of maleic acid. The addition thus takes place in the *trans* position, and supports the views of Michael A., 1918, i, 249) on the relation between the energy content of such systems and their stereochemical activity. When acetylenedicarboxylic acid is reduced with hydrogen and colloidal platinum in presence of less than two equivalents of alkali, the fumaric acid is further reduced to succinic acid almost as quickly as it is formed.

E. H. R.

**The Constitution of Elaeostearic [Elaeostearic] Acid.** I. VERCRUYSE (*Bull. Soc. chim. Belg.*, 1923, 32, 151—156; cf. Kametaka, T., 1903, 83, 1042; Majima, A., 1909, i, 204).—It has been shown that elaeostearic acid,  $C_{18}H_{32}O_2$ , contains two ethylenic linkings (Fokin, A., 1907, i, 10), and the author has effected oxidation with concentrated permanganate solution, obtaining valeric and azelaic acids, these two products accounting for fourteen of the carbon atoms in the chain. Further oxidation experiments with subsequent weighing of the carbon dioxide evolved showed that the remaining carbon was completely oxidised. Ozonisation of the acid confirmed this result, the products being 75% of the theoretical yield of azelaic acid, 50% of that of valeric acid, and a small quantity of succinic acid. The formula of elaeostearic acid is therefore  $CH_3(CH_2)_3CH:CH(CH_2)_2CH:CH(CH_2)_7CO_2H$ .

**The Labile Nature of the Halogen Atom in Organic Compounds. VIII. The Action of Hydrazine on the Halogen Derivatives of Acetoacetic and Benzoylacetate Esters and of Benzoylacetone.** ALEXANDER KILLEN MACBETH (T., 1923, 123, 122—1130).

**Chlorine Derivatives of Pyruvic Acid.** EFIM FILIMOVITSCH KLIMENKO (*J. Russ. Phys. Chem. Soc.*, 1917, 49, 290—293).—In view of the statement made by Seissl (A., 1889, 489), that the ester obtained by Klimenko (*Ber.*, 1870, 3, 465) from the product of the reaction between phosphorus pentachloride and pyruvic acid is not ethyl dichloropropionate but a mixture of the ethyl esters of monochloro- and dichloro-pyruvic acids, the latter acid is synthesised by the chlorination of pyruvic acid. *Ethyl dichloropyruvate* boils at 160—190°, whereas the ethyl dichloropropionate previously obtained is a crystalline solid, m. p. 115°. Seissl's views must therefore be considered to be incorrect.

**Ring-chain Tautomerism. V. The Effect of the gem-Dipropyl Grouping on the Carbon Tetrahedral Angle.** LESLIE BAINS and JOCELYN FIELD THORPE (T., 1923, 123, 1206—1214).

**Physical Properties of Maleic, Fumaric, and Malic Acids.** JOHN MORRIS WEISS and CHARLES R. DOWNS (*J. Amer. Chem. Soc.*, 1923, 45, 1003—1008).—Maleic anhydride has m. p. 52.6°; *i*-malic acid, m. p. 128.5—129°; maleic acid, m. p. 130—135°; fumaric acid, m. p. 284°; the solubility of these compounds in various common solvents has been determined and compared with previously recorded values. It is also shown that *i*-malic acid is less hygroscopic than citric and tartaric acids. The specific gravity of solutions of *i*-malic and maleic acids of various concentrations is shown graphically. W. S. N.

**Chromium Malate and Chromomalic Acid.** J. BARLOT and PANAITOPOL (*Bull. Soc. chim.*, 1923, [iv], 33, 306—311).—Chromium malate was obtained in less than 10% yield by dissolving chromium hydroxide in an aqueous solution of malic acid by the aid of heat, evaporating the solution, and purifying the product by successive precipitations from aqueous solution by means of acetone. To obtain an analytically pure product, the chromium hydroxide must be washed free from sodium, and the malic acid purified from potassium by precipitation of the latter as chloroplatinate. Quantitative yields were obtained by the action of a metallic malate on a solution of a chromium salt, and the best results from the point of view of isolating the product were given by acting on a solution of purified chromium sulphate with lead malate at 100°, filtering off the lead sulphate, removing the excess of lead in solution by treatment with hydrogen sulphide, and precipitating the chromium malate as small, anhydrous, greyish-green, hygroscopic crystals by addition of acetone. The anhydrous salt is soluble only with difficulty in water, but on evaporation of the solution a green, amorphous substance is obtained readily soluble in cold water. This is a hydrated substance of the composition  $2[(C_4H_4O_5)_3Cr_2] \cdot 13H_2O$ , which has acidic properties corresponding with the replacement of 5H, and salts are formed with metals, for example with lead, having the composition  $Pb_5[(C_4H_4O_5)_6Cr_4(OH)_5 \cdot 8H_2O]_2$ . These salts in analogy to the chromi-oxalates are termed chromimalates. From the green hydrated chromium malate, and from the chromimalates chromium is not precipitated by the usual reagents. G. F. M.

**Oxidation of Lignin Alcohol to Lignic Acid and the Occurrence of Lignic Acid.** J. GRÜSS (*Ber. Deut. bot. Ges.*, 1923, 41, 53—58; cf. this vol., i, 541).—The oxidation of lignin alcohol by means of hydrogen peroxide leads to *lignic acid*, isolated as the more soluble  $\alpha$ -copper salt,  $C_7H_{14}O_5Cu \cdot 5H_2O$ , and the less soluble  $\beta$ -copper salt. The former has been isolated from oak-wood attacked

by *Polyporus versicolor*, and from pine-wood attacked by *Trametes radiciperda*. A third copper salt has also been obtained from *mykolignic acid*, which is found in pine-wood infested by fungus; this acid gives *oxymykolignic acid* on oxidation by means of hydrogen peroxide. The copper salts are described in detail. W. S. N.

**Synthesis of Anemoninic Acid.** ATUSI FUJITA (*J. Pharm. Soc. Japan*, 1923, No. 492, 67—75).—Anemoninic acid,  $\text{CO}_2\text{H}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CO}\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{CO}\cdot\text{CH}\cdot\text{CH}\cdot\text{CO}_2\text{H}$ , has been synthesised from  $\delta$ -furylidenelevulic acid by Baeyer's method. The  $\delta$ -acid (10 g.), prepared by a somewhat modified method of Kehrer and Hofacker (A., 1897, i, 204), was dissolved in excess of sodium carbonate solution and reduced with 3% sodium amalgam (about 100 g.) to  $\delta$ -furfuryllevulic acid, white plates, m. p. 99°, the semicarbazone of which forms small white plates, m. p. 125°.  $\delta$ -Furfuryllevulic acid (4 g.) was dissolved in warm water (400 c.c.), to which bromine water (3.3 g. bromine) was added at a time. Then the mixture was mixed with moist silver oxide, prepared from 20.5 g. of silver nitrate, and warmed at 70° during three hours. After cooling, it was acidified with dilute hydrochloric acid, concentrated in a vacuum and extracted ten times with acetic ester, from which  $\alpha$ -anemoninic acid was obtained as a syrup containing some crystals. By treating with a small quantity of hydrochloric acid (20%), it was changed into the  $\beta$ -isomeride, colourless plates, m. p. 189°. K. K.

**Action of Molybdic Acid on the Rotatory Power of Tartaric and Malic Esters.** E. DARMOIS (*Compt. rend.*, 1923, 176, 1140—1142).—It has already been shown that molybdic acid causes a change in the rotatory power of tartaric and malic acids, and the subject was further investigated by studying the effect of molybdic acid in methyl and ethyl tartrates and malates in dilute aqueous solution. A progressive change in rotation occurred, the rate of which was greatly accelerated by an increase in temperature, but the final value attained was unaffected, as was also the dispersion. The rate of change in rotation and also the final value were dependent on the relative proportions of molybdic acid and ester. The addition of potassium hydroxide in amount less than one-fourth of the quantity required to form  $\text{K}_2\text{MoO}_4$  has no effect on the rate of variation of  $\alpha$ , but larger amounts cause a rapid acceleration of the change. Ammonium molybdate has a similar effect. With ethyl malate molybdic acid causes practically no change in rotation in the cold, but at 100° the change is rapid. It is concluded that the mutarotation is not due to a progressive esterification of the hydroxyl groups, but rather to a saponification of the esters.

G. F. M.

**Alkaline Hydrolysis of the Stereoisomeric Dimethyl Tartrates.** ANTON SKRABAL and LUDWIG HERMANN (*Monatsh.*, 1923, 43, 633—643).—A study of the relative rates of hydrolysis of methyl *d*- and *l*-tartrates, racemate, and *mesotartrate*, by sodium carbonate and by carbonate-hydrogen carbonate mixtures. An improved method for preparing the *d*-ester is described (cf.

Anschütz and Pictet, A., 1880, 876). It is shown that the two-stage hydrolysis of the *d*- and *l*-esters proceeds at the same rate, the ratio of the velocity constants,  $k_1$  and  $k_2$ , for the two stages, depending on the concentration of ester, being smaller if the ester concentration is increased. For 0.05 to 0.1 molar solutions of *d*-ester, at 25°,  $k_1=4.2 \times 10^{-2}$  and  $k_2=0.30 \times 10^{-2}$ ; for 0.005 to 0.01 molar solutions,  $k_1=6.06 \times 10^{-2}$  and  $k_2=0.31 \times 10^{-2}$ . Almost identical values for  $k_1$  and  $k_2$  were obtained for similar solutions of the *l*- and the *dl*-ester, whilst the *meso*-ester (0.01–0.005 molar) gave  $k_1=4.3 \times 10^{-2}$  and  $k_2=0.15 \times 10^{-2}$  (cf. A., 1920, ii, 239). E. E. T.

**Alkaline Hydrolysis of Diacetyl-*d*-tartaric [Diacetoxysuccinic] Acid and of its Methyl Ester.** ANTON SKRABAL and LUDWIG MEHR (*Monatsh.*, 1923, 43, 645–653).—The velocity of alkaline hydrolysis of diacetyl-*d*-tartaric acid and of its methyl ester have been investigated. In the case of the ester, the methyl groups hydrolyse more rapidly than the acetyl groups. In the two-stage hydrolysis of the methyl groups, the ratio of the velocity constants for the two stages is roughly 2:1. In the two-stage hydrolysis of the acetyl groups in the acid, the corresponding ratio is 3.5:1. E. E. T.

**Optical Rotation of Arabinic Acid and of the Alkali Arabinates.** MOISEI ABRAMOVITSCH RAKUZIN (*J. Russ. Phys. Chem. Soc.*, 1917, 49, 247–250).—Gum arabic is shown to contain potassium, magnesium, and calcium, and has  $[\alpha]_D -24.8^\circ$ . Pure arabinic acid prepared from this has  $[\alpha]_D -27.86^\circ$ , and not, as Scheibler states,  $-98.5^\circ$ . The lithium, ammonium, sodium, and potassium salts have  $[\alpha]_D -17.81^\circ$ ,  $-19.81^\circ$ ,  $-21.67^\circ$ , and  $-23.06^\circ$ , respectively,  $[\alpha]_D$ , as in previous cases, increasing with the atomic weight of the substituting metal. R. T.

***n*- $\alpha$ -Sulphobutyric Acid and its Optically Active Components.** H. J. BÄCKER and J. H. DE BOER (*Proc. K. Akad. Wetensch. Amsterdam*, 1923, 26, 79–82).—*n*- $\alpha$ -Sulphobutyric acid can be obtained by the action of ammonium sulphite on  $\alpha$ -bromobutyric acid and by sulphonation of ethylmalonic acid, but is best prepared by sulphonation of *n*-butyric acid with sulphur trioxide. The butyrylsulphuric acid formed in the cold changes into sulphobutyric acid on heating. The acid crystallises after a long time in a vacuum over phosphoric oxide in hard, very hygroscopic crystals, m. p.  $66^\circ$ , containing  $1\text{H}_2\text{O}$ . Aniline sulphobutyrate forms small, glistening plates, m. p.  $175^\circ$ , and the *p*-toluidine salt has m. p.  $163^\circ$ . When these salts are heated with an excess of the amine, the amide of the carboxylic acid is formed. Aniline butyranilide- $\alpha$ -sulphonate crystallises in concentrically grouped, feather-like needles, m. p.  $253$ – $256^\circ$ ; *p*-toluidine butyro-*p*-toluidide- $\alpha$ -sulphonate has m. p.  $260$ – $263^\circ$ , the corresponding *p*-anisidine compound  $242^\circ$ , and the *p*-phenetidine compound  $264$ – $266^\circ$ . When heated with aromatic *o*-diamines, sulphobutyric acid forms derivatives of benzimidazole. Benzimidazole-2-propylsulphonic acid,  $\text{C}_6\text{H}_4 \begin{smallmatrix} \text{N} \\ \diagup \text{C} \text{---} \text{CHEt} \text{---} \text{SO}_3\text{H} \\ \diagdown \text{NH} \end{smallmatrix}$ , from *o*-phenylenediamine, and methyl-

benzimidazole-2-propylsulphonic acid,  $C_6H_5Me \begin{smallmatrix} \text{N} \\ \diagup \diagdown \\ \text{NH} \end{smallmatrix} C \cdot CHEt \cdot SO_3H$ ,

from 3:4-diaminotoluene, are white, crystalline substances of low solubility and high m. p. with properties similar to those of taurine.

The resolution of  $\alpha$ -sulphobutyric acid was accomplished through the strychnine salt. *Strychnine d-sulphobutyrate* crystallises in small, glistening needles containing  $2H_2O$ . The d- and l-barium salts form long needles containing  $2\frac{1}{2}H_2O$ , whilst the r-salt forms small, glistening leaflets containing  $2H_2O$ . The direction of rotation of the barium salts is opposite to that of the free acids. The magnitude of rotation varies with the concentration. The molecular rotation of the barium salt for sodium light is  $32.2^\circ$  in a 24% and  $29.9^\circ$  in a 5% solution. The presence of barium chloride lowers the rotation.

E. H. R.

**The Second Dissociation Constant of Sulphoacetic and  $\alpha$ -Sulphopropionic Acids.** H. J. BACKER (*Proc. K. Akad. Wetensch. Amsterdam*, 1923, 26, 83—87).—Using the values of the first dissociation constants of  $\alpha$ -sulphoacetic and  $\alpha$ -sulphopropionic acids previously determined (this vol., i, 88), the values of the second dissociation constants have now been determined from the hydrogen-ion concentrations, measured colorimetrically, of the acid salts and of mixtures of the acid and neutral salts. The values found, which can only be regarded as approximations, are, at the ordinary temperature,  $\alpha$ -sulphoacetic acid,  $7.2$  to  $9.7 \times 10^{-5}$ ;  $\alpha$ -sulphopropionic acid,  $4.2$  to  $6.0 \times 10^{-5}$ . E. H. R.

**Viscosity of the Systems Water-Bromal and Chloral-Dimethylethylcarbinol.** NIKOLAI NIKOLAEVITCH EFREMOV (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 338—371).—Binary fusion, viscosity, and density diagrams are constructed for the systems bromal-water and chloral-dimethylethylcarbinol. For the former system, maxima exist in the fusion and viscosity diagrams at 50 mol. %, corresponding with the formation of bromal hydrate. The summit of the viscosity isotherms moves from 50 to 42.5 mol. % on changing the temperature from  $40^\circ$  to  $100^\circ$ , and a similar change occurs in the isotherms of the temperature coefficients of viscosity, indicating that some dissociation of the compound occurs at higher temperatures. The minimum boiling-point mixture contains 35—45 mol. % of bromal. Bromal hydrate and its mixtures with bromal or water readily lose water with rise of temperature, causing the separation of the liquid into two layers. The density curves for both the system and chloral-dimethylethylcarbinol exhibit at first a rapid and then a gradual rise up to 100% of the halogen compounds. The viscosity isotherms and temperature coefficient of viscosity curves of the latter system are similar in type to those of the former, and indicate the formation of an equimolecular compound similar in properties to chloral hydrate or ethylate.

R. T.

**Trimethylacetaldehyde** [ $\alpha\alpha$ -Dimethylpropaldehyde]. I. ADOLF FRANKE and HERMANN HINTERBERGER (*Monatsh.*, 1923, 43, 655—660).—The aldehyde is prepared as follows: *iso*Butyl

alcohol is passed, together with carbon dioxide, through a brass tube filled with brass turnings and heated at 500—550°, when it is converted into isobutyraldehyde. The latter is converted into  $\beta\beta$ -dimethylpropan- $\alpha\gamma$ -diol, from which  $\beta\beta$ -dimethylpropyl alcohol is prepared as previously described (A., 1914, i, 7), although better conditions are now detailed. By passing the vapours of the last-named alcohol through a hot tube (as before),  $\alpha\alpha$ -dimethylpropaldehyde was obtained, and has been studied from the point of view of its possible resemblance to benzaldehyde rather than to a typical aliphatic aldehyde.

When treated with a little concentrated sulphuric acid, it rapidly polymerises to give a trimeride (needles, m. p. 82°) which is distinct from a similar compound described by Richard (A., 1911, i, 6). When heated in alcoholic solution with potassium cyanide, the aldehyde gives a small quantity of an acid (needles, m. p. 223°), presumably of the benzilic acid type, and formed as a result of the alkaline properties of potassium cyanide. E. E. T.

**The Isomeric Trithioacetaldehydes.** FREDERICK GEORGE MANN and (SIR) WILLIAM JACKSON POPE (T., 1923, 123, 1178—1181).

**Preparation of the Homologues of Mesityl Oxide by the Action of Gaseous Hydrogen Chloride on Ketones.** C. V. GHEORGHIU (*Bull. Acad. Sci. Roumaine*, 1923, 8, 68—71).—An attempt to condense homologues of acetone yielded, in the case of a mixture of acetone with methyl ethyl ketone, mesityl oxide, methylmesityl oxide with a larger amount of  $\beta\gamma$ -dimethyl- $\Delta^2$ -pentene- $\delta$ -one and small quantities of  $\gamma$ -methyl- $\Delta^2$ -hexene- $\epsilon$ -one and  $\gamma\delta$ -dimethyl- $\Delta^2$ -hexene- $\epsilon$ -one. From methyl ethyl ketone,  $\gamma\delta$ -dimethyl- $\Delta^2$ -hexene- $\epsilon$ -one is the chief product. The yield in both cases is small owing to resinification. H. J. E.

**Syntheses of  $\alpha$ -Diketones by Means of Organo-zinc Derivatives.** E. E. BLAISE (*Compt. rend.*, 1923, 176, 1148—1150; cf. this vol., i, 181).—It has been shown previously that the condensation of zinc propyl iodide with oxalylbisoxymethyl chloride gives a mixture of the bisoxycycloacetatoxyisobutyrylates of propylglyoxal and of dibutyryl. After alcoholysis of the mixed products only the latter remains. This forms a crystalline substance, m. p. 55—80°, consisting of a mixture of the internally compensated and the racemic isomerides. They could only be separated by slow crystallisation from methyl alcohol, and mechanical separation of the two kinds of crystals formed. The pure substances melt at 72° and 82°, respectively, and boil at 168°/13 mm. Hydrolysis of the mixed isomerides by means of hydriodic acid was accompanied by reduction, and propyl *n*-butyl ketone was formed, b. p. 163°, giving a semicarbazone, m. p. 96°. Hydrolysis by means of a mixture of hydrochloric and acetic acids gave, however, dibutyryl in 60% yield. It is a yellow liquid, b. p. 61.5°/14 mm. The dioxime melts at 181—182°, and the disemicarbazone above 250°.

G. F. M.

**The Oxidation of Dextrose by Yellow Oxide of Mercury, and the Preparation of Gluconic Acid.** A. BLANCHETIÈRE (*Bull. Soc. chim.*, 1923, [iv], 33, 345–348).—Gluconic acid was obtained as its calcium salt in almost theoretical yield by the oxidation of a 10% solution of dextrose with yellow mercuric oxide in presence of calcium carbonate. After boiling for twenty-four hours, the liquid was filtered from the mercurous oxide and mercury formed, concentrated by evaporation on a water-bath, and mercury precipitation of the calcium salt induced by the addition of an excess of alcohol. The pasty mass which separates becomes crystalline on keeping for several days over sulphuric acid. It was further purified by recrystallisation from water and alcohol. It contains 1 mol. of water, which it retains somewhat tenaciously, desiccation at 70–80° in a vacuum being necessary for the production of the anhydrous salt.

G. F. M.

**Carbohydrate Sulphates. VI. Acetone [isoPropylidene] Compounds of Dextrose Sulphates.** HEINZ OHLE (*Biochem. Z.*, 1923, 136, 428–448; cf. A., 1922, i, 986, this vol., i, 441).—Purified diisopropylidenedextrose, treated in pyridine solution with chlorosulphonic acid in chloroform, yields the crystalline pyridine salt of diisopropylidene-dextrose sulphate; it has m. p. 163–164° and  $[\alpha]_D^{20}$  –21.9° in chloroform ( $c=2.9$ ). The sodium salt has  $[\alpha]_D^{20}$  –14.7° in water ( $c=3.27$ ). It forms a crystalline additive product with sodium acetate, having  $[\alpha]_D^{20}$  –13.4° and decomposing at 221–222°. The brucine salt melts at 248° and has  $[\alpha]_D^{20}$  –27.6° in water and –30.98° in chloroform. When recrystallised from alcohol, pyridine diisopropylidene-dextrose sulphate loses one molecule of acetone and yields pyridine isopropylidene-dextrose  $\gamma$ -sulphate, m. p. 134°,  $[\alpha]_D^{20}$  –13.5° in water. The sodium salt is amorphous and hygroscopic, but the barium salt crystallises with 5 molecules of alcohol and has  $[\alpha]_D^{20}$  –14° in water. On boiling an alcoholic solution of the pyridine salt for four hours, the sulphuric acid is removed quantitatively as ethylsulphuric acid, identified as its brucine salt, m. p. 200–201°,  $[\alpha]_D^{20}$  –29.7° in water, and crystallising with 3/4 mol. of alcohol. isoPropylidene-dextrose  $\gamma$ -sulphuric acid is reconverted into the diisopropylidene-dextrose by shaking the pyridine salt with an equal weight of copper sulphate in fifty volumes of acetone for thirty-six hours. isoPropylidene-dextrose-6-sulphuric acid, which was isolated either as its crystalline sodium salt, m. p. 157°,  $[\alpha]_D^{20}$  –9.88°, crystallising with  $\frac{1}{2}$  H<sub>2</sub>O, as its amorphous barium salt,  $[\alpha]_D^{20}$  –7.2° in water, or better as its crystalline strychnine salt, m. p. 178–182° (when dried), and N/10-sulphuric acid solution, it loses acetone and yields dextrose-6-sulphuric acid, identifiable as its brucine salt and identical with Soda's preparation (this vol., i, 441). Strychnine-dextrose-6-sulphate monohydrate crystallises well, but during crystallisation its initial rotation falls from –6.27° to –3.12°, whilst its final value remains at –0.7°. A discussion follows of the mechanism of combination

of acetone with dextrose. Evidence has been obtained of intermediate combination with hydrochloric and with sulphuric acids.

H. K.

**Extraction of  $\beta$ -Ethylgalactoside in the Presence of a Large Proportion of Reducing Sugars.** J. CHARPENTIER (*J. Pharm. Chim.*, 1923, [vii], 27, 368—371).—Galactose has been identified in the products of the hydrolysis of gum arabic by converting it into  $\beta$ -ethylgalactoside by means of emulsin (cf. Bourquelot and Bridel, A., 1920, i, 530). All attempts to extract the  $\beta$ -ethylgalactoside with ethyl acetate gave a product which was contaminated with a large proportion of arabinose. By the action of hydrocyanic acid, however, in the presence of a trace of ammonia the sugar is converted into a nitrile which is hydrolysed to the acid containing one atom of carbon more than the original sugar. This acid is completely precipitated by basic lead acetate, and the  $\beta$ -ethylgalactoside is recovered from the filtered solution. It was obtained as somewhat voluminous, transparent crystals, melting at 159—160° and giving  $[\alpha]_D -4.40^\circ$ .

W. T. K. B.

**The Acetone [isoPropylidene] Compounds of Xylose.** OLOF SVANBERG and KNUT SJÖBERG (*Ber.*, 1923, 56, [B], 863—869).—In a recent communication (Freudenberg and Svanberg, A., 1922, i, 1116), the preparation of diisopropylidene-xylose by the action of hydrogen chloride on a suspension of xylose in acetone has been described. The remarkable observations were made that a portion of the catalyst appears to pass into a non-ionised form (and to be lost subsequently during the distillation in a high vacuum) and that the diisopropylidene-xylose is very pronouncedly mutarotatory. The behaviour of the hydrogen chloride, however, is shown to be independent of the presence of xylose and to be due in all probability to the formation of an additive product with mesityl oxide or phorone; this is not very material in the cases of the preparation of crystalline isopropylidene sugars, but if, as in the present instance, the products must be purified by distillation, it may easily happen that the distillates are contaminated with hydrogen chloride. Actually, the observed mutarotation of the specimens of diisopropylidene-xylose is shown to be due to this cause and the consequent hydrolysis of the substance to mono-isopropylidene-xylose.

Pure diisopropylidene-xylose, b. p. 85—87°/0.5 mm.,  $[\alpha]_D^{25} +14.0^\circ$  (constant), is conveniently prepared in 80% yield by agitating xylose with a solution of concentrated sulphuric acid in acetone at the atmospheric temperature and subsequent neutralisation of the mixture with barium and calcium carbonates. The rapidity with which the sugar dissolves depends greatly on the purity and dryness of the solvent. The residues from the preparation of the diisopropylidene compound contain small amounts of mono-isopropylidene-xylose, colourless needles, m. p. 41—43°,  $[\alpha]_D^{25} -19.0^\circ$  in aqueous solution (2—4%). The latter compound is more conveniently prepared by the partial hydrolysis of diisopropylidene-xylose by very dilute hydrochloric acid at 18°, the course of the

change, which is unimolecular, being conveniently followed by polarimetric observation.

H. W.

**The Structure of Sucrose.** MAX BERGMANN (T., 1923, 123, 1277—1279).

**Investigation of the Mannan Present in Vegetable Ivory.** JOCELYN PATTERSON (T., 1923, 123, 1139—1149).

**Cellulose Xanthates.** R. WOLFFENSTEIN and E. OESER (*Ber.*, 1923, 56, [B], 785—787).—The action of sodium hydroxide solution (d 1.2) and carbon disulphide on different cellulose acetates which are soluble in acetone leads to the formation of a *cellulose xanthate*,  $C_6H_5(O\text{Na})_2(O\text{-C}\cdot\text{S}\cdot\text{SNa})_2$ , which, in contrast to the product derived from cellulose, appears to be derived from a parent substance containing five active hydroxyl groups. It is a dark brown, resinous material which more readily evolves carbon disulphide on exposure to moist air than does the sodium salt of the more usual cellulose xanthate. It gives salts with the heavy metals which are less stable than the corresponding compounds from alkali-cellulose.

H. W.

**"Hydrocellulose." A Summary of the Literature.** PERCY HERBERT CLIFFORD (*J. Text. Inst.*, 1923, 14, T.69—77).—A review of the literature dealing with the preparation and properties of "hydrocellulose." Seventy-one references are cited.

J. C. W.

**Polysaccharides. \*VIII. Lichenin.** P. KARRER and B. JOOS (*Biochem. Z.*, 1923, 136, 537—541).—Lichenin from *Cetraria islandica* is closely allied to cellulose. By acetolysis at 120°, it yields octa-acetylcellobiose, and with acetyl bromide at 40° yields acetobromocellobiose. Lichenin acetate is prepared like cellulose acetate, and has a similar rotation,  $[\alpha]_D^{20} -23.8^\circ$  (in chloroform + methyl alcohol, 9:1). It yields aceto-1:6-dibromoglucose on treatment with phosphorus pentabromide. Lichenin is soluble in dilute alkali and in hot water.

H. K.

**Lignin.** J. GRÜSS (*Ber. Deut. bot. Ges.*, 1923, 41, 48—52; cf. Klasen, A., 1920, i, 821; 1922, i, 324; Beckmann, Liesche, and Lehmann, A., 1921, i, 546; 1922, i, 233; Paschke, A., 1921, i, 772; 1922, i, 325).—The action of ethyl-alcoholic hydrogen chloride on wood, previously extracted by means of 4% sodium hydroxide solution and boiling water, gives a substance described as *lignin alcohol*,  $C_{28}H_{46}O_{10}$ , m. p. 160°, *vanadium* derivative,  $C_{28}H_{42}O_{10}V_2$ , a microcrystalline powder. Numerous colour reactions of lignin alcohol are described (cf. Crocker, A., 1921, , 839).

W. S. N.

**Lignin.** EMIL HEUSER and ARNE WINSVOLD (*Ber.*, 1923, 56, B], 902—909).—Lignin has been considered to be an aromatic compound, whilst, on the other hand, arguments have been advanced in favour of an aliphatic structure, such as that of the cellulose and pentosans of wood. In the authors' opinion, the chemical evidence available is insufficient at the present to enable a definite decision

between these alternatives to be made, but in the present communication a number of experiments are quoted the results of which point to the conclusion that the molecule of lignin contains a benzenoid nucleus with oxidisable side chains.

Treatment of lignin with molten potassium hydroxide has been shown previously to lead to the formation of protocatechuic acid, pyrocatechol, and oxalic acid, whereas cellulose under similar conditions gives large amounts of oxalic acid and small quantities of protocatechuic acid and pyrocatechol. The previous results may be summarised in the statement that lignin and cellulose behave differently towards molten potassium hydroxide, the former giving mainly aromatic compounds, the latter chiefly oxalic acid. If the treatment of lignin is effected in an atmosphere of hydrogen or nitrogen the production of oxalic acid is very greatly diminished whereas that of aromatic compounds, particularly pyrocatechol, considerably increased. The formation of pyrocatechol from lignin is doubtless a secondary change due to the further decomposition of protocatechuic acid primarily formed. The latter substance by itself requires a high temperature ( $360^{\circ}$ ) to effect the complete removal of carbon dioxide, but in the presence of potassium hydroxide the change occurs at  $240^{\circ}$ . If air is present, the yield of pyrocatechol is small (1–3%), but oxalic acid is formed in considerable quantity (14–16%). The displacement of the yields in favour of pyrocatechol can also be greatly influenced by the presence of iron, which doubtless acts catalytically. Protocatechuic and oxalic acids are not present in the product, so that the decomposition of the former is also accelerated by the catalyst. Actually, a part of the pyrocatechol which is produced also suffers further change under these conditions, since the yield of the substance is only 23% of the weight of lignin taken.

Protocatechuic acid is converted by molten potassium hydroxide at  $240$ – $280^{\circ}$  in the presence of air into pyrocatechol (2.5%) and oxalic acid (about 20%), whilst 70% of it remains unchanged. In an atmosphere of hydrogen, the yields are pyrocatechol (19%), oxalic acid (0%), unchanged protocatechuic acid (77%), whilst in the presence of iron and hydrogen they are pyrocatechol (26%) and unchanged protocatechuic acid (0%).

The behaviour of ligninsulphonic acid towards molten potassium hydroxide is generally similar to that of lignin prepared by Willstätter's method.

The communication concludes with an extended, adverse criticism of the method proposed by Schmidt (A., 1921, i, 912; 1922, i, 206; this vol., i, 274) for the estimation of lignin in wood (the results of which are not in harmony with those obtained by the customary methods) and of the introduction of the conception of "skeleton substance."  
H. W.

**Humic Acids. IV. Preparation and Properties of Artificial and Natural Humic Acids.** WILHELM ELLER (and, in part, H. SAENGER, K. WENZEL, H. SEILER, and H. PIEPER) [*Annalen*, 1923, 431, 133–161].—An extension of previous work on the

subject (A., 1920, i, 733). Phenols are oxidised in alkaline solution by exposure to the air, by addition of hydrogen peroxide, by addition of potassium persulphate, or by electrolysis. In respect to the humic acids to which they give rise, the phenols investigated fall into four classes. (1) Hydroxyquinol gives a humic acid,  $(C_7H_5O_3)_x$ , which is also produced from hydroxyquinol triacetate; methylquinol is converted into the homologue,  $(C_7H_5O_3)_x$ . (2) Pyrogallol is oxidised to a humic acid,  $(C_{10}H_7O_{11})_x$ ; if insufficient alkali or persulphate is used, purpurogallin and a *hexahydroxydiphenyl*, m. p.  $230^\circ$ , are formed, either of which gives the same humic acid on continued oxidation. It is not, however, possible to obtain a pure humic acid by the oxidation of phloroglucinol, its triacetate, its diethyl ether, or its carboxylic acid. (3) Salicylic acid, gentisic acid, and 2:4:2':4'-tetrahydroxydiphenyl, in contrast to the phenols of the previous classes, undergo oxidation with elimination of carbon dioxide and production of a humic acid containing 56.37–56.57% carbon, 2.49–2.58% hydrogen, for which no formula has yet been devised. (4) The oxidation of phenol, *o*-cresol, resorcinol, or 3:5:3':5'-tetrahydroxydiphenyl leads to a product of variable composition. Nevertheless, it is shown that the properties (*loc. cit.*) of any of these phenol-humic acids are the same as those of the natural humic acids.

It is known that humic acids decompose at  $80^\circ$  (A., 1921, i, 506); this is doubtless the reason why humic acids prepared from carbohydrates by previous workers vary in composition. Indeed, it is now shown that if the temperature of reaction does not exceed  $70^\circ$ , the action of 45–50% aqueous sulphuric acid on sucrose, lactose, or dextrose leads to the formation of a humic acid,  $(C_7H_5O_3)_x$  (cf. Bottomley, A., 1915, i, 648), the composition of which is constant. A homogeneous product is not, however, obtained by the action of sulphuric acid on cellulose. Humic acids from carbohydrates show slight differences in their solubility, when compared with natural humic acids or those derived from phenol. Moreover, both natural and phenol-humic acids absorb atmospheric oxygen when moistened with alkali hydroxide solution; when they are warmed to about  $100^\circ$  with phenylhydrazine carbamate, nitrogen is evolved. These reactions are not, however, given by humic acids derived from carbohydrates (cf. following abstract).

W. S. N.

#### Humic Acids. V. Action of Nitric Acid on Humic Acids.

WILHELM ELLER, HARRY MEYER, and HANS SAENGER (*Annalen*, 1923, 431, 162–177; cf. preceding abstract).—The similarity between the natural humic acids and those derived from phenols is shown to extend to their derivatives. The action of cold concentrated nitric acid on quinol-humic acid gives *seminitrohumic acid*,  $(C_{12}H_7O_8NO_2)_x$ , a brownish-red, amorphous, hygroscopic powder, which is soluble in water, but tends to form colloidal solutions; the aqueous solution has an acid reaction, but does not decompose alkali carbonates. A product identical in composition and properties is obtained by the action of cold concentrated nitric

acid on natural humic acid; the insoluble material formed in this reaction is held to be an adsorption-compound of the nitro-acid and inorganic salts. Seminitrohumic acid causes the elimination of nitrogen when warmed with phenylhydrazine carbamate at 70°; its aqueous solution gives an intense red coloration when warmed with potassium cyanide solution. The action of hot, concentrated nitric acid leads to the formation of oxalic acid, carbon dioxide, and hydrogen cyanide.

When quinol-humic acid is treated with boiling concentrated nitric acid, oxidation and nitration occur simultaneously, with formation of a yellow, amorphous, very hygroscopic powder, *nitrohydroxyhumic acid*, the composition of which varies. In contrast to nitrohumic acid, it is insoluble in alcohol.

When quinone is treated with boiling concentrated nitric acid, nitration and polymerisation both occur, the product, *nitroquinone-humic acid*, being a reddish-yellow, amorphous, hygroscopic powder the composition and properties of which are intermediate between those of nitrohumic acid and nitrohydroxyhumic acid. When it is heated with phenylhydrazine carbamate, nitrogen is evolved at 80°. It forms a colloidal aqueous suspension.

The product of the action of cold concentrated nitric acid on sucrose-humic acid is a faintly yellowish-brown, amorphous powder,  $(C_{21}H_{21}O_{14}N_2)_2$ , which is only stable to air and sunlight after drying; it is soluble in alkalis or ammonia, and in water, alcohol, or acetone when freshly prepared, or on warming. In contrast to the other humic acids described, it decolorises aqueous potassium permanganate solution.

W. S. N.

**Humic Acids. VI. Action of Chlorine on Humic Acids.** WILHELM ELLER, ERNST HERDIECKERHOFF, and HANS SAENGER (*Annalen*, 1923, **431**, 177—186).—The action of chlorine gas at 50—70°, in the absence of air and sunlight, on an aqueous suspension of quinol-humic acid gives a golden-yellow, infusible, amorphous powder, *chlorohumic acid*,  $C_{10}H_5O_6Cl_5$ , which, when heated, decomposes below 100°, more rapidly at higher temperatures. When chlorohumic acid is heated with phenylhydrazine carbamate, nitrogen is evolved at 70°. Since it forms true solutions in ether, phenol, or glacial acetic acid, the molecular weight can be determined; in the formation of chlorohumic acid it is suggested that the six-membered rings in humic acid (A., 1921, i, 506) become converted into five-membered rings. The action of chlorine under the same conditions on natural humic acid gives identically the same product, but from sucrose-humic acid a pale-yellow, amorphous powder, decomp. 150°  $(C_{21}H_{21}O_{13}Cl_4)_2$ , is produced the properties of which are compared with those of the other humic acids as follows. The chloro-derivative from sucrose-humic acid is incompletely soluble in alcohol, and insoluble in ether, phenol, or acetic acid; the chloro-acids from phenols or natural acids very readily form true solutions in these solvents. The chloro-acid from sucrose, is stable to boiling water; the other chloro-acids are immediately decomposed with elimination of carbon dioxide. The chloro-acids

from natural or phenol-humic acids are immediately decomposed by means of cold concentrated alkali hydroxide solution, whereas the acid derived from sucrose is stable.

W. S. N.

**Conversion of Alanine into Pyruvic Acid by the Direct Action of Oxygen.** L. J. SIMON and LÉON PIAUX (*Compt. rend.*, 1923, 176, 1227—1229).—Whilst oxidising agents convert alanine into acetaldehyde, carbon dioxide, and ammonia, the direct action of oxygen itself on a solution of the sodium salt in presence of small amounts of copper causes the formation of pyruvic acid to the extent of a maximum of about 8%, when 0.25 atom of copper is present for each molecule of alanine. With greater proportions of copper, the amount of pyruvic acid produced progressively decreases, and as this decrease is not due to the further oxidation of pyruvic acid, it is clear that two quite distinct reactions are involved, one giving rise to pyruvic acid, and the other to acetaldehyde. These results lend support to the suggestion of Neubauer and Fromherz that pyruvic acid is an intermediate product in the biochemical transformation of amino-acids into alcohols.

G. F. M.

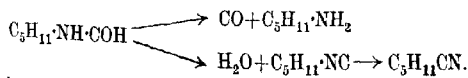

**The Optical Activity of Leucine and its Salts with Alkali Metals.** M. A. RAKUZIN (*J. Russ. Phys. Chem. Soc.*, 1917, 49, 32—93).—The molecular rotation of leucine salts is higher than that of the parent acid, and increases with the atomic weight of the metal. Thus  $[\alpha]_D$  for leucine in aqueous solution is  $-3.39^\circ$ ; lithium salt,  $-8.35^\circ$ ; ammonium salt,  $-10.34^\circ$ ; sodium salt,  $-20.21^\circ$ ; potassium salt,  $-23.22^\circ$  (cf. this vol., i, 494).

G. A. R. K.

**Optical Rotation of L-Aspartic Acid and its Alkali Salts.** M. A. RAKUZIN (*J. Russ. Phys. Chem. Soc.*, 1917, 49, 245—247).—The specific rotation of aspartic acid is found to be  $[\alpha]_D +3.63^\circ$ , not, as stated,  $+4.36^\circ$ . The lithium, ammonium, sodium, and potassium salts have  $[\alpha]_D -4.86^\circ$ ,  $-7.60^\circ$ ,  $-9.09^\circ$ , and  $-14.20^\circ$ , respectively,  $[\alpha]_D$  increasing with the atomic weight of the substituting metal.

R. T.

**Decomposition of the Formamides of Aliphatic Amines.** A. MAILHE (*Compt. rend.*, 1923, 176, 1159—1161; cf. this vol., i, 458).—The catalysis of the formyl derivatives of aliphatic amines over alumina at  $400-410^\circ$  proceeds in the same way as that of the corresponding aromatic compounds, with the formation of the amine and liberation of carbon monoxide. At the same time, a certain amount of nitrile is formed due to the dehydration of the amine. Thus isoamylformamide gave a mixture of isoamylamine and isovaleronitrile:

Catalysis over nickel at  $360^\circ$  furnishes carbon monoxide and dioxide, hydrogen, methane, olefines, and an alkaline condensate, b. p.

120—130°, consisting mainly of *isobutyronitrile* produced by the dehydrogenation of *isoamylamine*,

A portion of the *isoamylamine* is resolved into ammonia and *isoamylene*, which in its turn is decomposed further into methane, ethylene, etc. The hydrogenation of *isoamylformamide* over nickel at 200—210° gives a certain amount of secondary amine, *methylisoamylamine*, b. p. 108°, but the water produced hydrolyses some of the formamide to the primary amine, and the product is therefore a mixture of the two amines. G. F. M.

**Carbamide and Guanidine Derivatives of Aliphatic Sulphonic Acids.** RUDOLF ANDREASCH (*Monatsh.*, 1923, 43, 485—491).—A continuation of previous work (A., 1880, 877; 1883, 664). Sulphoacetylcarbamide,  $\text{NH}_2\cdot\text{CO}\cdot\text{NH}\cdot\text{CO}\cdot\text{CH}_2\cdot\text{SO}_3\text{H}$ , which cannot itself be obtained, forms well-defined salts. The potassium and ammonium salts are obtained by treating chloroacetylcarbamide with potassium and ammonium sulphite, respectively. If carbamide (10 g.), chloroacetic acid (16 g.), and phosphoryl chloride (15 g.) are heated together for three hours at 100°, a 75% yield of chloroacetylcarbamide results.

The potassium salt (needles, +1H<sub>2</sub>O) of *sulphoacetylmethylcarbamide*,  $\text{NHMe}\cdot\text{CO}\cdot\text{NH}\cdot\text{CO}\cdot\text{CH}_2\cdot\text{SO}_3\text{H}$ , is similarly obtained from chloroacetylmethylcarbamide (cf. Frerichs, A., 1899, i, 795, 796).

*Chloroacetylmethylcarbamide*, obtained from ethylcarbamide and chloroacetyl chloride, forms needles, m. p. 138°, and with potassium sulphite gives a solution from which the salt,

is obtained after evaporating in presence of barium acetate and extracting the potassium acetate with alcohol.

Potassium *sulphoacetylphenylcarbamide* is obtained from chloroacetylphenylcarbamide and potassium sulphite.

Chloroacetylguanidine hydrochloride, after treatment with potassium hydroxide and sulphite, yields *sulphoacetylguanidine*,

*s*-Diphenylcarbamide reacts slowly with chloroacetyl chloride to give a *chloroacetyl* derivative, m. p. 180°.

The successive actions of chloroacetyl chloride and ammonium sulphite on dicyanodiamidine sulphate give needles, m. p. 108°, probably the ammonium salt (+2H<sub>2</sub>O) of *sulphoacetyldicyanodiamidine*,  $\text{NH}_2\cdot\text{C}(\text{NH})\cdot\text{NH}\cdot\text{CO}\cdot\text{NH}\cdot\text{CO}\cdot\text{CH}_2\cdot\text{SO}_3\text{H}$ . Ammonium sulphite converts "bromural" (bromoisovalerylcarbamide) into the ammonium salt of *sulphoisovalerylcarbamide*,

*iso*Valerylcarbamide was isolated as well, but was probably present in the commercial bromural used. E. E. T.

**The Action of Potassium Cyanide on Monochloroamine.** W. F. SHORT (*Chem. News*, 1923, 26, 100—101).—A method is

described for the preparation of dicyanamide from a solution of hypochlorite and ammonia by the addition of potassium cyanide. It was removed from solution as the double silver salt,

from which the dicyanamide hydrochloride could be recovered. Cold hydrochloric acid converted the silver compound into a cyanocarbamide,  $\text{NH}_2\text{CO}\cdot\text{NH}\cdot\text{CN}$ . After precipitation of the silver by hydrogen sulphide, and concentration of the solution in a vacuum, an insoluble, amorphous polymeride of dicyanamide separated as a jelly-like mass.

W. E. G.

**Complex Thiocyanates of Tervalent Elements.** G. SCAGLIARINI and G. TARTARINI (*Gazzetta*, 1923, 53, i, 139—143).—The authors have successfully repeated Rosenheim and Cohn's attempts (A., 1901, i, 455) to prepare chromithiocyanates with the value of the ratio  $\text{Cr}:\text{SCN}$  other than 1:6, advantage being taken of Bjerrum's suggestion to effect the reactions in hot solutions containing an acid (A., 1922, i, 19). The hexathiocyanates of chromium are so stable that energetic chemical reagents are necessary to decompose them, and the chromithiocyanic acid from which they are derived is a resistant complex of pronounced acid character. Vanadium, iron, and aluminium form, however, less stable hexacid salts, which allow more readily of the gradual demolition of the complex anion. Thus a dilute solution of ammonium vanadithiocyanate contains at least a penta-aquo-salt, which may be rendered evident by conversion into the slightly soluble hexamethylenetetramine salt.

*Hexamethylenetetramine aquochromipentathiocyanate*,

forms violet crystals, and *hexamethylenetetramine chromihexathiocyanate*,  $(\text{C}_6\text{H}_{12}\text{N}_4\cdot\text{H})_3[\text{Cr}(\text{SCN})_6]$ , pale violet crystals.

*Hexamethylenetetramine aquovanadipentathiocyanate*,

forms brick-red crystals and the *aquoferripentathiocyanate*,  $(\text{C}_6\text{H}_{12}\text{N}_4\cdot\text{H})_2[\text{Fe}(\text{SCN})_5\text{OH}_2]$ , dark green, almost black crystals.

*Caffeine aquoferritritthiocyanate*,

forms mosaic gold, tabular crystals.

T. H. P.

**The Catalytic Reduction of Aliphatic Azines. II. Reduction of Dimethylketazine and isoButyraldazine in the Presence of Glacial Acetic Acid.** K. A. TAIPALE (*Ber.*, 1923, 56, [B], 954—962).—It has been found by the author (the communication will be published later) that dimethylketazine can be hydrogenated in the presence of platinum black to the corresponding symmetrical secondary hydrazine, and that the method can be extended to other aliphatic ketazines and aldazines, giving thus a method for the preparation of the difficultly accessible aliphatic hydrazohydrocarbons. Reduction, however, occurs very slowly, and the yields do not exceed 60% of those theoretically possible. It is found in the case of dimethylketazine that these disadvantages

can be largely avoided if the reaction is effected in glacial acetic acid solution. Under definite conditions, the change occurs with sufficient rapidity, and the yield of hydrazine attains 90%. The corresponding primary and secondary amines are formed as by-products and, in contrast to the action with the ketazine alone or in the presence of a neutral solvent, ammonia is produced in small amount. As the quantity of acetic acid is increased, the yields of the hydrazine diminish.

With *isobutyraldazine* the process is not so successful. The rapidity of hydrogenation is increased, but the yield of the hydrazine is diminished, whereas that of amines and ammonia is increased. In this case, also, increasing amounts of by-products are formed as the dilution of the solution increases. On the other hand, undue concentration of the solution causes gradual cessation of the change owing to the separation of solid acetates. The difficulty is most readily avoided by operating in alcoholic or ethereal solution with addition of a quantity of acetic acid which is approximately equivalent to the azine used.

The following compounds call for mention. *Diisopropylhydrazine dihydrochloride*,  $\text{CHMe}_2\cdot\text{NH}\cdot\text{NH}\cdot\text{CHMe}_2\cdot 2\text{HCl}$ , and the corresponding monohydrochloride, m. p. 203–204° after softening at 200°, and *monoperchlorate*, m. p. 145–146°. *Diisopropylsemicarbazide*,  $\text{NH}_2\cdot\text{CO}\cdot\text{NPr}^i\cdot\text{NHPr}^i$ , m. p. 103–104°. *Monobenzoyldiisopropylhydrazine*,  $\text{NHPr}^i\cdot\text{NBzPr}^i$ , m. p. 44·5°. *Diisobutylhydrazine dihydrochloride*,  $\text{CHMe}_2\cdot\text{CH}_2\cdot\text{NH}\cdot\text{NH}\cdot\text{CH}_2\cdot\text{CHMe}_2\cdot 2\text{HCl}$ , and the corresponding monohydrochloride have m. p. 175° when heated rapidly. The *monoperchlorate*, m. p. 159° (decomp.), when rapidly heated, and the *dibenzoyl* derivative, small needles, m. p. 79–80°, are described. *Diisobutylsemicarbazide* crystallises in hexagonal plates, m. p. 132°.

*Diisobutylamine chloraurate* forms yellow crystals, decomp. 199–200°. H. W.

[No reference is made to the papers by Lochte, Bailey, and Noyes, A., 1922, i, 328; this vol., i, 26.]

**Bismuth Cacodylate.** P. CLAUSMANN (*Bull. Soc. chim.*, 1923, [iv], 33, 447–448).—A crystalline bismuth cacodylate of the composition  $(\text{AsMe}_2\text{O}_2)_3\text{Bi}\cdot 8\text{H}_2\text{O}$ , was obtained by dissolving the theoretical amount of bismuth oxide in a hot concentrated aqueous solution of cacodylic acid, filtering, and allowing the salt to crystallise. It forms colourless, hexagonal crystals, m. p. 82°. The whole of the water of crystallisation is not eliminated even at 120°, and above this temperature decomposition occurs. The salt is not so readily hydrolysed as the salts of bismuth with mineral acids. A similar compound cannot be obtained by double decomposition between a bismuth salt and an alkali cacodylate.

G. F. M.

**An Electrolytic Method for the Preparation of Mercury Dimethyl.** J. LEWIS MAYNARD and HENRY C. HOWARD, jun. (*T.*, 1923, 123, 960–964).

**Further Experiments on the Catalytic Dehydrogenation of Hexahydroaromatic Hydrocarbons.** N. ZELINSKY (*Ber.*, 1923, 56, [B], 787—788).—*o*-Dimethylcyclohexane is almost completely dehydrogenated to *o*-xylene when passed three times over platinum black at 300—310°; under similar conditions at 310°, *m*-dimethylcyclohexane yields *m*-xylene quantitatively. Four successive passages of *p*-dimethylcyclohexane over palladium black at 310° gives *p*-xylene in 96% yield, whereas menthane is largely transformed into *p*-cymene by two successive treatments at 300—305°. H. W.

**The Preparation of Aromatic Chloromethyl Derivatives.** G. BLANC (*Bull. Soc. chim.*, 1923, [iv], 33, 313—319).—Chloromethyl derivatives of aromatic hydrocarbons were obtained, in most cases in good yield, by the action of hydrogen chloride on trioxymethylene, or, more conveniently, 40% formaldehyde solution, and the hydrocarbon in presence of zinc chloride at about 60°. Thus from benzene an 80% yield of benzyl chloride together with *p*-dichloromethylbenzene were obtained. With larger quantities of zinc chloride and a more slowly conducted reaction, considerable amounts of diphenylmethane were obtained. From toluene, 1-methyl-4-chloromethylbenzene was prepared in a similar manner, whilst *m*-xylene gave 1:3-dimethyl-4-chloromethylbenzene, b. p. 115°/15 mm., and 1:3-dimethyl-4:6-dichloromethylbenzene, m. p. 93°. From ethylbenzene *p*-chloromethylethylbenzene was obtained, b. p. 95—96°/15 mm., and cumene gave a 75% yield of *p*-chloromethylisopropylbenzene, b. p. 100°/14 mm. Cymene was converted into 1-methyl-2-chloromethyl-4-isopropylbenzene, b. p. 120°/12 mm., identified by conversion into the corresponding aldehyde, b. p. 128°/15 mm., and oxidation of the latter with silver nitrate to 1-methyl-4-isopropylbenzoic acid, m. p. 69°. The condensation with naphthalene was carried out in presence of light petroleum as a diluent, and a good yield of 1-chloromethylnaphthalene, a colourless liquid having an irritating action on the skin, and boiling at 145—146°/6 mm., was obtained. G. F. M.

**The Influence of Nitro-groups on the Reactivity of Substituents in the Benzene Nucleus. VII. Reactions of 2:5- and 4:5-Dinitro-*m*-xylenes.** KATHLEEN IBBOTSON and JAMES KENNER (*T.*, 1923, 123, 1260—1268).

**The Cryoscopy of Diphenyl in Acetic Acid.** A. BERLANDE (*Bull. Soc. chim.*, 1923, [iv], 33, 466—468).—Experiments on the cryoscopic determination of the molecular weight of diphenyl using glacial acetic acid as solvent are described. The cryoscope employed was not hermetically sealed, and consisted of a stoppered test-tube immersed in an ice-bath, and the stirring was affected by means of the thermometer. The results were too low when the concentration of the solution was such that the freezing-point depression was less than about 0.5°, owing to the progressive hydration of the solvent, which itself caused a lowering of the freezing point of two- to three-hundredths of a degree in ten to

fifteen minutes and only when the depression caused by the diphenyl was sufficiently great to render this negligible, were approximately accurate results obtained. G. F. M.

**Röntgen Ray Spectroscopy of Organic Compounds.** KARL BECKER and HERTA ROSE (*Z. Physik*, 1923, **14**, 369—373).—The following parameters have been determined from crystals of the respective organic substances by X-ray analysis: dibenzyl,  $a:b:c = 2.082:1:1.211$ ,  $\beta = 119^\circ$ ; stilbene,  $a:b:c = 1.077:1:1.415$ ,  $\beta = 118^\circ 40'$ ; benzil,  $a:c = 1:1.652$ ; triphenylmethane,  $a:b:c = 1.140:1:0.578$ ; triphenylcarbinol,  $a:c = 1:0.534$ ; mannitol,  $a:b:c = 1.275:1:0.562$ ; sucrose,  $a:b:c = 1.225:1:0.920$ ,  $\beta = 105.74^\circ$ . The respective numbers of molecules in the unit cell and the corresponding calculated values of the densities are: dibenzyl, 2, 1.185; stilbene, 4, 1.246; benzil, 3, 1.415; triphenylmethane, 3, 1.103; triphenylcarbinol, 6, 1.234; mannitol, 2, 1.555; sucrose, 2, 1.574. In the case of stilbene, the value of  $a$  deduced from X-ray measurements is one half that deduced from goniometric measurements. In the respective cases of triphenylmethane, triphenylcarbinol, and mannitol, the following ratios were found between the respective axial lengths as determined by X-ray and goniometric measurements:  $a$ , 2:1;  $c$ , 3:4;  $a$ , 2:1.

J. S. G. T.

**Dinitronaphthalenes.** V. VESELÝ and K. DVOŘÁK (*Bull. Soc. chim.*, 1923, [iv], **33**, 319—333).—The preparation of the following hitherto inaccessible or unknown dinitronaphthalenes is described: 1:6-Dinitronaphthalene was obtained from 1-nitro-6-aminonaphthalene by replacing the amino-group successively with the diazonium group, and the nitro-group according to the method recently described (A., 1922, i, 690). It melted at  $161-163^\circ$ , and was identical with the compound prepared by Graebe and Drews (A., 1884, 1036). 1:7-Dinitronaphthalene was similarly obtained from 1-nitro-7-aminonaphthalene. It forms small, yellow crystals, m. p.  $156^\circ$ . In like manner 1:4-dinitronaphthalene was obtained from 1-nitro-4-aminonaphthalene. It forms small needles, m. p.  $129^\circ$ . The same reaction applied to 1-nitro- $\beta$ -naphthylamine gave only a diazo-oxide, but 1:2-dinitronaphthalene was obtained from *ar*-1:2-dinitrotetrahydronaphthalene (one of the nitration products of "tetralin") by bromination with 2 mols. of bromine, and heating the dibromo-derivative at  $180^\circ$ , when 2 mols. of hydrogen bromide were eliminated with formation of 1:2-dinitronaphthalene, which forms long, slightly brown needles, m. p.  $158^\circ$ . The hitherto very inaccessible 1:3-dinitronaphthalene was prepared in a similar way from *ar*-1:3-dinitrotetrahydronaphthalene. The partial reduction of 1:6- and 1:7-dinitronaphthalenes with alcoholic stannous chloride resulted in each case in the reduction of the  $\alpha$ -nitro-group, and 6-nitro- $\alpha$ -naphthylamine, red needles m. p.  $167^\circ$ , and 7-nitro- $\alpha$ -naphthylamine, red needles, m. p.  $121-122^\circ$ , were isolated from the respective reaction products. Their acetyl derivatives form yellow crystals melting at  $232-233^\circ$  and  $206-207^\circ$ , respectively. By diazotisation the former naphthyl

mine was converted into 6-nitro- $\alpha$ -naphthol, yellow needles, m. p. 79°. Partial reduction of the above two dinitronaphthalenes with ammonium sulphide, on the other hand, led to the reduction of the  $\beta$ -nitro-group, and formation of 5-nitro- $\beta$ -naphthylamine, and 8-nitro- $\beta$ -naphthylamine, m. p. 104–105°, respectively. The 1:2- and 1:3-dinitronaphthalenes did not behave in a perfectly analogous fashion. Stannous chloride reduced the  $\alpha$ -nitro-group of the 1:3-compound giving 3-nitro- $\alpha$ -naphthylamine, m. p. 136–137°, acetyl derivative, m. p. 255°, but the  $\beta$ -nitro-group of the 1:2-compound is attacked with formation of 1-nitro- $\beta$ -naphthylamine, m. p. 126–127°. Ammonium sulphide reduces 1:3-dinitronaphthalene mainly to the same 3-nitro- $\alpha$ -naphthylamine, together with a small amount of the 4-nitro- $\beta$ -naphthylamine, red needles, m. p. 95°, acetyl derivative, 237–238°. The decomposition of the diazonium salt of 3-nitro- $\alpha$ -naphthylamine gave 3-nitro- $\alpha$ -naphthol, yellow needles, m. p. 167–168°. With 1:2-dinitronaphthalene, ammonium sulphide gave only tarry products. The nitro-group in 1:2-dinitronaphthalene is very mobile, and was replaced by numerous other groups, for example, on boiling with sodium hydroxide 2-nitro- $\alpha$ -naphthol, m. p. 127–128°, was formed. Alcoholic ammonia caused the replacement of the nitro- by the amino-group, with formation of  $\beta$ -nitro- $\alpha$ -naphthylamine, m. p. 41–42°, and on boiling with aniline 2-nitro-1-anilinonaphthalene, orange crystals, m. p. 110–111°, was produced. G. F. M.

**The Crystalline Structure of Anthracene.** (Sir) W. H. RAE (Proc. Physical Soc., 1923, 35, 167–169).—The dimensions of the crystal unit of anthracene have been determined, and the major length of the molecule is found to lie along the  $c$  axis. The differences between the lengths of the  $c$  axis for naphthalene and anthracene is 2.5, which corresponds exactly with the width of the benzene ring. The calculated specific gravity is 1.255, which is in agreement with an experimental determination of this constant. The crystals of naphthalene and anthracene show great similarities; the same planes are in each case the best reflectors, and it is only in the length of the  $c$  axis that there is any great difference. The unit contains two molecules in each case, and since the symmetry number is four, a molecule in the crystal must possess a twofold symmetry. This symmetry has been confirmed by the results.

W. E. G.

**Compounds of Picric Acid with Hydrocarbons.** NIKOLAI EFREMOV (J. Russ. Phys. Chem. Soc., 1918, 50, 373–421).—Binary fusion diagrams are constructed for mixtures of picric acid with various substances. At 50 mol. % formation of the following picrates occurs: Acenaphthere picrate, m. p. 160.8°; acenaphthylene picrate, m. p. 165.3°; phenanthrene picrate, m. p. 132.8°; and  $\beta$ -Chloronaphthalene picrates, m. p. 125.7° and 81.5°, respectively;  $\alpha$ - and  $\beta$ -bromonaphthalene picrates, m. p. 130° and 115°, respectively;  $\alpha$ -benzyl-naphthalene picrate, m. p. 97°, and tene picrate, m. p. 120.9°. Unstable picrates are also formed with

stilbene, transition point, 92.8°, and  $\alpha$ -nitronaphthalene, transition point, 54.7°. Nitroacenaphthene, diphenyl, dibenzyl, diphenylmethane, and triphenylmethane do not form picrates. R. T.

**Compounds of Picryl Chloride with Hydrocarbons.** NIKOLAI N. EFREMOV (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 421—440).—Binary fusion diagrams are constructed for mixtures of picryl chloride with various hydrocarbons and with picric acid. Equimolecular compounds form in every case with the former, whilst with the latter solid solution, but not compound formation is observed. The following compounds were obtained: Anthracene picryl chloride, m. p. 141.6°; acenaphthene picryl chloride, m. p. 113.2°; acenaphthylene picryl chloride, m. p. 109.4°; retene picryl chloride, m. p. 53.5°; naphthalene picryl chloride, m. p. 91.2°; phenanthrene picryl chloride, m. p. 82.4°, and fluorene picryl chloride, m. p. 64.6°. R. T.

**Compounds of Picramide with Hydrocarbons.** NIKOLAI N. EFREMOV (*J. Russ. Phys. Chem. Soc.*, 1918, 50, 441—459).—Binary fusion diagrams are constructed for mixtures of picramide with various hydrocarbons and with picric acid. In the latter case, no compound formation occurs, the components forming solid solutions up to 16% of picric acid and 11.5% of picramide. The following equimolecular compounds are formed: Naphthalene picramide, m. p. 168.8°; anthracene picramide, m. p. 158.8°; phenanthrene picramide, m. p. 160.2°; acenaphthene picramide, m. p. 195.4°; retene picramide, m. p. 125.1°; and an unstable equimolecular compound, transition point, 127.5°, exists for fluorene. R. T.

**Some Reactions of Tetranitroaniline.** CECIL WHITEFIELD DAVIES and THOMAS CAMPBELL JAMES (*Aberystwyth Studies*, 1922, 4, 213—216).—Tetranitroaniline does not form compounds with hydrocarbons in dry benzene or acetone solution. With phenol, there is a slight colour change but only with  $\beta$ -naphthol was a definite compound obtained,  $C_6H(NO_2)_4 \cdot NH_2 \cdot C_{10}H_7 \cdot OH$ , deep red needles, beginning to decompose at 110°, m. p. 140°. With primary amines, tetranitroaniline rapidly condenses with elimination of the 3-nitro-group. With aniline, 2:4:6-trinitro-3-aminodiphenylamine is formed, orange-yellow crystals, m. p. 188°. *o*-Toluidine gives 2:4:6-trinitro-3-aminophenyl-*o*-tolylamine, dark red crystals, m. p. 200°; 2:4:6-trinitro-3-aminophenyl-*m*-tolylamine forms brick-red crystals, m. p. 181°, and 2:4:6-trinitro-3-aminophenyl-*p*-tolylamine, orange crystals, m. p. 220°. 2:4:6-Trinitro-3-aminophenyl- $\beta$ -naphthylamine forms bright red crystals, m. p. 212°; from acetone it forms bright yellow crystals containing 1 mol. of acetone which are lost at 70°. When trinitroaniline is warmed with *n*-amyl alcohol, 2:4:6-trinitro-3-aminophenyl amyl ether is obtained, yellow crystals, m. p. 168°. Trinitro-*m*-phenylenediamine is formed when tetranitroaniline is warmed with aqueous ammonia. E. H. R.

**Separation of *o*- and *p*-Nitroacetanilides.** KENKICHI MATSUO and the KÔRÔ SEIYAKU KABUSHIKI KAISHA (Japan. Pat. 3523).—The nitration product of acetanilide is a mixture of about 70% *p*-nitroacetanilide and 30% of the ortho-isomeride. When the mixture is treated with hot water of about 80°, the ortho-isomeride dissolves, whilst the para-isomeride remains insoluble. By filtering, subsequent treatment with hot water if necessary, and washing with hot or cold water, the para-compound, m. p. 208°, is isolated almost quantitatively. The ortho-compound, m. p. 90–93°, is obtained from the mother-liquor and washings by cooling. Formerly it was considered that the para-isomeride is liable to decomposition by treatment with hot water in the presence of acid; the author, however, finds that this compound is stable towards hot water even in the presence of an acid, but the ortho-compound is decomposed to some extent into *o*-nitroaniline by treatment with hot water for a long time in the presence of an acid. K. K.

**The Action of Ferrous Chloride on the Hydrochlorides of some Aromatic Amines.** WILLIAM MURDOCH CUMMING (*J. Soc. Chem. Ind.*, 1923, 42, 166–168t).—The addition of ferrous chloride solution to solutions of the hydrochlorides of certain aromatic amines causes the precipitation of the hydrochlorides, without the formation of double salts. *o*- and *p*-Toluidine hydrochlorides crystallise in a variety of forms according to the conditions of crystallisation, and all these modifications were obtained by using ferrous chloride as precipitant, but after keeping in the mother-liquors for two days the various forms of the ortho-compound were almost completely converted into the rhombic form, and of the para-compound into the rhombohedral form, which modifications appear therefore to be the most stable forms of the hydrochlorides. The phenylenediamine hydrochlorides were not precipitated by ferrous chloride, except when an excess of concentrated hydrochloric acid was present. Ferrous chloride precipitates anhydrous benzidine monohydrochloride from solutions of the dihydrochloride, but from *o*-toluidine dihydrochloride solutions it precipitates a dihydrochloride crystallising with  $1\frac{1}{2}$  mols. of water. Both these salts are much less soluble in water than the normal dihydrochlorides. G. F. M.

**The Effect on the Reaction between Halogenonitrohydrocarbons and Aniline of Different Substituents in the Latter.** B. LINKE (*Ber.*, 1923, 56, [B], 848–851).—The velocity of reaction between chloronitrohydrocarbons and substituted anilines, occurring in accordance with the general scheme,  $2\text{PhNH}_2 + \text{C}_6\text{H}_4\text{ClNO}_2 = \text{NH}_2\text{Ph.HCl} + \text{NO}_2\text{C}_6\text{H}_3\text{NHPh}$ , has been investigated in alcoholic solution by determining the hydrochloric acid liberated after definite intervals of time as silver chloride. 4-Chloro-1-nitrobenzene, 4-chloro-1:3-dinitrobenzene, and 2-chloro-1:3:5-trinitrobenzene have been used on the one hand, and *o*-, *m*-, and *p*-nitro-, chloro-, bromo-, and iodo-anilines, the aminophenols, toluidines, phenylenediamines, aminobenzoic acids, aminobenzenesulphonic acids in addition to *p*-phenetidine, on the other.

The reactivity of the amines is diminished by the presence in them of iodine, bromine, chlorine, nitro-, sulphonic, or carboxylic groups, the effect of the two latter being less pronounced than that of the other four. The action of the substituent is least marked when it is in the meta-position to the amino-group, and most marked in the ortho-position. With regard to the other substituents investigated (OH, Me, and  $\text{NH}_2$ ), the most pronouncedly restrictive action is observed, as in the previous cases, when they are in the ortho-position, but the least action when they are in the para-position. The action of the amino-group is less marked than that of any other substituent.

The following compounds have been incidentally prepared: 2-Iodo-2':4'-dinitrodiphenylamine, golden-yellow, fibrous aggregates, m. p. 164—165°; 3-Iodo-2':4'-dinitrodiphenylamine, orange-coloured, rhombic crystals, m. p. 135°; 4-Iodo-2':4'-dinitrodiphenylamine, orange-coloured crystals, m. p. 185°; 2-Iodo-2':4':6'-trinitrodiphenylamine, orange-coloured, rhombic needles, m. p. 206°; 3-Iodo-2':4':6'-trinitrodiphenylamine, golden-yellow platelets, m. p. 150—152°; 4-Iodo-2':4':6'-trinitrodiphenylamine, golden-yellow, fibrous aggregates, m. p. 196°; 2-Chloro-2':4':6'-trinitrodiphenylamine, orange-coloured, rhombic crystals, m. p. 160—161°; 2-Bromo-2':4':6'-trinitrodiphenylamine, small, orange-coloured, rhombic leaflets or needles, m. p. 187—189°; 2-Methyl-2':4'-dinitrodiphenylamine, red, microcrystalline needles, m. p. 158—159°; 3-Methyl-2':4':6'-trinitrodiphenylamine, carmine-red aggregates, m. p. 119°.

H. W.

**The Mutual Replacement of Ammonia and Aniline in Amino-derivatives of Triphenylmethane.** PAVEL IVANOVITCH PETRENKO-KRITSCHENKO and A. GANDELMAN (*J. Russ. Phys. Chem. Soc.*, 1917, 49, 413—417).—Triphenylmethylaniline,  $\text{NHP}(\text{C}_6\text{H}_5)_3$ , is converted by heating in a sealed tube with alcoholic ammonia into triphenylmethylaniline, which can be reconverted into the former substance by heating with excess of aniline. Triphenylmethylcarbinol cannot be an intermediate product in these reactions, as on similar treatment with ammonia or aniline these substances are not produced. Triphenylmethylaniline can be more easily converted into triphenylmethylaniline by boiling with a solution in acetic acid of ammonium acetate. The reverse reaction does not, however, appear to take place. Triphenylmethylcarbinol, when treated in this way with ammonium or aniline acetate, gives fair yields of the corresponding amines.

R. T.

**Oxidations and Reductions Caused by Salts of Uranium under the Influence of Light. Antioxygen Action of Phenols.** JULES ALOY and VALDIGUÉ (*Compt. rend.*, 1923, 176, 1229—1231).—Oxidations and reductions brought about by uranium compounds under the influence of light are closely related to the changes which the uranium salt itself undergoes. Thus when alcohol or dextrose is added to a 1% solution of uranium acetate, the former is oxidised and the latter reduced to the violet oxide,  $\text{U}_3\text{O}_8 \cdot 2\text{H}_2\text{O}$ . If, in addition, methylene-blue is added to the above solution, the

dextrose is oxidised and the methylene-blue reduced, the uranium salt playing the rôle of an oxido-reducing catalyst. Aldehydes and the lower fatty alcohols can all be similarly oxidised, and the progress of the reaction can be followed by the reduction of the uranium acetate or of methylene-blue. The phenols, although readily oxidisable in ordinary circumstances, behave anomalously, owing to the antioxygen character of these substances, and they are neither oxidised themselves nor do they permit the oxidation of other substances to proceed. A red coloration is produced on adding the uranium compound to the phenol solution, but no other apparent change occurs. The solution does, however, contain a certain amount of uranous salt and the violet oxide can be precipitated from it by heating at  $100^{\circ}$ . G. F. M.

**Binary Systems of  $\alpha$ - and  $\beta$ -Forms of Chloroacetic Acid with Phenols.** IV. EFISIO MAMELI and GLAUCO COCCONI (*Gazzetta*, 1923, 53, i, 149—158; cf. A., 1913, ii, 571).—With the various phenols examined, neither the  $\alpha$ - nor  $\beta$ -form of chloroacetic acid forms additive compounds, the two acids behaving as acids of medium strength.

The fusion curve, and the position of the eutectic, for the systems phenol- $\beta$ -chloroacetic acid and *o*-cresol- $\beta$ -chloroacetic acid agree with those given by Kendall (A., 1916, i, 599) for the corresponding systems containing the  $\alpha$ -form of the acid. Data are given also for the binary systems formed by each of these acids with *m*- and *p*-cresols,  $\alpha$ - and  $\beta$ -naphthols, thymol, and guaiacol. T. H. P.

**Action of Organo-magnesium Compounds on Amino-phenols.** E. PUXEDDU (*Gazzetta*, 1923, 53, i, 99—105).—The action of magnesium ethyl bromide on 3-amino-*p*-cresol or amino- $\beta$ -naphthol differs from that on a compound containing an amino- or a phenolic group alone. In either case, gas is generated, two molecules of the Grignard reagent reacting with one molecule of the aminophenol, probably with formation of an additive compound,  $\text{OH}, \text{MgEtBr}$

pound of the type   $\text{NH}_2, \text{MgEtBr}$ . When treated with acetyl chloride, these products yield the corresponding diacetyl derivatives.

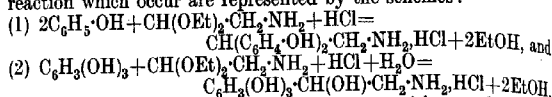

The acetyl derivative of 3-acetyl-amino-*p*-cresol,  $\text{OAc} \cdot \text{C}_6\text{H}_3\text{Mc} \cdot \text{NHAc}$ , forms crystals, m. p.  $157^{\circ}$ . T. H. P.

**Imino-aryl Ethers. II. The Thermal Decomposition of *N*-Arylaryliminoaryl Ether Hydrochlorides.** ARTHUR WILLIAM CHAPMAN (T., 1923, 123, 1150—1155).

**Nitro-derivatives of *m*-Cresol.** GEORGE PHILIP GIBSON (T., 1923, 123, 1269—1277).

**The Reaction of Aminoacetals with Phenols and Phenolic Ethers.** O. HINSBERG (*Ber.*, 1923, 56, [B], 852—857).—The introduction of the groups  $-\text{CH}_2\text{CH}_2\text{NH}_2$  or  $-\text{CH}(\text{OH})\text{CH}_2\text{NH}_2$  into the aromatic nucleus is of considerable importance in pharmacological chemistry. It can be effected by allowing aminoacetal or its *N*-alkylated substitution products to react with phenols

or phenolic ethers in the presence of hydrochloric or acetic and sulphuric acids as condensing agents. The two main types of reaction which occur are represented by the schemes:

The former reaction generally predominates with monohydroxy-, the latter with polyhydroxy-phenols, but its course can be altered in either case by suitable adjustment of the experimental conditions.

$\beta$ -Amino- $\alpha$ -di-4-hydroxyphenylethane,  $CH(C_6H_4\cdot OH)_2\cdot CH_2\cdot NH_2$ , is prepared by the action of concentrated hydrochloric acid at  $100^\circ$  on a mixture of aminoacetal and phenol. It crystallises in colourless needles, which are stable towards air, m. p.  $105^\circ$ ; the hydrochloride, a colourless, hygroscopic mass, and the chloroplatinate, brownish-yellow needles, are described.  $\beta$ -Amino- $\alpha$ -di-4-hydroxy-2-methyl-3-isopropylphenylethane, from aminoacetal and thymol, forms colourless needles, m. p.  $220^\circ$ ; it yields a hydrochloride (+ $2H_2O$ ), colourless needles.  $\beta$ -Amino- $\alpha$ -di-2-hydroxy-1-naphthylethane, colourless needles, m. p.  $124^\circ$ , and its hydrochloride, colourless needles, are described.

Methylaminoacetal reacts with two molecular proportions of pyrocatechol in the presence of concentrated hydrochloric acid at the atmospheric temperature to give  $\beta$ -methylamino- $\alpha$ -di-o-dihydroxyphenylethane,  $(C_6H_3(OH)_2)_2CH\cdot CH_2\cdot NHMe$ , colourless needles, m. p.  $143^\circ$ , which yields a hydrochloride, colourless needles, sparingly soluble in hydrochloric acid. If, however, molecular proportions of methylaminoacetal and pyrocatechol are heated with hydrochloric acid and water in a sealed tube at  $100^\circ$ , r- $\beta$ -methylamino- $\alpha$ -hydroxy- $\alpha$ -o-dihydroxyphenylethane,  $(HO)_2C_6H_3\cdot CH(OH)\cdot CH_2\cdot NHMe$ , is obtained; the free base is unstable when exposed to air, but yields a stable hydrochloride which is freely soluble in water. r- $\beta$ -Amino- $\alpha$ -hydroxy- $\alpha$ -o-dihydroxyphenylethane is obtained as the hydrochloride from pyrocatechol and aminoacetal. Pyrogallol and aminoacetal yield the unstable r- $\beta$ -amino- $\alpha$ -hydroxy- $\alpha$ -trihydroxyphenylethane (the hydrochloride crystallises in colourless needles). r- $\beta$ -Amino- $\alpha$ -hydroxy- $\alpha$ -carboxytrihydroxyphenylethane,

is isolated as the hydrochloride from the product of the action of gallic acid on aminoacetal.

$\beta$ -Amino- $\alpha$ -diphenylethane, which could not be obtained in the crystalline condition, is the main product of the action of aminoacetal on phenetole in the presence of sulphuric and acetic acids.  $\beta$ -Methylamino- $\alpha$ -bis-o-dimethoxyphenylethane is non-crystalline; it gives a hydrochloride, small, colourless needles, m. p.  $102^\circ$ .  $\beta$ -Amino- $\alpha$ -hydroxy- $\alpha$ -trimethoxyphenylethane, from aminoacetal and pyrogallol trimethyl ether, gives a hydrochloride, colourless crystals, m. p.  $187^\circ$ , and a chloroplatinate, pale yellow plates.  $\beta$ -Amino- $\alpha$ -bistrimethoxyphenylethane hydrochloride forms large, colourless crystals, m. p.  $199^\circ$ ; the free base has little tendency towards crystallisation.

H. W.

**Catalytic Ammonolysis of  $\beta$ -Naphthol and Chlorobenzene in the State of Vapour.** A. M. HOWARD and ALEXANDER LOWY (*J. Ind. Eng. Chem.*, 1923, 15, 397—401).— $\beta$ -Naphthol and chlorobenzene vapours mixed with ammonia were passed at definite temperatures over various contact materials. For  $\beta$ -naphthol, alumina was the best catalyst, and yields of 90—95% of  $\beta$ -naphthylamine were obtained under suitable conditions. The activity of the catalyst increased very rapidly from 400° to an optimum temperature range of 430—450°, and the best yields of the primary amine were obtained when the  $\beta$ -naphthol was heated at 191—193° in the vapour of boiling dimethylaniline, and a slow stream of ammonia gas was bubbled through. If the rate of flow of the vapour mixture was too great, equilibrium was not attained during its passage over the catalyst, and lower yields resulted. Using pure ammonia, the catalyst did not depreciate materially in activity during a run of sixteen hours' duration. About 5% of  $\beta\beta$ -dinaphthylamine was obtained as a by-product. Experiments were conducted with titania and thoria as catalysts, but the results were inferior to the above. In the experiments with chlorobenzene, some conversion to aniline was effected with reduced nickel or iron catalysts at 380° and 450°, respectively, but the catalysts were soon poisoned, and the original yields of about 7% rapidly fell off to mere traces. Reduced cobalt, copper, and platinum black gave still less satisfactory results. G. F. M.

**Boric Acid Compounds of some Organic Substances containing more than One Hydroxyl Group. Boron as a Quinquevalent Element.** P. H. HERMANS (*Proc. K. Akad. Wetensch. Amsterdam*, 1923, 26, 32—42).—By the action of boric acid on  $\beta\beta$ -dimethylpentane- $\beta\delta$ -diol, a compound is obtained which crystallises with great facility, m. p. 100—102°, and must have the formula  $\text{CH}_2 \begin{smallmatrix} \text{CMe}_2\text{O} \\ \text{CMe}_2\text{O} \end{smallmatrix} \text{B}\cdot\text{OH}$ . It has a saffron-like odour, and is

a weak acid no stronger than boric acid. It was supposed from the latter observation that the strong acids which are formed by addition of many polyhydroxy-compounds to boric acid solutions must have a different constitution from the above compound. In confirmation of this view, weakly acidic boric acid compounds similar to the above were obtained from  $\beta\delta$ -dimethylhexane- $\beta\delta$ -diol and pinacone. Evidence of the formation of compounds with trimethylene glycol, ordinary glycol, and *cis*-cyclohexane-1:2-diol was also obtained, but the compounds could not be crystallised. All these compounds appear to be partly split up into their components in aqueous solution. In the case of the *cis*-cyclohexane-1:2-diol boric acid compound, a crystalline potassium salt was obtained. This has an alkaline reaction and the potassium can be titrated quantitatively in presence of methyl-orange. A dipotassium derivative of this compound was also obtained. Crystalline potassium salts of the boric acid compounds of *cis*-hydrindene-1:2-diol, *cis*-cyclopentane-1:2-diol, *cis*-tetrahydronaphthalene-1:2-diol, and -2:3-diols were also obtained, but they could not always be obtained free from potassium hydroxide on account of their high

solubility in water and in alcohol. These compounds provide a method for separating *cis*- from *trans*-cyclic-1 : 2-diols, as the latter do not give such compounds.

The crystalline potassium salt of pyrocatecholboric acid prepared by Böeseken, Haefen, and Obreen (A., 1918, i, 219) has been analysed again, as its composition was uncertain. It is now found to be  $C_{12}H_8O_4BK$  and the only plausible structure is  $\left[ C_6H_4 \begin{array}{c} \diagup O \diagdown \\ \diagdown O \diagup \end{array} \right]_2 BK$ .

The boron is here quinquivalent or, from another point of view, has the co-ordination number four. Although this salt has an alkaline reaction, the potassium cannot be titrated quantitatively; pyrocatecholboric acid is therefore a stronger acid than the other diol compounds described above. It is probable that other complex acids stronger than boric acid have a structure similar to that proposed for pyrocatecholboric acid. Free *pyrocatecholboric acid* can be obtained by heating the aniline salt in a vacuum, and can be purified by sublimation in a vacuum at 200°.

The boric acid compound of *cis*-cycloheptane-1 : 2-diol (cf. Derr, A., 1922, i, 651) forms an oil with a saturated solution of boric acid. On addition of aniline to the oil, it crystallises, forming an unstable aniline salt,  $C_{20}H_{38}O_4NB$ . This appears to be *aniline di-cis-cycloheptane-1 : 2-diolborate*. Scheibe's potassium borodicitrate and Jahn's zinc borodisalicylate are also probably derivatives of quinquivalent boron. The structure of these compounds is further discussed by Böeseken (this vol., ii, 406). E. H. R.

#### Ethylene and Trimethylene Ethers of Dihydroxybenzenes.

I. MORITZ KOHN and FRANZ WILHELM (*Monatsh.*, 1923, 43, 545—555).—Molecular amounts of ethylene bromide and aqueous potassium hydroxide when refluxed with a large excess of resorcinol yield *di-resorcinol ethylene ether*,  $C_6H_4(O-C_2H_4-OH)_2$ , in fair yield as colourless, thin needles, m. p. 163°; the *benzoyl* derivative has m. p. 115—116°. With methyl sulphate and potassium hydroxide the *dimethyl ether*,  $C_6H_4(O-C_2H_4-OMe)_2$ , m. p. 61—63°, is formed, which is identical with the product obtained from resorcinol monomethyl ether and ethylene bromide in presence of sodium ethoxide. In a similar manner, trimethylene bromide refluxed with aqueous potassium hydroxide and resorcinol in large excess yields *di-resorcinol trimethylene ether*,  $C_6H_4(O-C_3H_4-OH)_2$ , long needles, m. p. 118°; *benzoyl* derivative, m. p. 97—98°. With methyl sulphate and potassium hydroxide it yields the dimethyl ether,  $C_6H_4(O-C_3H_4-OMe)_2$ , m. p. 39—41°, identical with the product from resorcinol monomethyl ether and trimethylene bromide in presence of sodium ethoxide. Ethylene bromide and aqueous potassium hydroxide refluxed with a large excess of pyrocatechol yield, however, only the cyclic ethylene ether,  $C_6H_4O_2C_2H_4$ , previously obtained by Vorländer (A., 1895, i, 17), and not the unknown bisdipyrocatechol trimethylene ether. Using trimethylene bromide, however, *dipyrocatechol trimethylene ether* is readily obtained in rhombic needles [ $\alpha$ :  $\beta$ :  $\gamma$ :  $\delta$  = 0.5047 : 1 : 0.6178], m. p. 123—125°, benzoyl derivative, m. p. 91—93°. On methylation, it yields a dimethyl ether identical with Gattermann's diguaiacol-trimethylene ether, obtained from

guaiacol and trimethylene bromide in presence of sodium ethoxide, m. p. 107—109° (111—112° ?) (A., 1908, i, 35). Quinol in large excess when refluxed with aqueous alkali hydrate and ethylene dibromide or trimethylene dibromide yields, respectively, Vorländer's diquinol ethylene ether and the new substance, *diquinol trimethylene ether*, m. p., respectively, 222—24° (Vorländer 219—220°), and 142—144°. The *ethylene* derivative forms a *dimethyl ether*, m. p. 148—150°, and a *benzoyl* derivative, m. p. 186°; the *trimethylene* derivative forms a *dimethyl ether*, m. p. 84—85°, and a *benzoyl* derivative, m. p. 138—139°. The methyl ethers are identical with the products obtained from quinol monomethyl ether and ethylene dibromide or trimethylene bromide, respectively, in presence of sodium ethoxide. F. A. M.

**Ethylene and Trimethylene Ethers of the Dihydroxybenzenes.** II. MORITZ KOHN and LEOPOLD SAFRIN (*Monatsh.*, 923, 49, 557—568; cf. preceding abstract).—*Phenyl o-hydroxyphenyl ethylene ether*,  $\text{OPh}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{OH}$ , is obtained on refluxing  $\beta$ -bromophenetole with a large excess of pyrocatechol and a little water, and adding the calculated amount of aqueous potassium hydroxide during half an hour; it forms crystals, m. p. 86.5°. Methylation by means of methyl sulphate yields the corresponding *phenyl o-anisyl ethylene ether*,  $\text{OPh}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{OMe}$ , long needles, m. p. 86—87°, which is identical with the product formed from guaiacol and  $\beta$ -bromophenetole in presence of sodium ethoxide. The *benzoyl* derivative,  $\text{OPh}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{OBz}$ , forms colourless prisms, m. p. 60—61°.

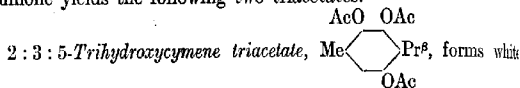

On treatment of the original phenyl *o*-hydroxyphenyl ethylene ether with a further molecule of  $\beta$ -bromophenetole in presence of sodium ethoxide, the substance *pyrocatechol bisphenoxyethyl ether* is formed,  $\text{C}_6\text{H}_4(\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{OPh})_2$ , forming platelets, m. p. 116—117°. The action of ethylene bromide on phenyl *o*-hydroxyphenyl ethylene ether in presence of sodium ethoxide yields the *bis- $\beta$ -phenoxy- $\gamma$ -ethoxyphenyl ethylene ether*,  $[\text{OPh}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{O}]_2\text{C}_2\text{H}_4$ , short, thin needles, m. p. 106—107°; if trimethylene bromide is used in place of ethylene bromide, the product is the *trimethylene bis- $\beta$ -phenoxy- $\gamma$ -ethoxyphenyl ether*,  $[\text{OPh}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{O}]_2\text{C}_3\text{H}_6$ , needles, m. p. 11°; the latter substance is also formed by the action of  $\beta$ -bromophenetole on dipyrocatechol trimethylene ether in presence of sodium ethoxide.

By refluxing phenyl  $\gamma$ -bromopropyl ether with a large excess of pyrocatechol in presence of a little water and the calculated quantity of potassium hydroxide, there is formed *phenyl o-hydroxyphenyl trimethylene ether*,  $\text{OPh}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{OH}$ , thick prisms, m. p. 56—57°; the *methoxy-ether* has m. p. 55—56°; the *benzoyl* derivative, needles, m. p. 60—61°. It reacts with a second molecule of phenyl  $\gamma$ -bromopropyl ether in presence of sodium ethoxide to form *pyrocatechol bisphenoxypropyl ether*,  $\text{C}_6\text{H}_4(\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{OPh})_2$ , needles, m. p. 51°; or using  $\beta$ -bromophenetole in place of phenyl  $\gamma$ -bromopropyl ether, the product is *pyrocatechol  $\beta$ -phenoxyethyl phenoxypropyl ether*,  $\text{OPh}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{C}_6\text{H}_4\cdot\text{O}\cdot\text{C}_3\text{H}_6\cdot\text{OPh}$ , prisms, m. p. 63—67.5°; the latter substance is also obtained by the converse

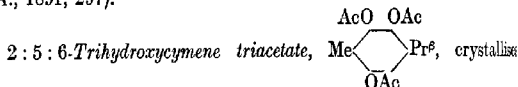

method from phenyl *o*-hydroxyphenyl ethylene ether and phenyl  $\gamma$ -bromopropyl ether. Two molecules of phenyl *o*-hydroxyphenyl trimethylene ether may be united by means of ethylene dibromide or trimethylene dibromide in presence of sodium ethoxide to yield, respectively, the substances *bis*- $\gamma$ -phenoxy-*o*-propoxyphenyl ethylene ether,  $C_6H_4(O-C_6H_4-O-C_3H_6-O-Ph)_2$ , needles, m. p. 102–103°, and *bis*- $\gamma$ -phenoxy-*o*-propoxyphenyl trimethylene ether,  $C_6H_4(O-C_6H_4-O-C_3H_6-O-Ph)_2$ , needles, m. p. 61–62°. The latter product is also formed from two molecules of phenyl  $\gamma$ -bromopropyl ether and one molecule of pyrocatechol trimethylene ether in presence of sodium ethoxide.

F. A. M.

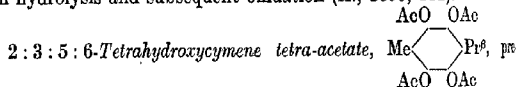

**Investigations on Phenols Derived from Cymene.** G. BARGELLINI (*Atti R. Accad. Lincei*, 1923, [v], 32, i, 231–235).—Thiele (A., 1898, i, 469) has shown that a new hydroxyl group may be introduced into the molecule of a quinol by treating the corresponding quinone with acetic anhydride in presence of a small amount of sulphuric acid. Application of this reaction to thymoquinone yields the following two triacetates.

crystals, m. p. 135–137°, and, on hydrolysis and subsequent oxidation, gives the 3-hydroxythymoquinone described by Mazzar (A., 1891, 297).

in white needles, m. p. 83–85°, and yields 6-hydroxythymoquinone on hydrolysis and subsequent oxidation (A., 1890, 884).

pared by the action of acetic anhydride in presence of a little sulphuric acid on either 3- or 6-hydroxythymoquinone or, better by oxidising either of these compounds to dihydroxythymoquinone m. p. 222–224°, and heating the latter with acetic anhydride and zinc dust, crystallises in white leaflets, m. p. 186–188°.

When dihydroxythymoquinone is reduced in alcoholic solution by means of hydrogen in presence of platinum black, the red solution absorbs hydrogen and is completely decolorised, but in contact with the air it rapidly reddens, the tetrahydroxycymene probably formed undergoing oxidation to the original dihydroxythymoquinone (cf. Henderson and Boyd, T., 1910, 97, 1663).

T. H. P.

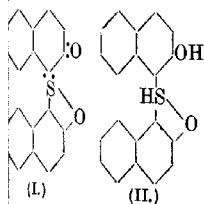

**Photo-sensitiveness of certain Urethanes.** A. KORCZYNSKI (*Gazzetta*, 1923, 53, i, 94–99).—Urethanes have been prepared by the action of diphenylcarbamide chloride on the following phenols: *p*-chloro-, bromo-, and iodo-phenols, *o*- and *p*-nitrophenols, 4-chloro-

and 4-bromo-2-nitrophenols, 4:6-dibromo- and 4:6-di-iodo-2-nitrophenols, 4-chloro-6-bromo-2-nitrophenol, 2:6-dichloro-4-nitrophenol, and 2:4:6-trichlorophenol. Photo-sensitiveness is shown by the compounds obtained from the halogenated nitrophenols with an ortho-nitro-group and a para-halogen atom, but not by those obtained from the halogenated or nitro-phenols; in the former case, introduction of a second halogen atom in the second ortho-position leaves the photo-sensitiveness unchanged. The photochemical change occurring in these compounds is more destructive than the similar phenomenon observed, for instance, with *o*-nitrobenzaldehyde (Ciamician and Silber, A., 1901, i, 390, 547; 1902, i, 434), since the nitroso-compound cannot be isolated; no marked change occurs, however, in the diphenylaminic portion of the molecule. The fact that the condensation of 2:4-dinitrophenol or of picric acid with diphenylcarbamide chloride yields, not the corresponding carbamic ester, but a non-homogeneous, resinous mass, is explainable by the occurrence of a photochemical reaction.

[With Sr. GRZYBOWSKI.]—4-Chlorophenyl N-diphenylcarbamate,  $C_6H_4ClO-CO-NPh_2$ , forms colourless needles, m. p.  $97^\circ$ ; the 4-bromophenyl ester, colourless needles, m. p.  $99^\circ$ ; the 4-iodophenyl ester, m. p.  $126-127^\circ$ ; the 2:4:6-trichlorophenyl ester, colourless needles, m. p.  $143^\circ$ ; the 2-nitrophenyl ester, colourless crystals, m. p.  $108-109^\circ$ ; the 4-nitrophenyl ester, colourless needles, m. p.  $112^\circ$ ; the 2:6-dichloro-4-nitrophenyl ester, colourless needles, m. p.  $132^\circ$ ; the 4-chloro-2-nitrophenyl ester, m. p.  $124-125^\circ$ , is photo-sensitive; the 4-chloro-6-bromo-2-nitrophenyl ester, m. p.  $140^\circ$ , is photo-sensitive; the 4:6-dibromo-2-nitrophenyl ester, m. p.  $139^\circ$ , is photo-sensitive; the 4:6-di-iodo-2-nitrophenyl ester, m. p.  $174-175^\circ$ ; the 4-bromo-2-nitrophenyl ester forms lustrous, colourless needles, m. p.  $129-130^\circ$ , and is photo-sensitive, both in the crystalline condition and in solution in neutral solvents such as benzene, toluene, ethyl or amyl alcohol, and also in absence of oxygen. T. H. P.

#### The Isomerism of $\beta$ -Naphthol Sulphide and the Analogous Isomerism of Aromatic *o*-Hydroxysulphides.

RUDOLF LESSER and GEORG GAD (*Ber.*, 1923, 56, [B], 963-978).—The isomerism of  $\beta$ -naphthol sulphides has been examined in detail by Smiles and his co-workers (T., 1911, 99, 973; 1912, 101, 710; 1146, 1420; 1913, 103, 340, 901; 1914, 105, 1396, 1739, 1744), and by Hinsberg (A., 1915, i, 237, 808; 1916, i, 723). The former has drawn the conclusion that it is due to the mode of union within

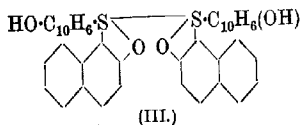

the naphthalene nuclei, the latter that it is caused by the structure of the sulphur atom itself. It is now shown, however, that the isomerism is not of an abnormal type, since if the constitution (I) assigned by Hinsberg to the dehydrosulphide is adopted it is readily possible that this may pass on reduction into the compound II without rupture of the "thionylum" (the term is applied by the authors to the structure,

$-\text{CH} \begin{smallmatrix} > \text{S} < \\ \text{CH} & \text{O} \end{smallmatrix}$ ). This constitution is in complete harmony with the behaviour of the isosulphide. The ability to form dehydro-compounds, and hence also isosulphides, is not restricted to naphthalene derivatives, but is common to aromatic *o*-hydroxy-sulphides which have a substituent in the para-position to the hydroxy-group and a tertiary carbon atom in the ortho-position to the sulphur atom.

During the course of the work it has been frequently necessary to chlorinate phenols in order to introduce a substituent into the para-position. This has been effected by sulphuryl chloride, but it has been observed that reaction does not occur, at any rate under the usual conditions, if the phenol contains a negative substituent in the ortho-position to the hydroxy-group as in *o*-chlorophenol, *o*-nitrophenol, salol, *o*-hydroxydiphenyl, *o*-chloro-*s-m*-xylene. The general assumption that sulphuryl chloride only chlorinates phenols in the para-position is shown to be incorrect, since ortho-derivatives are simultaneously produced in varying amounts. The chlorides of sulphur do not react with phenols which contain a negative substituent in the ortho-position to the hydroxy-group and a substituent in the para-position such as dichloro-*s-m*-xylene, *p*-chloro-*o*-nitrophenol, *o*-chloro-*p*-nitrophenol and *o*-nitro-*p*-cresol.

With regard to the nomenclature of the group, the authors propose to retain the terms "dehydrosulphide" and "isosulphide," and to distinguish between the dehydro-compounds which contain a single and double thionylum ring by appending in brackets the expressions "quinoid form" (as in formula I) and "spiran form" (as in formula IV).

$\beta$ -Naphthol sulphide, its dihydro-compound, and the isosulphide are prepared in the usual manner. The latter is oxidised by iodine

to diiso- $\beta$ -naphthol sulphide (annexed formula III), m. p. 141–142°, which is identical with the compound obtained by Hinsberg by the action of hydrogen peroxide on the isosulphide. It is converted by benzoyl chloride and sodium hydroxide into the corresponding dibenzoate, yellow platelets (+C<sub>6</sub>H<sub>5</sub>), m. p. 202–203°, which is reduced by zinc dust and hydrochloric acid to *o-monobenzoyliso- $\beta$ -naphthol sulphide*, pale yellow prisms, m. p. 111–112°, which is reconverted by iodine into the parent dibenzoate. The isomeric *S-monobenzoyliso- $\beta$ -naphthol sulphide*, pale yellow platelets m. p. 181°, is prepared from the isosulphide and benzoyl chloride in the presence of pyridine, and is converted into *dibenzoyliso- $\beta$ -naphthol sulphide*, colourless platelets, m. p. 179–180°, which is also obtained from the *O*-benzoyl compound or from the isosulphide itself. *Monobenzoyl- $\beta$ -naphthol sulphide* crystallises in colourless lustrous platelets, m. p. 190°, whereas the corresponding *p-benzoyl* derivative forms small, colourless needles, m. p. 195°.

**6-Bromo-2-naphthol sulphide**, long, colourless needles, m. p. 245—46°, is prepared by the action of sulphur chloride on 6-bromo-naphthol suspended in carbon disulphide. The corresponding *dibenzoyl* compound crystallises in colourless, felted needles, m. p. 70°. The sulphide is oxidised by potassium ferricyanide in alkaline solution to *dehydro-6-bromo-2-naphthol sulphide* (*quinoid form*), ruby-red, cubic crystals, m. p. 176—177° [*mono-p-nitro-phenylhydrazone*, orange-yellow needles, m. p. 254° (decomp.)], which is reduced by zinc dust in the presence of benzene and hydrochloric acid to *iso-6-bromo-2-naphthol sulphide*, pale yellow platelets, m. p. 156—157° (*dibenzoyl* derivative, small, colourless needles, m. p. 184—185°).

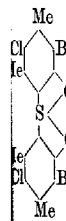

**Methyl 2-hydroxynaphthalene-3-carboxylate 1-sulphide** forms lemon-yellow crystals, m. p. 227—228° (*dibenzoate*, colourless platelets, m. p. 231—232°); it is oxidised by bromine to the *dehydro*-compound (*spiran form*) (annexed formula IV), dark red crystals, m. p. 245—246°, which is reduced by zinc dust and hydrochloric acid in the presence of benzene to *methyl iso-2-hydroxynaphthalene-3-carboxylate-1-sulphide*, yellow crystals, m. p. 227—228°, which appears to pass below its melting point into the normal sulphide; the corresponding *dibenzoyl* derivative forms yellow crystals, m. p. 176°.

(IV.)

*s-m*-Xylenol, dissolved in chloroform, is converted by the theoretically necessary amount of sulphuryl chloride into a mixture of 2-chloro-*s-m*-xylenol, long, colourless prisms, m. p. 115—116°, and minor quantities of 6-chloro-*s-m*-xylenol, colourless needles, m. p. 49—50°; an excess of the reagent produces *dichloro-s-m*-xylenol, m. p. 95—96°. The *p*-chloro-derivative is converted by sulphur chloride in the presence of chloroform into 2-chloro-*s-m*-xylenol 4-sulphide, small, colourless needles, m. p. 214—215°, which

is transformed successively by bromine in the presence of alkali hydroxide into 2-chloro-6-bromoxylene 4-sulphide, colourless, lustrous needles, m. p. 215—216°, and *dehydro-2-chloro-6-bromo-s-m-xylene sulphide* (*spiran form*) (annexed formula), coarse, dark red crystals, m. p. 195° (the mother-liquors from the crystals contain 2-chloro-4:6-dibromo-*s-m*-xylenol, long, asbestos-like needles, m. p. 158°). The *dehydro*-compound is converted by zinc dust and hydrochloric acid in the presence of benzene into *iso-2-chloro-6-bromo-s-m-xylene 4-sulphide*, pale yellow prisms, m. p. 177°, which is oxidised smoothly by iodine in the presence of sodium hydrogen carbonate solution to *diiso-2-chloro-6-bromo-s-m-xylene sulphide*, pale yellow, cubic crystals, m. p. 127° (decomp.).

*p*-Xylenol is converted by sulphuryl chloride in the presence of chloroform into *chloro-p-xylene*, needles, m. p. 74—75°, after previous softening, which is transformed by sulphur chloride into *chloro-p-xylene sulphide*, colourless needles, m. p. 180—181°. *Chlorothymol sulphide*, [S : OH : C<sub>3</sub>H<sub>7</sub> : Cl : Me = 2 : 3 : 4 : 6 : 1], forms

large, glassy crystals, m. p. 110—111°. *φ-Cumenol sulphide* crystallises in colourless, lustrous needles, m. p. 127—128°. The sulphides described in this paragraph are oxidisable to coloured dehydro-compounds.

The following phenolic sulphides do not contain a substituent in the ortho-position to the sulphur atom and do not yield dehydro-compounds: *m-Xylenol sulphide*, almost colourless prisms, m. p. 96—98°; *6-chloro-m-cresol sulphide*, colourless, lustrous needles, m. p. 180—181°.

H. W.

**Aldol Condensation between Chloral and Phenols.** H. PAULY and HEINRICH SCHANZ (*Ber.*, 1923, 56, [B], 979—985).—Aldol condensations between aldehydes and phenols have only been observed previously between exceptionally reactive members of these classes of compounds. The type of change, however, appears to be general, since chloral is found to react in this manner with a number of phenols. The phenolic hydroxy-group remains intact in the new compounds.

Chloral hydrate and phenol are melted together, and so much powdered potassium carbonate is added to the mixture that litmus paper is just turned blue, after which it is preserved for six weeks at the atmospheric temperature, during which time *4-hydroxy-phenyltrichloromethylcarbinol*,  $\text{HO}\cdot\text{C}_6\text{H}_4\cdot\text{CH}(\text{OH})\cdot\text{CCl}_3$ , needles, m. p. 87°, slowly separates. The corresponding *monoacetate*,

crystallises in needles, m. p. 173°. The constitution of the condensation product is deduced from the observation that it is converted by phenol in the presence of glacial acetic and concentrated sulphuric acids into the previously described  $\beta\beta$ -trichloro- $\alpha\alpha$ -bis-*p*-hydroxyphenylethane, m. p. 202°. Under similar conditions, *p*-cresol gives *p-tolyltrichloromethylcarbinol*, colourless needles, m. p. 147—148°, and guaiacol yields *4-hydroxy-3-methoxyphenyltrichloromethylcarbinol*, colourless needles, m. p. 118—119° (*monoacetate*, slender needles, m. p. 124°). The constitution assigned to the latter substance is deduced from its conversion into vanillin. *Trichlorodiguaiacylthane* is prepared from the guaiacolcarbinol and guaiacol or from chloral and guaiacol in the presence of glacial acetic and concentrated sulphuric acids; it is non-crystalline and does not exhibit a definite melting point. It separates from carbon tetrachloride in colourless needles ( $+\text{CCl}_4$ ), m. p. 98°, and from chloroform ( $+\text{CHCl}_3$ ) in slender needles. It is converted by reduction with zinc dust into *4:4'-dihydroxy-3:3'-dimethoxystilbene* (?), slender needles, m. p. 200°. Pyrocatechol and chloral yield *2:3-(or 3:4)-dihydroxyphenyltrichloromethylcarbinol*, small, colourless needles, m. p. 128—129°, whereas resorcinol and chloral hydrate give *2:4-dihydroxyphenyltrichloromethylcarbinol*, colourless needles, m. p. 176°.

H. W.

**The Action of Magnesium on a Mixture of Bromoallene with Cuminol.** K. VOLKOV (*J. Russ. Phys. Chem. Soc.*, 1917, 49, 259—263).—*Cumylallylcarbinol*,  $\text{C}_6\text{H}_4\text{Pr}^s\cdot\text{CH}(\text{C}_3\text{H}_5)\cdot\text{OH}$ , b. p.

140°/17.5 mm.,  $d_4^{25}$  0.9470,  $n_D^{25}$  1.51385, is prepared by the addition of magnesium to a mixture of cuminaldehyde,  $C_6H_5Pr^o\text{-CHO}$ , and  $\alpha$ -bromoallene. The carbinol on oxidation with potassium permanganate yields a mixture of  $\beta$ -hydroxy- $\beta$ -cumylpropionic and  $p$ -isopropylcinnamic acids.

R. T.

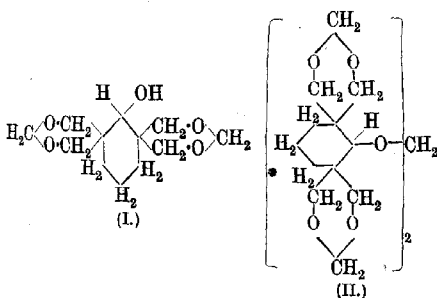

**Synthesis of Keto-alcohols and Polyhydroxy-alcohols from Cyclic Ketones and Formaldehyde.** C. MANNICH and W. BROSE (*Ber.*, 1923, 56, [B], 833—844).—Tollens's method for the production of polyhydroxy-alcohols by the action of an excess of formaldehyde on aliphatic aldehydes and ketones in the presence of milk of lime has been extended to cyclic ketones, including cyclohexanone, *o*- and *p*-methylcyclohexanones, cyclopentanone, menthone, carvone, and camphor. With the three substances last mentioned, a condensation could not be effected. In the case of cyclohexanone and its *o*- and *p*-methyl derivatives, the action follows the expected course, two hydroxymethyl groups being introduced at each carbon atom vicinal to the ketonic group and the latter suffering reduction to the secondary alcoholic group when excess of formaldehyde is employed. When smaller quantities of the latter are taken it is possible to control the action in such a manner that keto-alcohols are produced. With cyclopentanone, on the other hand, the reaction follows a rather different course, yielding either condensation products of high molecular weight or a tetrahydroxy-keto-alcohol according to the proportion of formaldehyde employed.

2 : 2 : 6 : 6-Tetrahydroxymethylcyclohexane-1-ol,

colourless, quadratic plates, m. p. 131° (corr.), is prepared by allowing a homogeneous mixture of cyclohexanone, formaldehyde, and water to remain in contact with slaked lime at 30° during several days. It gives a *penta-acetate*, needles, m. p. 75° (corr.). It is converted by formaldehyde (30%) and concentrated hydro-

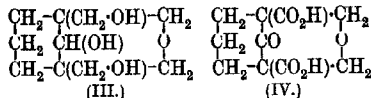

chloric acid into a mixture of the *bismethylene ether* (annexed formula I), colourless plates, m. p. 119° (corr.) [corresponding *monoacetate*, pointed rhombs, m. p. 135° (corr.)],

and the compound (annexed formula II), colourless, lustrous leaflets,

x\*

m. p. 242° (corr.). Hydrogen chloride at 150—160° converts 2:2:6:6-tetrahydroxy-methylcyclohexane-1-ol into the cyclic ether (annexed formula III), colourless crystals, m. p. 144° (corr.) [correspond-

ing triacetate, colourless plates, m. p. 72° (corr.)], which is oxidised by concentrated nitric acid to the dicarboxylic *keto-acid* (annexed formula IV), colourless needles, m. p. 218° (corr.). The latter substance is converted by phenylhydrazine into the compound,  $\text{C}_{16}\text{H}_{16}\text{O}_4\text{N}_2$ , small, colourless needles, m. p. 251° (corr.).

*cyclohexanone* is converted by four molecular proportions of formaldehyde into 2:2:6:6-tetrahydroxymethylcyclohexane-1-one, colourless, four-sided, double pyramids, m. p. 143° (corr.) [corresponding *tetra-acetate*, colourless prisms, m. p. 140° (corr.)]. The presence of the ketonic group cannot be established directly, since the compound could not be caused to react with phenylhydrazine, semicarbazide, or hydroxylamine, and the possibility of a cyclic structure is therefore not excluded. Indirectly, however, this can be effected, since the corresponding *bismethylene ether*, colourless prisms, m. p. 150° (corr.), is reduced by alcohol and a large excess of sodium to the bismethylene ether of tetrahydroxymethylcyclohexanol which is identical with the product (formula I) described above. The *bisbenzylidene ether* of 2:2:6:6-tetrahydroxymethylcyclohexane-1-one, long, colourless needles, m. p. 230·5° (corr.), is readily prepared from the parent substance, benzaldehyde, and hydrochloric acid and is resolved into its components by treatment with boiling mineral acid.

2-Hydroxymethylcyclohexane-1-one is prepared from equimolecular proportions of *cyclohexanone* and formaldehyde. It is a colourless liquid, b. p. 114—115°/16 mm., which is sensitive towards both acids and alkalis. It gives a *monoacetate*, a colourless liquid, b. p. 134—136°/15 mm. (prepared by the aid of acetyl chloride in the presence of pyridine), and a *phenylhydrazone*, small, colourless prisms, m. p. 129°.

*p*-Methylcyclohexanone and formaldehyde (5·5 molecular proportions) give 4-methyl-2:2:6:6-tetrahydroxymethylcyclohexane-1-ol, small, colourless needles, m. p. 150° (corr.), which is further characterised by its conversion by acetic anhydride and sodium acetate into the *penta-acetate*, leaflets, m. p. 139° (corr.).

The product obtained by the similar condensation of *o*-methylcyclohexanone with formaldehyde could not be caused to crystallise, and was therefore treated with benzaldehyde and concentrated hydrochloric acid, whereby the *bisbenzylidene ether* of 2-methyl-2:6:6-trihydroxymethylcyclohexane-1-ol was obtained in colourless prisms, m. p. 133° (corr.). Treatment of the ether with hot aqueous hydrochloric acid leads to the production of 2-methyl-2:6:6-trihydroxymethylcyclohexane-1-ol, short, colourless prisms, m. p. 100° (corr.).

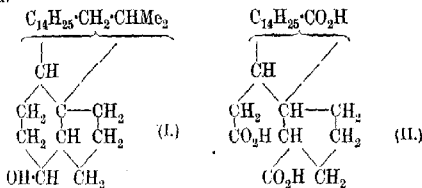

Treatment of *cyclopentanone* with a large excess of formaldehyde

and slaked lime causes the slow formation of insoluble, amorphous condensation products. With 4-6 molecular proportions of aldehyde and moderate quantities of slaked lime, 2:2:5:5-tetrahydroxymethylcyclopentane-1-one, colourless plates, m. p. 143° (corr.), is produced. The presence of four hydroxy-groups is established by the isolation of a tetrabenzoate, colourless needles, m. p. 144° (corr.). The compound, however, does not appear to react with phenylhydrazine, semicarbazide, hydroxylamine, or hydrogen cyanide; attempts to reduce it to the corresponding secondary alcohol were unsuccessful. It yields a bismethylene ether, m. p. 182° (corr.), and a bisbenzylidene ether, long, colourless needles, m. p. 206.5° (corr.). The bismethylene ether is reduced by sodium and boiling alcohol to the bismethylene ether of 2:2:5:5-tetrahydroxymethylcyclopentane-1-ol, colourless plates, m. p. 81° (corr.), which gives a monoacetate, prisms, m. p. 106° (corr.).

H. W.

#### Conversion of Coprosterol into isoLithobilianic Acid. A.

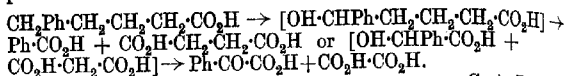

INDAUS and TH. RIEMANN (*Z. physiol. Chem.*, 1923, 126, 277-30).—Coprosterol, (I), when oxidised yields an acid,  $C_{27}H_{46}O_4$ ; it is now shown that this acid on further oxidation yields isoLithobilianic acid, (II), m. p. 262° (dimethyl ester, m. p. 204°), and the constitution assigned to these substances has thus been confirmed.

W. O. K.

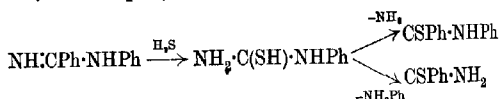

The Oxidising Action of Alkaline Potassium Permanganate on Normal Phenyl-fatty Acids. EUGENI STEPANOVITSCH PESHEVALSKI (*J. Russ. Phys. Chem. Soc.*, 1917-1918, 49, 57-572).—The oxidation of phenylated fatty acids in the animal organism has been shown by Dakin (A., 1908, ii, 964; 1910, ii, 795) and by Knoop (A., 1905, ii, 46) to take place at the  $\beta$ -carbon atom. It is now shown that hot alkaline permanganate in all cases attacks the carbon atom next to the phenyl group, a hydroxyl group being introduced; this may then be further oxidised to a keto- and finally to a carboxyl-group, forming benzoic acid; the remainder of the side-chain is oxidised to carbon dioxide or a dibasic acid. On the other hand, after the entrance of the first hydroxyl group into the molecule, the next carbon atom may be attacked and oxidised to carboxyl, forming a hydroxy- or keto-acid (mandelic or phenylglyoxylic acid), the remainder of the side-chain being oxidised to carbon dioxide or a dibasic acid. Thus, phenylacetic

acid yields benzoic and phenylglyoxylic acids; phenylpropionic acid gives mainly mandelic acid, also some benzoic and oxalic acid; the latter are the main products from phenylbutyric acid, in addition to some phenylglyoxylic acid; phenylvaleric acid gives the same three products in addition to succinic acid. The oxidation of phenylvaleric acid is thus an illustration of both the suggested processes:

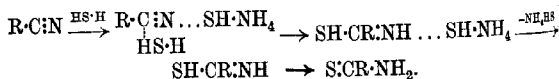

G. A. R. K.

**The Mechanism of Chemical Reactions. I. Reduction of Amides and Oxidation of Amines.** KARL KINDLER [and, in part, F. BURGHARD, F. FINNDORF, W. DEHN, O. GIESE, and P. KÖRDING] (*Annalen*, 1923, 431, 187—230).—It is already known that the addition of hydrogen sulphide to a nitrile group which is not attached to a negative residue (Ph or CN) cannot be effected unless ammonium hydrogen sulphide is present (Bernthsen, A., 1877, i, 616). This is not due to the intermediate production of an amidine:  $\text{R}\cdot\text{C}\cdot\text{N} \xrightarrow{+\text{NH}_3} \text{NH}\cdot\text{CR}\cdot\text{NH}_2 \xrightarrow{\text{H}_2\text{S}} \text{NH}_3 + \text{S}\cdot\text{CR}\cdot\text{NH}_2$ , because the action of alcoholic hydrogen sulphide, saturated at  $-10^\circ$ , on benzonitrile and dimethylamine at  $80-90^\circ$  leads only to the formation of thiobenzamide in 100% yield; if the reaction proceeded according to the above scheme, an *N*-alkylthioamide would also be produced, since hydrogen sulphide acts on phenylbenzylamine, for example (Bernthsen, A., 1878, 788), as follows:

The promotion of this reaction by means of ammonium hydrogen sulphide is therefore considered to be due to the intermediate formation of molecular compounds:

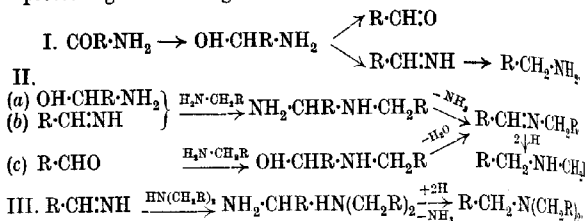

This view is confirmed by the fact that alkali hydrogen sulphides are even more efficient catalysts than ammonium hydrogen sulphide. Thus benzyl cyanide, heated for one and a half days at  $70^\circ$  with alcoholic hydrogen sulphide saturated at  $-10^\circ$ , does not give phenylthioacetamide, but if ammonia, dimethylamine, sodium hydroxide, or potassium hydroxide is added, the yield of this amide is 77, 81, 89, and 91%, respectively. The conversion is seldom quantitative, because the reaction is reversible; the same equilibrium:  $\text{RCN} + \text{H}_2\text{S} \rightleftharpoons \text{R}\cdot\text{CS}\cdot\text{NH}_2$  (89% theory) is attained in the presence of alcoholic sodium hydrogen sulphide, starting

from phenylthioacetamide. In the presence of alkali hydrogen sulphide or dimethylammonium hydrogen sulphide in dry benzene solution, the following thioamides are prepared from the relevant nitriles in the yields stated. Thioacetamide, 66%; thiopropionamide, 43%; thio-*p*-toluamide, 78%; thio- $\beta$ -naphthoamide, 88%; phenylthioacetamide, 83%; thioamide of acetylmandelic acid,  $\text{CO}_2\text{Me}\cdot\text{CHPh}\cdot\text{CS}\cdot\text{NH}_2$ , 70%; phenylthiopropionamide, m. p. 87°, 84%. Aliphatic and aliphatic-aromatic selenoamides are produced in the same way. Phenylacetoneitrile reacts at 80° with alcoholic hydrogen selenide, saturated at -10°, containing sodium hydrogen selenide, giving an almost quantitative yield of phenylselenoacetamide, glistening, white crystals, m. p. 92—92.5°; selenoacetamide, m. p. 126—126.5°, is obtained in the same way, yield 17%, from acetoneitrile.

The action of phosphorus pentasulphide on amides (Hofmann, A., 1878, 396) occurs in two stages. If the reaction is conducted in cold carbon disulphide solution, using *N*-dimethylbenzamide, the only additive product,  $\text{NH}_2\cdot\text{CR}\cdot\text{O}\dots(\text{S}_2)\text{P}\cdot\text{S}\cdot\text{P}(\text{S}_2)\dots\text{O}\cdot\text{C}(\text{NH}_2)\text{R}$  (cf. Pfeiffer, *Organischer Molekülverbindungen*, 1922, 156), may be isolated. This is decomposed by means of water into the amide, phosphoric acid, and hydrogen sulphide, but gives thiobenzodimethylamide, m. p. 67° (corr.), b. p. 180—182°/18 mm., in 93% yield, on being repeatedly extracted by means of warm xylene. The formation of the thioamide is considered to take place by an interchange of oxygen and sulphur atoms in the additive compound, followed by dissociation. The following thioamides are formed with especial readiness in the presence of potassium sulphide. Thioacetamide, 75%; phenylthioacetamide, 48%; phenylthiopropionamide, 45%; *N*-methylthiobenzamide, 78%; phenylthioacetothylamide, colourless plates, m. p. 62.5—63° (corr.), 75%; phenylthioacetodimethylamide, colourless crystals, m. p. 80—81° (corr.), 80%;  $\beta$ -phenylthiopropionodimethylamide, red oil, 83%.

The reduction of phenylacetamide by means of sodium and methyl alcohol leads to the formation, not only of  $\beta$ -phenylethylamine, but also of di-( $\beta$ -phenylethyl)amine. Moreover, secondary and even tertiary amines are produced when thioamides are reduced by means of aluminium amalgam in moist ethereal or alcoholic solution. Thus in ethereal solution the following amines are formed from the corresponding thioamides. 88% Benzylamine, 7% dibenzylamine, and traces of tribenzylamine. 84% *p*-Methylbenzylamine, 15% di-(*p*-methylbenzyl)amine. 26%  $\beta$ -Phenylethylamine, 66% di-( $\beta$ -phenylethyl)amine. 35%  $\gamma$ -Phenylpropylamine, 15% di-( $\gamma$ -phenylpropyl)amine,  $(\text{CH}_2\text{Ph}\cdot\text{CH}_2\cdot\text{CH}_2)_2\text{NH}$ , b. p. 245°/35 mm., hydrochloride, m. p. 203° (corr.) (cf. Rupe and Glenz, this vol., i, 100). In alcoholic solution, 69% benzylamine, 21% dibenzylamine, and traces of tribenzylamine; 74% *p*-methylbenzylamine, 15% secondary amine; 22%  $\beta$ -phenylethylamine, and 21% secondary amine are produced. To explain these results, the intermediate formation of an aminoalcohol,  $\text{OH}\cdot\text{CHR}\cdot\text{NH}_2$ , or aminothioalcohol,  $\text{SH}\cdot\text{CHR}\cdot\text{NH}_2$ , is postulated, the production of primary, secondary, or tertiary amine from an amide being then

expressed by the following scheme, the reduction of a thioamide proceeding in an analogous manner :

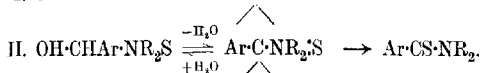

In accordance with this explanation, secondary and tertiary amines are not formed in acid solution; the aminothio-alcohol, being unstable to acids, undergoes fission to an aldehyde or to an aldimine, the latter being further reduced to a primary amine. Thus the electrolytic reduction of phenylthioacetamide in alcoholic hydrogen chloride solution leads to a 63% yield of  $\beta$ -phenylethylamine, and the reduction of thiobenzamide in dilute acetic acid solution by means of iron powder in an atmosphere of carbon dioxide gives benzaldehyde in a yield corresponding quantitatively with the amount of unrecovered thioamide. Moreover, the reduction of phenylthioacetamide by means of aluminium amalgam in moist ethereal solution containing ethylamine gives  $\beta$ -phenylethylamine, di-( $\beta$ -phenylethyl)amine, and  $\beta$ -phenylethylethylamine, *hydrochloride*, whilst  $\beta$ -phenylethyldimethylamine is formed in the presence of dimethylamine. *N*-Monoalkyl or dialkyl amides or thioamides also pass first into the aminoalcohol or aminothioalcohol. Hence the electrolytic reduction of thiobenzanilide in 80% sulphuric acid solution at 15–20°, using a current density 0.15 amp./sq. cm., gives about 10% benzalaniline besides considerable amounts of aniline and benzaldehyde, whilst under similar conditions *N*-benzothiodimethylamide gives benzyldimethylamine, dimethylamine, and about 40% benzaldehyde. The preparation of tertiary amines from thiodialkylamides may, however, be accomplished by reduction in 60% sulphuric acid solution, using a current density 0.3 amp./sq. cm. Thiobenzodimethylamide, phenylthioacetodimethylamide, and  $\beta$ -phenylthiopropionodimethylamide give, respectively, benzyldimethylamine, 100%,  $\beta$ -phenylethyldimethylamine, 100%, and  $\gamma$ -phenylpropyldimethylamine, 73%. Benzylmethylamine, *p*-methoxybenzylmethylamine, and  $\beta$ -phenylethylmethylamine are obtained in yields of 79, 84, and 83%, respectively, by the reduction of the corresponding thioamides in concentrated hydrochloric acid solution. The reduction by means of aluminium amalgam of thioacetanilide, in ethereal solution, of thiobenzomethylamide, and of thiobenzodimethylamide, in alcoholic solution, gives ethylamine, 100%, benzylmethylamine, 70%, and benzyldimethylamine, 60%, respectively.

Benzylamine is oxidised to benzamide by means of cold alkaline potassium permanganate (cf. Bamberger and Scheutz, A., 1901

i, 587), but at 100° only benzoic acid and ammonia are produced; hence benzaldoxime is not an intermediate product. The parallel conversion of amines into thioamides by heating with sulphur (Wallach, A., 1891, 189) proceeds more readily, but has only been accomplished in the arylmethylamine series. Hence the reaction might be supposed to proceed through an aldimine:

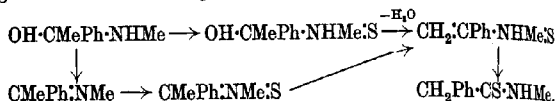

but for the fact that tertiary amines, which cannot be converted into aldimines, undergo this reaction. Thus benzyldimethylamine gives thiobenzodimethylamide when heated for four hours at 180° with sulphur (2 atoms). That in the oxidation of amines an amino-alcohol is primarily formed is supported by the fact (Pickard and Carter, T., 1901, 79, 520) that amino-alcohols can be oxidised to amides; moreover, both amino-alcohols and aminothio-alcohols may be converted into thioamides by heating with sulphur (see below). This is not merely dehydrogenation:  $\text{OH}\cdot\text{CHR}\cdot\text{NR}_2 + \text{S} = \text{R}\cdot\text{CO}\cdot\text{NR}_2 + \text{H}_2\text{S}$ , since the corresponding amides do not react with sulphur under similar conditions. Indeed, whether the amino-alcohol or the aldimine is the intermediate product, the formation of a compound of bivalent carbon must be postulated:

The aldehyde or ketone and ammonia or the amine are mixed in equivalent proportions, with cooling, and the mixture is heated with sulphur for three hours at 170–180°. Benzaldehyde and ammonia give thiobenzamide. *p*-Tolualdehyde and methylamine give *thio-p-tolumethylamide*, m. p. 55°. Benzaldehyde and  $\beta$ -naphthylamine give *thiobenzo- $\beta$ -naphthylamide*, m. p. 106–107°. Benzaldehyde and dimethylamine give thiobenzodimethylamide; benzaldehyde and diethylamine give *thiobenzodiethylamide*, b. p. 194°/18 mm. Anisaldehyde and dimethylamine give *thio-p-methoxybenzodimethylamide*, m. p. 68.5°. Phenylacetaldehyde and dimethylamine give phenylthioacetodimethylamide. Similar compounds are produced by the action of sulphur on aldimines and ketimines; these are prepared by heating an equimolecular mixture of a primary amine and an aldehyde or ketone at 80–90° for three to four hours, and distilling the product under reduced pressure. Benzyldimethylamine gives *N*-methylthiobenzamide. *p*-Methoxybenzylidenemethylamine,  $\text{OMe}\cdot\text{C}_6\text{H}_4\cdot\text{CH}\cdot\text{NMe}$ , b. p. 129–130°/18 mm., gives *p*-methoxythiobenzomethylamide, m. p. 108–109°. Benzyldiene-aniline gives thiobenzanilide and  $\alpha$ -phenylethylidenemethylamine,  $\text{CMePh}\cdot\text{NMe}$ , b. p. 96°/10 mm., gives phenylthioacetomethylamide. Phenylthioacetodimethylamide is produced when acetophenone and dimethylamine are heated with sulphur. Similarly, *p*-acetylanisole and dimethylamine give *p*-methoxyphenylthioacetodimethyl-

amide, m. p. 75—76°, whilst the products when diethylamine is used are, respectively, *phenylthioacetodiethylamide*, b. p. 184°/12 mm., and *p-anisylthioacetodiethylamide*, b. p. 220°/12 mm. In these reactions, the migration of an alkyl group must occur. It is suggested that the intermediate hydramine or ketimine forms an amine sulphide; this is followed by dehydration or migration of a hydrogen atom, giving an ethylene derivative, which then undergoes molecular rearrangement to the thioamide:

It is indicated that amino-alcohols may be intermediate products in the interconversion of amines and amides in plants and animals.

Use is made of thioamides in the synthesis of hordenine and hydrastinine. *p*-Nitrophenylacetodimethylamide, when treated with phosphorus pentasulphide and potassium sulphide, gives *p*-nitrophenylthioacetodimethylamide, yellowish-green prisms or leaflets, m. p. 131° (corr.), yield 90%, which on electrolytic reduction in 60% sulphuric acid solution gives *p*-amino- $\beta$ -phenylethylmethylamine,  $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{CH}_2\cdot\text{CH}_2\cdot\text{NMe}_2$ , colourless crystals, m. p. 40—42° (corr.), b. p. 137—138°/6 mm., *hydrochloride*, m. p. 261° (corr.). By diazotisation and warming in aqueous solution, hordenine is obtained in 95% yield. When the *N*-methylammonium salt of homopiperonylic acid is heated at 185—195° for two hours in an atmosphere of methylamine, an 85% yield of homopiperonylmethylamide, m. p. 106° (corr.), is obtained. This is treated with phosphorus pentasulphide and potassium sulphide, giving homopiperonylthiomethylamide, m. p. 136° (corr.), yield 82%, which is converted by electrolytic reduction in alcoholic hydrochloric acid solution into piperonylmethylamine, yield 80%, from which hydrastinine is obtained by the method of Decker and Becker (A., 1913, i, 290).

**The Resolution of *p*- and *m*-Nitrophenoxypropionic Acids.**  
E. FOURNEAU and G. SANDULESCO (*Bull. Soc. chim.*, 1923, [iv], 33, 459—465).—The resolution of *o*-nitrophenoxypropionic acid by means of cinchonine, strychnine, and yohimbine has already been described (*loc. cit.*, 1922, 31, 988), but the methods which were successful with the ortho-acid do not give uniformly good results with the meta- and para-acids. The cinchonine and cinchonidine salts of the para-acid are oily or gummy and fail to crystallise, whilst the crystallisation of the strychnine and brucine salts is good, but no resolution occurs. On the other hand, *L*-*p*-nitrophenoxypropionic acid was obtained in good yield by the fractional crystallisation of the yohimbine salt. It melts at 89—90° and has  $[\alpha]_D -53.7^\circ$ . The *d*-acid was obtained by means of the quinidine salt. For the resolution of the meta-acid strychnine gave the best results amongst the various alkaloids tried. The salt of the *l*-acid crystallised out, and had a constant rotation after three

recrystallisations,  $[\alpha]_D -25^\circ$ . The free *l*-nitrophenoxypionic acid had m. p.  $101-102^\circ$ , and  $[\alpha]_D -51.87^\circ$ . G. F. M.

**Researches on Residual Affinity and Co-ordination. XVI. Normal and Acid Salicylatotetramminocobaltic Salts.** GILBERT T. MORGAN and J. D. MAIN SMITH (T., 1923, 123, 1096-1108).

**Silver Derivative of Amino-thiolbenzoic Acid.** A. FELDT (U.S. Pat. 1439624).—Interaction of a silver salt, in particular silver nitrate, with 4-amino-2-thiolbenzoic acid yields the compound,  $\text{AgS}\cdot\text{C}_6\text{H}_4(\text{NH}_2)\cdot\text{CO}_2\text{H}$ , a colourless powder, m. p.  $205^\circ$ .

## CHEMICAL ABSTRACTS.

**Oxalic Acid Derivatives of Benzo- and *p*-Tolu-acetodinitriles.** ERICH BENARY, HELENE SOENDEROP, and ERICH BENNEWITZ (Ber., 1923, 56, [B], 910-917).—A continuation of previous work (cf. Benary and Schmidt, A., 1921, i, 776).

*Ethyl  $\gamma$ -imino- $\beta$ -cyano- $\alpha$ -keto- $\gamma$ -phenylbutyrate*,  $\text{NH}\cdot\text{CPh}\cdot\text{CH}(\text{CN})\cdot\text{CO}\cdot\text{CO}_2\text{Et}$ , lustrous plates, decomp.  $165-167^\circ$ , is prepared by the action of benzoacetodinitrile, ethoxalyl chloride, and pyridine in the presence of anhydrous ether. (The substance described under this name by von Meyer [A., 1914, i, 999] is actually the corresponding *N*-derivative.) It is converted by phenylhydrazine in acetic acid solution (50%) into 4-cyano-1:3-diphenylpyrazole-5-carboxyphenylhydrazide,  $\text{Ph}\overset{\text{C}}{\underset{\text{N}-\text{NPh}}{\text{C}}}(\text{CN})\gg\text{C}\cdot\text{CO}\cdot\text{NH}\cdot\text{NHPh}$ , needles, m. p.  $215-216^\circ$ , which is

converted by prolonged treatment with *N*-sodium hydroxide solution into 4-carbamido-1:3-diphenylpyrazole-5-carboxyphenylhydrazide, m. p.  $269^\circ$ . The cyano-compound is oxidised by potassium permanganate in the presence of acetone to 4-cyano-1:3-diphenylpyrazole-5-carboxylic acid,  $\text{Ph}\overset{\text{C}}{\underset{\text{N}-\text{NPh}}{\text{C}}}(\text{CN})\gg\text{C}\cdot\text{CO}_2\text{H}$ , colourless needles,

m. p.  $216-217^\circ$  (decomp.), which is converted by sodium hydroxide solution (10%) into 1:3-diphenylpyrazole-4:5-dicarboxylic acid, m. p.  $197^\circ$  (decomp.). *Ethyl  $\gamma$ -imino- $\beta$ -cyano- $\alpha$ -keto- $\gamma$ -phenylbutyrate* is transformed by alcoholic ammonia into the corresponding amide,  $\text{NH}\cdot\text{CPh}\cdot\text{CH}(\text{CN})\cdot\text{CO}\cdot\text{CO}\cdot\text{NH}_2$ , lustrous leaflets, m. p.  $212-213^\circ$  (decomp.) after progressive decomposition above  $198^\circ$ , and by the calculated quantity of cold *N*-sodium hydroxide solution into the imino-lactone,  $\text{C}_{11}\text{H}_8\text{O}_3\text{N}_2$ , lustrous, quadratic leaflets, m. p.  $272^\circ$  (decomp.). The latter substance is transformed by phenylhydrazine into the phenylhydrazide,

$\text{NH}\cdot\text{CPh}\cdot\text{CH}(\text{CN})\cdot\text{CO}\cdot\text{CO}\cdot\text{NH}\cdot\text{NHPh}$ ,

matted needles, m. p.  $279-280^\circ$  (decomp.). *Ammonium  $\gamma$ -imino- $\beta$ -cyano- $\alpha$ -keto- $\gamma$ -phenylbutyrate*, m. p.  $181-183^\circ$  (decomp.), was obtained in one instance from the products of the action of water at  $60-70^\circ$  on the ester and was converted into the copper salt, a dark green, voluminous precipitate from which  *$\gamma$ -imino- $\beta$ -cyano- $\alpha$ -keto- $\gamma$ -phenylbutyric acid*, an unstable compound, m. p.  $132^\circ$  (decomp.), is isolated by the action of hydrogen sulphide in the presence of ether.

Benzoacetodinitrile is converted by oxalyl chloride in the presence of ether and pyridine into *oxalylbisbenzoacetodinitrile*,  $C_{26}H_{14}O_2N_4$ , m. p. 217—218° (decomp.).

*p*-Toluoacetodinitrile, ethoxalyl chloride, and pyridine in the presence of anhydrous ether give *ethyl  $\gamma$ -imino- $\beta$ -cyano- $\alpha$ -keto- $\gamma$ -p-tolylbutyrate*,  $NH_2C(C_6H_4Me) \cdot CH(CN) \cdot CO \cdot CO_2Et$ , long, colourless needles, m. p. 132—133° (decomp.), which is converted by phenylhydrazine into *4-cyano-1-phenyl-3-p-tolylpyrazole-5-carboxyphenylhydrazide*,  $C_{24}H_{19}ON_5$ , lustrous needles, m. p. 224—225°, and *4-carbamido-1-phenyl-3-p-tolylpyrazole-5-carboxyphenylhydrazide*,  $C_{24}H_{21}O_2N_5$ , small needles, m. p. 266—268°. Oxidation of the cyanohydrazide by potassium permanganate in the presence of acetone leads to the formation of *4-cyano-1-phenyl-3-p-tolylpyrazole-5-carboxylic acid*, microscopic needles, m. p. 208—209°. Ethyl  $\gamma$ -imino- $\beta$ -cyano- $\alpha$ -keto- $\gamma$ -p-tolylbutyrate is converted by alcoholic ammonia into  *$\gamma$ -imino- $\beta$ -cyano- $\alpha$ -keto- $\gamma$ -p-tolylbutyramide*, m. p. 195—196° (decomp.) after darkening and incipient decomposition at 175°, and by *N*-sodium hydroxide solution into the *imino-lactone*,  $C_{12}H_{10}O_3N_2$ , slender needles, decomp. 301°. Ammonium  $\gamma$ -imino- $\beta$ -cyano- $\alpha$ -keto- $\gamma$ -p-tolylbutyrate, m. p. 165—166° (decomp.), is obtained as in the case of the corresponding phenyl compound and is similarly transformed into the *copper* salt and the *free acid*, m. p. 149° (decomp.).

The compounds obtained by von Meyer (*loc. cit.*) from *p*-toluoacetodinitrile are to be regarded as *N*-derivatives.

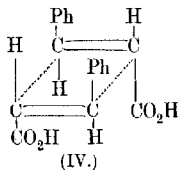

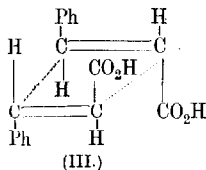

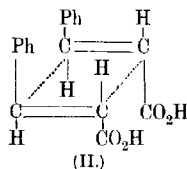

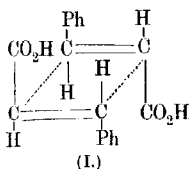

*C-Oxalylbisdiacetodinitrile*,  $C_{10}H_{10}O_2N_4$ , four-sided prisms which slowly become carbonised above 195°, is obtained from diacetodinitrile, pyridine, and oxalyl chloride in the presence of anhydrous ether.  
H. W.

**The Constitution of the Truxillic and Truxinic Acids and the Action of Sunlight on the Cinnamic Acids and their Salts.**  
A. W. K. DE JONG (*Ber.*, 1923, **56**, [B], 818—832).—The action of sunlight on the normal and acid salts of *trans*-cinnamic acid has been investigated, the material being spread evenly over glass plates placed in shallow wooden boxes and not further covered. Under these conditions, lithium *trans*-cinnamate gives  $\beta$ - and  $\epsilon$ -truxinic acids, the sodium and potassium salts yield only  $\beta$ -truxinic acid, whereas methyl *trans*-cinnamate gives  $\alpha$ -truxillic acid. Among salts of the bivalent metals, the stable strontium salt and the copper, cadmium, manganese, ferrous, and cobaltous salts do not give truxillic and truxinic acids.  $\beta$ -Truxinic acid is exclusively obtained from the magnesium and nickel salts and from the barium salt after desiccation at 100°. The metastable strontium and the stable barium salts yield  $\beta$ -truxinic and  $\epsilon$ -truxillic acids, whereas the metastable barium and the stable lead salts give  $\beta$ - and  $\delta$ -truxinic acids.  $\delta$ -Truxinic acid in large amount and only a small quantity of  $\beta$ -truxinic acid are obtained from the metastable lead salt, so that it does not appear improbable that the occurrence of the  $\beta$ -acid is due to the partial transformation of the salt into the stable form. Exclusive production of  $\epsilon$ -truxillic acid is not observed.

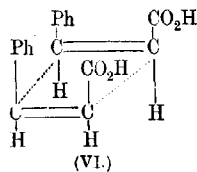

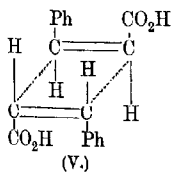

The strontium and barium salts after being heated during eight days do not yield  $\alpha$ -truxillic acid when illuminated; truxinic or truxillic acids are not obtained from the double salt derived from calcium benzoate and calcium *trans*-cinnamate.

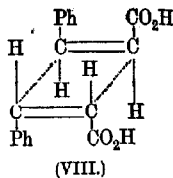

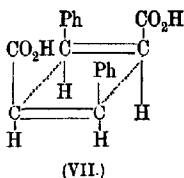

Among the hydrogen salts, the lithium and ammonium compounds yield  $\beta$ -truxinic and  $\alpha$ -truxillic acids; the production of the latter acid is probably due to the salts becoming moist and sticky, and thus converted into a mixture of free acid and normal salt.  $\beta$ -Truxinic acid is alone obtained from the strontium and barium compounds. The sodium and caesium salts yield  $\beta$ - and  $\delta$ -truxinic acids, whereas  $\beta$ -truxinic and  $\epsilon$ -truxillic acids are derived from the potassium compound.

The author seeks an explanation of the polymerisation of the cinnamic acids in the hypothesis that the cinnamic acid molecules are held by the partial valencies of the double bond in such a manner that the latter are always parallel to one another. In the case of the *trans*-cinnamic acid four possibilities present themselves as shown by the formulæ

The production of  $\alpha$ -truxillic (I),  $\beta$ -truxinic (II),  $\epsilon$ -truxillic, (III) and  $\delta$ -truxinic (IV) acids is thus readily explained. Considerations of symmetry show this property to decrease in the given sequence and the stability must consequently diminish in the same order. This is in good accord with the known properties of the  $\alpha$ - and  $\beta$ -cinnamic acids, and the non-occurrence of the other two possible forms. Similarly, four forms are possible for the *cis*-cinnamic acids as shown in the scheme :

The symmetry and consequently the stability diminish in the given order. The formulæ V, VI, and VII represent, therefore, the nuclei of the acids, m. p. 68°, 58°, and 42°, respectively.

Illumination of the normal calcium salt gives  $\beta$ -truxinic acid and a new acid, m. p. 214°, which is only formed in very small quantity.

The following salts of cinnamic acid are described. The normal strontium compound crystallises when its aqueous solution is rapidly cooled in small, metastable needles which rapidly pass in contact with the solution into larger needles of the stable salt. Similarly, metastable *barium* cinnamate ( $+2\text{H}_2\text{O}$ ) crystallises in lustrous, thin, hexagonal leaflets from its highly concentrated solution which pass into small needles of the stable form. The metastable form of lead cinnamate, small needles, is converted more slowly into the stable modification.

The following acid salts have not been described previously. They are all anhydrous. The *lithium* salt,  $\text{C}_9\text{H}_7\text{O}_2\text{Li}\cdot\text{C}_6\text{H}_5\text{O}_2$ , the *rubidium*, *cæsium*, *strontium*, and *barium* salts. The corresponding calcium salt could not be prepared. For the purposes of comparison, the following benzoates have been prepared; the *barium* salt,  $(\text{Ph}\cdot\text{CO}_2)_2\text{Ba}\cdot 2\text{Ph}\cdot\text{CO}_2\text{H}$ , small, slender needles; the *strontium* salt,  $(\text{Ph}\cdot\text{CO}_2)_2\text{Sr}\cdot\text{Ph}\cdot\text{CO}_2\text{H}$ , slender needles; the *calcium* salt,  $(\text{Ph}\cdot\text{CO}_2)_2\text{Ca}\cdot\text{Ph}\cdot\text{CO}_2\text{H}$ . The ratio of acid to normal salt is not affected in the two latter instances by the presence of an excess of acid.

H. W.

**The Dinaphthanthracene Series. V.** ERNST PHILIPPI and REINHARD SEKA [with MOLLY HAUSENBICHL] (*Monatsh.*, 1923, 43, 615—619; cf. A., 1921, i, 728).—Pyromellitic anhydride readily condenses with *p*-xylene at 75° in presence of aluminium chloride to give a mixture of 4:6-*di-p*-xylylisophthalic and 2:5-*di-p*-xylyltetraphthalic acids. The recrystallised mixture (m. p. 298°) is converted by concentrated sulphuric acid into 1:4:8:11-tetramethyl-5:7:12:14-dinaphthanthradiquinone, greenish-yellow needles, darkening at 340° and charring at 385° without melting. This substance does not give a vat colour with alkali hyposulphite, but on oxidation with nitric acid passes into 5:7:12:14-dinaphthanthradiquinone-1:4:8:11-tetracarboxylic acid (darkening at 250° and charring at 325°), which dyes cotton pale rose-red shades and, with hyposulphite, affords a deep red vat colour, the latter becoming blue in presence of alkali (cf. Seer, A., 1912, i, 571).

E. E. T.

**The Dinaphthanthracene Series. VI. ERNST PHILIPPI and REINHARD SEKA** [with WILHELM FIGDOR and RUDOLF NEMECZEK] (*Monatsh.*, 1923, **43**, 821—831; cf. preceding abstract, and Fairbourn, T., 1921, **119**, 1573).—Pyromellitic anhydride condenses with *o*-xylene in presence of aluminium chloride to give a mixture of 4:6-di-*mp*-dimethylbenzoylisophthalic and 2:5-di-*mp*-dimethylbenzoylterephthalic acids, separable into a sparingly soluble acid (m. p. 312°) and a soluble acid (m. p. 250°). The corresponding mixture of acid chlorides loses hydrogen chloride when treated with aluminium chloride, but no isolable compound results.

Pyromellitic anhydride and anisole condense to give a mixture (m. p. 200—250°) of 4:6-di-*p*-methoxybenzoylisophthalic and 2:5-di-*p*-methoxybenzoylterephthalic acids, which may be separated by crystallisation from water. The 2:5-acid (sparingly soluble) melts at 311°, the 4:6-acid (more soluble) at 285°, with previous discoloration. Neither acid is convertible by means of sulphuric acid into a dinaphthanthradiquinone.

Pyromellitic anhydride condenses with quinol dimethyl ether to give a poor yield of the two expected di-2:4-dimethoxybenzoylisophthalic and -terephthalic acids (green product, m. p. about 220°).

Anthracene-2:3-dicarboxylic anhydride and benzene on condensation give an ill-defined product, melting indefinitely at 130°, and giving, on oxidation, 2-benzoylanthraquinone-3-carboxylic acid, m. p. (indef.) 275°. Magnesium phenyl bromide converts anthracene-dicarboxylic anhydride into the corresponding diphenylphthalide derivative (yellow, m. p. 260°), and this, on oxidation, gives the corresponding anthraquinone derivative (yellow, m. p. 200°).

Bromination of dinaphthanthradiquinone at 300° gives a mixture of products, of which the isolable one is a dibromo-derivative, sintering at 358° and melting at 363°. Nitration of the diquinone gives a dinitro-derivative, darkening and charring at 380—400°. E. E. T.

**The Symmetric and Mixed Esters of Carboxycamphoracetic Acid and their Saponification Products.** A. HALLER and L. PALFRAY (*Compt. rend.*, 1923, **176**, 1193—1197).—The following esters of carboxycamphoracetic acid having the general

formula  $C_8H_{14} \begin{smallmatrix} \diagup \\ C(CO_2R')-CH_2-CO_2R \\ \diagdown \\ CO \end{smallmatrix}$  were prepared in the manner

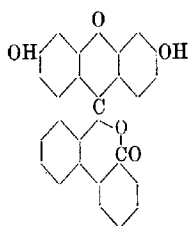

previously described (A., 1905, i, 601) by the action of the corresponding iodoacetic ester on the sodium camphorcarboxylic ester:—Diethyl ester, b. p. 199—200°/14 mm.,  $[\alpha]_D + 59.43^\circ$ ; phenyl(R)-methyl(R') ester, b. p. 233—235°/13 mm., m. p. 83°,  $[\alpha]_D + 41.38^\circ$ ; benzyl(R')methyl(R) ester, b. p. 265—270°/16 mm.,  $[\alpha]_D + 46.1^\circ$ . On saponification by alkalis or mineral acids, only the acetic ester (R) group is removed provided the temperature is kept below 150°, the carboxylic ester (R') group proving exceptionally stable. The above-mentioned diethyl ester furnishes therefore a carboxycamphoracetic acid of the constitution  $C_8H_{14} \begin{smallmatrix} \diagup \\ C(CO_2Et)-CH_2-CO_2H \\ \diagdown \\ CO \end{smallmatrix}$ ;

forming large crystals, m. p. 117—118°. The dimethyl ester similarly gives the corresponding monomethyl ester, m. p. 177—178°,

and the above phenyl methyl ester gives the same product. The benzyl methyl ester gives the benzylcarboxylate, which forms an uncrystallisable oil. The action of hydrochloric acid on the esters at 180–190° under pressure effects the hydrolysis of both ester groups with simultaneous elimination of carbon dioxide and forma-

tion of *camphoracetic acid*,  $C_8H_4 \begin{smallmatrix} \text{CH-CH}_2\text{-CO}_2\text{H} \\ \text{CO} \end{smallmatrix}$ , m. p. 84–86°,  $[\alpha]_D + 72.35^\circ$ . G. F. M.

#### Condensation of Diphenic Anhydride with Resorcinol.

FRITZ BISCHOFF and HOMER ADKINS (*J. Amer. Chem. Soc.*, 1923, 45, 1030–1033).—Diphenic anhydride and resorcinol are condensed by heating at 135–150° with zinc chloride, to give the 9-lactone of 2'-(3'' : 6'' : 9''-trihydroxyanthracyl)diphenyl-2-carboxylic acid (annexed formula), an amorphous, ruby-red glass, which reacts with bromine in alcoholic solution to give the corresponding 2'' : 4'' : 5'' : 7''-tetrabromo-derivative, a pinkish-yellow solid. Both these compounds give acetylated

products which are insoluble in alkalis.

W. S. N.

**The Sodium Salts of Phenolphthalein.** HENRY BASSETT and PHILIP HALTON (*T.*, 1923, 123, 1291–1304).

**The Molecular Configurations of Polynuclear Aromatic Compounds.** III. **Diphenyl-3 : 5 : 3' : 5'-tetracarboxylic Acid.** HAROLD BURTON and JAMES KENNER (*T.*, 1923, 123, 1043–1045).

**Derivatives of 2 : 4-Dinitrobenzaldehyde.** III. THOMAS B. DOWNEY and ALEXANDER LOWY (*J. Amer. Chem. Soc.*, 1923, 45, 1060–1065; cf. *A.*, 1920, i, 440; 1921, i, 337).—A number of Schiff bases derived from 2 : 4-dinitrobenzaldehyde are described; the intermediate condensation product with *o*-tolidine is formed in a 95% aqueous alcoholic solution, but the Schiff base is produced in the presence of acetic acid. A number of triphenylmethane derivatives have been prepared by the condensation of 2 : 4-dinitrobenzaldehyde (1 mol.) with a tertiary alkylated aromatic amine or substituted aromatic amine or phenolic substance (2 mols.).

The additive compound of 2 : 4-dinitrobenzaldehyde and *o*-tolidine,  $C_6H_3(NO_2)_2 \cdot CH(OH) \cdot NH \cdot C_6H_3Me \cdot C_6H_3Me \cdot NH_2$ , deep purple plates, m. p. 232°, is converted by acetic acid in acetone solution into 2 : 4-dinitrobenzylidene-*o*-tolidine, yellowish-red crystals, m. p. 282° (decomp.), which reacts with acetic anhydride to give 2 : 4-dinitrobenzylideneacetyl-*o*-tolidine, orange-yellow needles, m. p. 231.5°. The following Schiff bases are also described: 2 : 4-dinitrobenzylidene-*o*-dichloroaniline,  $C_6H_3(NO_2)_2 \cdot CH : N \cdot C_6H_3Cl_2$ , bright orange plates, m. p. 185°; 2 : 4-dinitrobenzylidene-*o*-chloroaniline, yellow needles, m. p. 167.5°; 2 : 4-dinitrobenzylidene-*p*-chloroaniline, yellow needles, m. p. 161.5°; 2 : 4-dinitrobenzylidene-*p*-aminoazobenzene, red prisms, m. p. 229°. The following triphenylmethane derivatives

described: 2'' : 4''-dinitro-4 : 4'-dihydroxytriphenylmethane,  $H_3(NO_2)_2 \cdot CH(C_6H_4 \cdot OH)_2$ , pale yellow solid, m. p. 204°, which gives a tetrabromo-derivative, yellow needles, m. p. 234°; 4 : 4'-dinitro-2 : 4'-dinitrotriphenylmethane, m. p. 190.5°; op-dinitrophenyl-2 : 4'-cresolmethane, m. p. 200.5°; op-dinitrophenyl-di-guaiacolmethane, m. p. 221°; op-dinitrobenzylidenedi-4-salicylic acid, m. p. 138.5°, all of which are yellow solids. 2'' : 4''-Dinitro-4 : 4'-diethylaminotriphenylmethane, yellow needles, m. p. 151.5°; the corresponding bisdiethylamino-compound, an unstable, dirty green solid, and the benzylethylamino-compound, a brownish-yellow solid. The last three compounds give colour bases and dyes. The formation of op-dinitrophenyl-di-4'-resorcinolmethane, yellow, amorphous solid, chars above 280°, red calcium salt, is accompanied by the reduction of 3 : 6-dihydroxy-9-op-dinitrophenylxanthen, a yellowish solid, amorphous solid, which chars above 280°, which is also formed the condensation is carried out in the presence of zinc chloride at 5—130°, or of sulphuric acid at 60°; it yields a calcium salt and a tetrabromo-derivative, red prisms, decomp. 290° (cf. *J.S.C.I.*, 1923, 490A). W. S. N.

**The Isomerism of the Oximes. XI. Carbethoxy-derivatives.** OSCAR LISLE BRADY and GERALD PATRICK McHUGH *ibid.*, 1923, 123, 1190—1198).

**Peroxides of Monoximes.** R. CIUSA and E. PARISI (*Gazzetta*, 1923, 53, i, 143—149).—*m*-Nitrobenzaldoxime peroxide, obtained either by passing a slow current of nitrogen trioxide into an ethereal solution of the oxime or by oxidising the latter by means of amyl trite, has m. p. 131°, as stated by Ponzio (*A.*, 1906, i, 593), and at 105°, as given by Minunni and Ciusa (*A.*, 1906, i, 187), or 124°, as given by Franzen and Zimmermann (*A.*, 1906, i, 388). The action of nitrogen trioxide on the oxime dissolved in ether yields, in addition to the peroxide, (1) a substance, probably *m*-nitrobenzonitric acid,  $NO_2 \cdot C_6H_4 \cdot C(NO_2) \cdot N \cdot OH$ , which reddens sodium carbonate solution and is converted by this reagent into a mixture of di-*m*-nitrobenzildioxime peroxide, m. p. 184°, and 3 : 4-di-*m*-nitrophenylfurazan, m. p. 168°; (2) *m*-nitrobenzoic acid; (3) a compound, m. p. 147—150°, which is identical with that described by Bamberger and Scheutz (*A.*, 1901, i, 548) as *m*-nitrobenzenyloxime, but is more probably 3 : 4-di-*m*-nitrophenylfurazan; (4) di-*m*-nitrobenzildioxime. *m*-Nitrobenzaldoxime peroxide is also obtainable in small proportion by oxidising the oxime with either potassium ferricyanide or sodium hypochlorite.

When heated at 50° in suspension in benzene, the peroxide yields di-*m*-nitrobenzaldoxime peroxide, 3 : 4-di-*m*-nitrophenylfurazan, *m*-nitrobenzoic acid in large proportion, and a small proportion of a compound which crystallises in colourless, rhombic plates, m. p. 124°, but has not yet been identified. T. H. P.

**Dehydration of Phenylhydrobenzoin.** STEFAN DANILOV (*J. Russ. Phys. Chem. Soc.*, 1917, 49, 282—289).—The dehydration with 10% sulphuric acid of phenylhydrobenzoin results in a mixture of

triphenylvinyl alcohol and triphenylacetaldehyde, in the proportions 4:1. Garder (*Bull. Acad. roy. Belg.*, [iii], 34, 94), who used phosphoric oxide for the dehydration, obtained the same products, but erroneously identified the second of them as triphenylethylene oxide. Triphenylacetaldehyde has been described by Schmidlin (A., 1910, i, 368) as a substance of m. p. 218°, but it appears that he was mistaken in considering the substance he obtained as triphenylacetaldehyde, and the compound now obtained melts at 105–106°. Oxidation with chromic anhydride converted it into a mixture of triphenylacetic acid and triphenylcarbinol, whilst alcoholic potash gave triphenylmethane. *Triphenylacetaldoxime*, colourless rhombic prisms, m. p. 190°, and the *semi-carbazone*, m. p. 223°, and *phenylhydrazone*, m. p. 142°, of triphenylacetaldehyde were prepared. By the reduction with sodium amalgam of the phenylhydrazone, triphenylethylamine, m. p. 130–131°, was obtained. Aluminium amalgam converts the aldehyde into *triphenylethanol*, m. p. 110–111°, the *phenylurethane* of which m. p. 205–206°, was prepared. Phosphoric oxide acts on the aldehyde to give triphenylvinyl alcohol, showing that a tendency exists for the aldehyde to isomerise to a ketonic form. R. T.

#### The Behaviour of certain Aromatic Hydroxyaldehydes.

A. WINDAUS and H. SCHIELE (*Ber.*, 1923, 56, [B], 846–848).—Benzaldehyde is converted by iodine and dilute potassium hydroxide solution at the atmospheric temperature into benzoic acid in good yield. Under similar conditions, salicylaldehyde loses the aldehydic group as formic acid and yields iodophenol; it is preferable to use an excess of iodine which causes the almost exclusive production of 2:4:6-tri-iodophenol, whereas a mixture of iodophenols is otherwise produced. The behaviour of *p*-hydroxybenzaldehyde is similar. *m*-Hydroxybenzaldehyde, on the other hand, gives an *iodo-m-hydroxybenzoic acid*, needles, m. p. 219–220° (*methyl ester*, colourless needles, m. p. 49°), in which the position of the iodine atom has not been established. 6-Hydroxy-*m*-tolualdehyde and  $\beta$ -naphthol-1-aldehyde behave similarly to *o*- and *p*-hydroxybenzaldehydes, the former giving 3:5-di-iodo-4-hydroxytoluene, m. p. 61–61.5°, and the latter yielding  $\alpha$ -iodo- $\beta$ -naphthol, m. p. 92.5°.

Catalytic hydrogenation of salicylaldehyde dissolved in glacial acetic acid at the atmospheric temperature and pressure in the presence of spongy platinum gives *o*-cresol; under similar conditions,  $\beta$ -naphthol-1-aldehyde is converted into  $\alpha$ -methyl- $\beta$ -naphthol. H. W.

**Isomerism of Thioaldehydes.** EMIL FROMM and CARLTHE SCHULTIS (*Ber.*, 1923, 56, [B], 937–947).—Baumann and Fromm have shown in a series of communications that thioaldehydes occur usually in trimeric, but also in other polymeric forms, and that under the most varied conditions it is possible to obtain only single trithioformaldehyde or trithioacetone, whereas many other aldehydes give two isomeric trithioaldehydes. The substances have been regarded as cyclic sulphides, and their occurrence in different modifications has been explained in accordance with the principle

*cis-trans*-isomerism. This conception appeared adequate until Hinsberg (A., 1912, i, 546; 1913, i, 818; 1914, i, 185, 797) announced discovery of a second  $\beta$ -trimethylene trisulphide, and of a third trithiobenzaldehyde, the existence of which is not explicable on the theory of stereoisomerism. A repetition of Hinsberg's work has shown that the compounds described by him do not exist. The crude product obtained by the action of hydrogen sulphide on formaldehyde in the presence of hydrochloric acid has the same melting point ( $216^\circ$ ) as pure trimethylene trisulphide. The compounds, however, are not identical. The crude material is a highly polymerised disulphide of the type

which loses a small amount of sulphur when recrystallised and yields pure trimethylene trisulphide, m. p.  $216^\circ$ , in accordance with the scheme:  $(\text{H}_2\text{CS})_2 + \text{S} \rightarrow x/3(\text{H}_2\text{CS})_3 + \text{S}$ . It is converted by concentrated hydriodic acid into the highly polymerised di-mercaptan,  $\text{HS-CH}_2\text{-S-CH}_2\text{-S} \dots \text{CH}_2\text{-S-CH}_2\text{-SH}$ , decomp.  $247^\circ$ , which loses small amounts of hydrogen sulphide when recrystallised and gives trimethylene trisulphide, m. p.  $216^\circ$ . The latter cannot be transformed by any known method into the mercaptan or disulphide. The products also behave differently when oxidised. The crude material gives a highly polymerised sulphoxide,

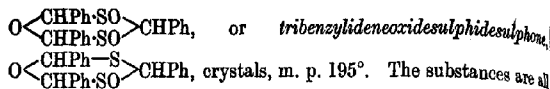

which is reduced to the mercaptan, decomp.  $247^\circ$ , whereas the trimethylene trisulphide yields the corresponding sulphoxide,

comp.  $270^\circ$ , which, when reduced with hydriodic acid, gives trimethylene trisulphide, m. p.  $216^\circ$ , and its *di-iodide*,  $\text{C}_3\text{H}_6\text{S}_3\text{I}_2$ , small, dark red leaflets, m. p.  $100-110^\circ$ , and *tetraiodide*,  $\text{C}_3\text{H}_6\text{S}_3\text{I}_4$ , dark violet prisms, decomp.  $100-105^\circ$ , but not the substance, comp.  $247^\circ$ .

With tribenzylidene trisulphides the relationships are more complicated but Hinsberg's main error appears to consist in the supposition that the pure  $\alpha$ - and  $\beta$ -varieties yield different oxidation products when treated with hydrogen peroxide. This is, however, possible since in the presence of even a deficiency of the reagent the  $\alpha$ -form is converted into the  $\beta$ -modification and the oxidation products are therefore necessarily derived from the latter. The products obtained by treating tribenzylidene trisulphide with small amounts of hydrogen peroxide are *tribenzylidene trisulphide*,  $\text{SO} \begin{array}{c} \text{CHPh} \\ \text{CHPh} \end{array} \text{SO} > \text{CHPh}$ , small needles, m. p.  $240^\circ$ , *tribenzyl-*

*idene trisulphone*,  $\text{SO}_2 \begin{array}{c} \text{CHPh} \\ \text{CHPh} \end{array} \text{SO}_2 > \text{CHPh}$ , a white, chalky powder which does not melt below  $340^\circ$  (the sodium salt,  $\text{C}_{21}\text{H}_{17}\text{O}_6\text{S}_3\text{Na}$ , potassium salt,  $\text{C}_{21}\text{H}_{17}\text{O}_6\text{S}_3\text{K}$ , additive compound with pyridine,  $\text{C}_{21}\text{H}_{18}\text{O}_6\text{S}_3\text{C}_5\text{H}_5\text{N}$ , slender needles, and the *dimethyl* derivative, m. p.  $248^\circ$ , are described), and *tribenzylideneoxocidedisulphoxide*,

The substances are all stable towards aqueous solutions of alkali hydroxides, by means of which they can be separated from one another. Since this treatment also causes the production of benzaldehyde and sulphur dioxide, there are always components of the crude product which are unstable towards alkali, but have not been investigated further. The tetroxide and pentoxide which have been described by Hinsberg are mixtures of these three or four products. Reduction of the trisulphoxide by hydriodic acid gives a product which usually contains iodine and has m. p.  $180-215^{\circ}$  according to the degree of purity. When recrystallised, it yields pure  $\beta$ -tribenzylidene trisulphide, m. p.  $216^{\circ}$ . The product is invariably crude  $\beta$ -trithiobenzaldehyde and not the new  $\delta$ -isomeride, as assumed by Hinsberg.

If  $\alpha$ - or  $\beta$ -tribenzylidene trisulphide is oxidised with a large excess of hot hydrogen peroxide, a product, decomp.  $295^{\circ}$ , is obtained which, in consequence of its insolubility, cannot be recrystallised. It is a mixture which is resolved by treatment with aqueous alkali hydroxide solution into tribenzylidenetrisulphide, tribenzylideneoxidedisulphoxide, benzaldehyde, and sulphur dioxide.

H. W.

**The Oxidation of 1:3-Dimethylcyclohexan-4-one, and the Synthesis of cyclopentane Diketones.** MARCEL GODCHOT (*Compt. rend.*, 1923, 176, 1151-1153).—The oxidation of 1:3-dimethylcyclohexan-4-one with cold 3% aqueous permanganate furnished a 70% yield of  $\delta$ -acetyl- $\gamma$ -methylvaleric acid together with a small amount of  $\beta$ -methyladipic acid formed by the further oxidation of the ketonic acid. The  $\delta$ -acetyl- $\gamma$ -methylvaleric acid is a colourless liquid, b. p.  $177^{\circ}/20$  mm., with  $n_D^{20}$  1.4599, and  $d_4^{20}$  1.078. Its semicarbazone melts at  $136^{\circ}$ , and the ethyl ester boils at  $130^{\circ}/18$  mm., and has  $d_4^{17}$  0.9715, and  $n_D^{17}$  1.4334. The internal condensation of this ester by means of sodium ethoxide gave a 75% yield of a  $\beta$ -diketone, 2-acetyl-1-methylcyclopentan-3-one,  $\begin{array}{c} \text{CH}_2-\text{CO} \\ | \\ \text{CH}_2-\text{CHMe} \end{array} > \text{CH}:\text{COMe}$ , an agreeably smelling liquid, b. p.  $89-90^{\circ}/12$  mm., and having  $d_4^{16}$  1.029, and  $n_D^{16}$  1.4756. It gives an intense violet coloration with ferric chloride, and forms with semicarbazide a disemicarbazone,  $\text{C}_{10}\text{H}_{18}\text{O}_2\text{N}_4$ , m. p.  $240^{\circ}$  (decomp.), and a carbamylpyrazole, m. p.  $120^{\circ}$ , arising from the anhydriation of the monosemicarbazone. On treatment with sodium and methyl iodide, the  $\beta$ -diketone was converted into 2-acetyl-1:2-dimethylcyclopentan-3-one, a colourless liquid, b. p.  $99-100^{\circ}/14$  mm., and having  $d_4^{17}$  1.020, and  $n_D^{17}$  1.4585. Its monosemicarbazone melts at  $240^{\circ}$ . On treatment with aqueous alkali hydroxide, it is converted into  $\delta$ -acetyl- $\gamma$ -methylhexoic acid, b. p.  $164^{\circ}/10$  mm., with  $d_4^{15}$  1.055, and  $n_D^{15}$  1.4631; the ethyl ester has b. p.  $134-135^{\circ}/13$  mm.,  $d_4^{13}$  0.9865, and  $n_D^{13}$  1.4488.

G. F. M.

**Action of Ammonium Cyanide on Diketones.** H. D. DAKIN and C. R. HARRINGTON (*J. Biol. Chem.*, 1923, 55, 487—494).—A study of the action of ammonium cyanide on  $\alpha$ -diketones, with a view to the synthesis of homologues of diaminosuccinic acid, has shown that the reaction does not result, as expected, in the formation of aminonitriles, but usually leads to a fission of the carbon chain between the two carbonyl groups. Thus, benzil is converted practically quantitatively into benzamide and benzaldehyde cyanohydrin, the same products being also formed by the action of ammonia on benzil dicyanohydrin; anisil, piperil, and furil undergo analogous decompositions; *m*-dinitrobenzil yields *m*-nitrobenzamide and an oil which is probably a condensation product between *m*-nitrobenzaldehyde or its cyanohydrin and dinitrobenzil, and is converted into a glyoxaline derivative when heated with sodium hydroxide and acidified; diacetyl and phenylglyoxal appear to give glyoxaline derivatives. The following ketones are practically unaffected by ammonium cyanide: benzoin, distyryl ketone, benzoylacetone. E. S.

**The Electrolytic Oxidation of Benzene to *p*-Benzoquinone, and the Electrolytic Reduction of Quinone.** A. SEYEWETZ and G. MIRON (*Bull. Soc. chim.*, 1923, [iv], 33, 449—459).—A study was made of the conditions governing the electrolytic oxidation of benzene with the object of securing a maximum yield of *p*-benzoquinone. The optimum conditions whereby a yield of 65% of *p*-benzoquinone was obtained were found to lie within very narrow limits, and are summarised as follows: Electrodes of pure lead with a very homogeneous surface, separated by a diaphragm of porous pot unattackable by sulphuric acid. A current density of 4 amperes per sq. decm., under 3.2—3.5 volts. An electrolyte consisting of a solution containing 25% of sulphuric acid, 33% of acetic acid, with which is emulsified two-thirds of its volume of benzene in presence of 1.0—1.5% of finely divided lead sulphate as catalyst. The temperature must be maintained at 24°, and as soon as the benzene contains 1% of benzoquinone in solution it must be transferred from the anodic compartment to the cathode, otherwise a destruction of the *p*-benzoquinone commences, which rapidly diminishes the yield. The emulsion is produced by means of a helicoid stirrer rotating at 1,200 revolutions per minute inside the anodic compartment. The yield of *p*-benzoquinone rapidly falls with rise in temperature, and becomes zero at 55°. Traces of silica dissolved in the electrolyte cause a notable decrease in the yield. The reduction of the *p*-benzoquinone to quinol when the benzene solution is transferred to the cathodic compartment is practically quantitative. The optimum temperature is 40°, and the presence of 1% of vanadic acid as catalyst is advantageous. The quinol is dissolved by the aqueous electrolyte as it is formed, and the concentration can be allowed to increase to the saturation point without any disadvantage. The benzene, thus freed from *p*-benzoquinone is then returned to the oxidising cell and the process is thus rendered continuous. G. F. M.

**Synthesis of 4-Hydroxy-1 : 2-dimethylantraquinone.**  
 ARTHUR FAIRBOURNE and JOHN MILDRED GAUNTLETT (T., 1923,  
 123, 1137—1139).

**A New Class of Free Organic Radicles. II.** ROLAND SCHOLL [with HERBERT HÄHLE] (*Ber.*, 1923, 56, [B], 918—936; cf. A., 1921, i, 872).—Further investigation of the benzoyloxanthronyls has led the authors to a somewhat modified conception of their constitution. They are now regarded as members of a class of nitrogen-free organic radicles which were hitherto without analogues. They are distinguished from the triarylmethyls and the metallic ketyls by their slight sensitiveness to free oxygen and, in particular, by their ability to react with three atoms of bromine or to acquire three hydroxyl groups when titrated with permanganate until colourless. They appear to behave as trivalent radicles, but this is only apparent, since only two of the three equivalents of bromine or hydroxyl are retained, whereas the third removes the hydroketyl hydrogen in the second phase of the reaction in the form of hydrogen bromide or water, so that ultimately only one valency is saturated. In reality, therefore, they are univalent radicles. This is directly shown by the reaction with permonosulphuric acid, whereby only one hydroxyl group is introduced. Incidentally, this group also indirectly removes the hydroketyl hydrogen as water, so that ultimately in the final product one valency less is saturated than in chlorobenzoyloxanthronyl. Both processes, however, are characteristic of a univalent radicle. Towards chromic acid, the oxanthronyls appear to behave as bivalent radicles, probably as a consequence of the formation of peroxides.

The benzoyloxanthronyls are, however, univalent radicles of a peculiar type, and contain the characteristic arrangement of atoms indicated in the annexed formula. The hydrogen atom closes an internally-complex, seven-membered ring and shares its affinity with the two carbonyl oxygen atoms, so that these make demands on the two radicle-carbon atoms intermediate between those of carbonyl oxygen atoms and ordinary hydroxy-oxygen. The affinity of the free radicle valency is therefore not concentrated on a single trivalent carbon atom as in the triaryl-methyls or the simple metallic ketyls, but is distributed, generally in a non-uniform manner, over two carbon atoms. The benzoyloxanthronyls therefore contain two carbon atoms which may be regarded as together being septavalent. They are distinguished from the "true" carboxylic acids according to the conception of Hantzsch by their radicle nature, and before all by the firmness of retention and non-ionisability of the hydrogen atom.

1-*p*-Chlorobenzoyl-9-oxanthronyl is prepared according to the method of Schaarschmidt (A., 1915, i, 566, 696; 1916, i, 408) by treatment of 1-*p*-chlorobenzoylantraquinone with aluminium bronze and concentrated sulphuric acid, but satisfactory results are only obtained if the pure ketone is used as initial material. Reduction can also be effected with stannous chloride and glacial

acetic acid or by ferrous sulphate in glacial acetic and hydrochloric acids. The molecular weight of the substance in freezing nitrobenzene corresponds with the simple formula,  $C_{21}H_{13}O_3Cl$ . The sulphate,  $C_{21}H_{13}O_3Cl \cdot 2H_2SO_4$  (cf. Schaarschmidt, *loc. cit.*), has now been isolated in the homogeneous condition in the form of dark emerald-green needles. Oxygen does not appear to react with the compound dissolved in nitrobenzene in the dark during four hours at the atmospheric temperature, and attacks it but slowly when the temperature is raised. In daylight, the substance disappears, but only twice as rapidly as when it is illuminated under carbon dioxide. In either case, the reaction is one of dehydrogenation of the *p*-chlorobenzoyloxanthronyl to *p*-chlorobenzoylanthraquinone. Under carbon dioxide, the oxanthronyl itself, and possibly the solvent, act as hydrogen acceptors, whereas in the presence of oxygen this rôle is played by the gas and the primarily formed hydroperoxide, the presence of which cannot be established at any stage of the reaction.

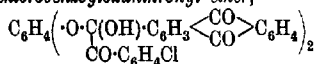

The product of the action of bromine on *p*-chlorobenzoyloxanthronyl has been isolated by cautiously adding the latter to an excess of the halogen. Analyses of the not perfectly homogeneous product indicate the composition  $C_{21}H_{11}O_3ClBr_2$ . The product is transformed into bromine and *p*-chlorobenzoylanthraquinone when heated with water or acetic acid.

*p*-Chlorobenzoyloxanthronyl dissolved in nitrobenzene can be sharply titrated with acid permanganate solution, three equivalents of oxygen being required for the decolorisation of each molecule; the primary product has not been isolated, but chlorobenzoylanthraquinone and iodine are obtained when it is treated with potassium iodide and steam.

Titration of *p*-chlorobenzoyloxanthronyl with chromic acid can be effected when the former is dissolved in nitrobenzene and the latter in glacial acetic acid, or both are dissolved in concentrated sulphuric acid. In either case, one atomic proportion of oxygen is required for each molecule of the ketone.

*p*-Chlorobenzoyloxanthronyl is rapidly converted by nitric acid or nitrogen peroxide into *p*-chlorobenzoylanthraquinone; on the other hand, it appears to be stable in nitrobenzene solution towards nitric oxide.

*Quinolbis-p-chlorobenzoyloxanthronyl ether*,

is prepared as a white powder with a pale yellow tint by the action of *p*-benzoquinone on *p*-chlorobenzoyloxanthronyl in the presence of glacial acetic acid. It is perfectly stable at the atmospheric temperature even in the presence of air. It begins to dissociate at about  $100^\circ$ , and at  $130$ – $140^\circ$  exhibits the dark bluish-violet colour proper to the oxanthronyl, whilst *p*-benzoquinone sublimes. In solution, dissociation commences at the atmospheric temperature so that they show the same colours as very dilute solutions of the radicle itself. The addition of the quinone appears to take place in two stages; the union of molecular proportions of the components

occurs slowly, after which the second molecule of the radicle is rapidly added.

H. W.

**Ethyl Fenchylxanthate.** SERGEI S. NAMETKIN and (MILE) A. S. SELIVANOVA (*J. Russ. Phys. Chem. Soc.*, 1917, **49**, 417—425).—Ethyl fenchylxanthate gives on decomposition a mixture of *cyclo*-fenchene and fenchene. Pure fenchyl alcohol is shown to melt at 49°, not at 45°, as is generally accepted, the lower m. p. being due probably to the presence of an isomeric isofenchyl alcohol.

R. T.

**A Method for Resolving some Racemic Alcohols into their Optically Active Components.** A. WINDAUS, F. KLÄNHARDT, and R. WEINHOLD (*Z. physiol. Chem.*, 1923, **126**, 308—312).—The double compound of the alcohol with digitonin is formed (cf. this vol., i, 590), and on recrystallising this compound resolution is obtained, and the alcohol is then obtained free from digitonin by distillation in a vacuum or in steam. In this way, resolution has been effected of *dl*- $\alpha$ -terpineol, *dl*- $\alpha$ -tetrahydro- $\beta$ -naphthol, and of carvomenthol. Phenylmethylcarbinol, on the other hand, remained inactive.

W. O. K.

**Homologues of Camphor.** I. S. S. NAMETKIN and (MILE) ANNA M. CHUCHRIKOVA (*J. Russ. Phys. Chem. Soc.*, 1918, **50**, 254—263).—6-Methylcamphor, b. p. 213—213.5°/767 mm., m. p. 168—168.5, is synthesised in the following way. Methylfenchyl alcohol is prepared by the action of magnesium methyl iodide on fenchene, and converted into methylfenchene by dehydration with potassium hydrogen sulphate. Boiling with glacial acetic acid converts methylfenchene into *acetylmethylisoborneol*, b. p. 110°/14 mm.,  $d_4^{20}$  0.9714,  $n_D^{20}$  1.4634, and this, on hydrolysis, gives *methylisoborneol*, m. p. 191—192°, b. p. 219—219.5°/753 mm. Its *phenylurethane*, m. p. 101—102°, and *hydrogen phthalate*, m. p. 167—168°, were prepared. By means of strong nitric acid methylisoborneol is converted into methylcamphor, the *semicarbazone* of which, m. p. 251°, and *oxime*, m. p. 131—132°, were prepared. *Methylborneol*, b. p. 219—220°/758 mm., m. p. 183—184°, was prepared by acting on methylcamphor with sodium in alcoholic solution, and its *phenylurethane*, white needles, m. p. 108°, and *hydrogen phthalate*, m. p. 186°, were prepared. Oxidation of methylcamphor with alkaline potassium permanganate gives *methylciscamphoric acid*, m. p. 185—186°, which on heating is changed into the *anhydride*, m. p. 205—206°.

R. T.

**Catalytic Oxidations with Platinum Black.** I. Oxidation of *Buchu-camphor*. GUIDO CUSMANO (*Gazzetta*, 1923, **53**, i, 153—164).—When exposed in ethereal solution to the action of oxygen or air in presence of platinum black, *buchu-camphor* is rapidly converted principally into four compounds, forming two pairs of related compounds: (a)  $C_{10}H_{18}O_4$  (I) and  $C_{10}H_{16}O_4$  (II); these compounds, previously unknown, retain the *cymene* skeleton, and the first of them is readily converted into the second, which exhibits the phenolic behaviour of *buchu-camphor* and is named

provisionally oxybuchu-camphor. (b)  $C_{10}H_{18}O_4$  (III) and  $C_{10}H_{14}O_3$  (IV). Compound (IV) is an acid and was described by Semmler and Mackenzie (A., 1906, i, 373), who obtained it by the internal dehydration of an open-chain acid occurring among the products of oxidation of buchu-camphor by means of permanganate:

this open-chain acid may possibly represent an intermediate stage in the formation of compound (IV) by the action of lead peroxide, in the presence of dilute sulphuric acid, on compound (III), to which is ascribed the formula  $OH \cdot CHMe \cdot CH_2 \cdot CH_2 \cdot CHPr^s \cdot CO \cdot CO_2H$ . This action of lead peroxide results also, at the same time, in elimination from acid (III) of carbon dioxide, with formation of another acid, which may have either the formula  $OH \cdot CHMe \cdot CH_2 \cdot CH_2 \cdot CHPr^s \cdot CO_2H$ , or a lactonic or ketonic structure. In addition to the above four products, the oxidation of buchu-camphor by oxygen in presence of platinum black yields small proportions of an oxythymoquinone and of another compound, not yet characterised.

The compound  $C_{10}H_{18}O_4$  (I) crystallises in colourless, irregularly hexagonal laminae of vitreous lustre, m. p.  $126^\circ$  (decomp.).

*Oxybuchu-camphor*,  $C_{10}H_{16}O_3$ , formed from the preceding compound either by heating it at its melting point or by decomposing potassium salt by means of carbon dioxide, crystallises in colourless, transparent rhombs, m. p.  $75-76^\circ$ , has a faint, pleasant odour resembling that of thymol, volatilises unchanged, and in alcoholic solution gives a violet-black coloration with ferric chloride.

The acid,  $C_{10}H_{18}O_4$  (III, see above), forms long, colourless, prisms, acicular crystals containing water of crystallisation, which is lost in a desiccator. It is monobasic and forms crystalline ammonium and barium salts and a sparingly soluble silver salt.

For compound (IV), even when prepared as described by Semmler and Mackenzie (*loc. cit.*), the m. p.  $190^\circ$  is found, these authors giving p.  $182^\circ$ . T. H. P.

**Chemical Actions of Light.** G. SCAGLIARINI and GIUSEPPINA ADAMI (*Gazzetta*, 1923, 53, i, 135-139).—The indirect auto-oxidations of certain compounds have been investigated.

Fenchone and toluene, exposed for some months to the action of light in presence of oxygen and water, yielded carbon dioxide, benzoic and acetic acids. Under similar conditions, fenchone in alcohol gave carbon dioxide, acetic acid, a small proportion of oxalic acid, and a compound, b. p.  $83^\circ$ , containing 49.39% C and 11.32% H. Pinene and oxalic acid yielded a large proportion of resin, together with acetic acid.

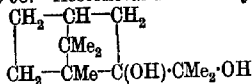

Acetone and geraniol gave a compound,

a liquid, b. p.  $208-210^\circ/14$  mm.,  $d_4^{20} 0.96$ . Acetone and menthol

gave the compound  $\begin{smallmatrix} CHMe \cdot CH_2 \cdot C(OH) \cdot CMe_2 \cdot OH \\ CH_2 \cdot CH_2 - CH \cdot CHMe_2 \end{smallmatrix}$ , b. p.  $197-$

200°/15 mm.,  $d$  0.95. Acetone and borneol yielded the compound

b. p. 160°/20 mm.,  $d$  0.99.

T. H. P.

**The Action of Hypochlorous Acid on Bornylene.** GEORGE GERALD HENDERSON and JOHN ALEXANDER MAIR (T., 1923, 1155—1161).

**Pinocamphane.** S. S. NAMETKIN and ANNA JARZEV (Ber 1923, 56, [B], 832—833).—Pinocamphone is converted by hydrazine hydrate at 190—200° into the corresponding *hydrazone*, colourless liquid of unpleasant odour, b. p. 134—135°/22 mm  $d_{20}^{20}$  0.9917,  $n_D^{20}$  1.5155, which is transformed by potassium hydroxide in the presence of platinum on fused clay or by sodium ethoxide, at 170—180° into *pinocamphane* (annexed formula), b. p. 163.5—164°/747 mm., 164.5—165°/763 mm  $d_{20}^{20}$  0.8558,  $n_D^{20}$  1.4611. The product does not appear to be identical with the dihydropinene obtained previously by the authors by the catalytic hydrogenation of *l*- $\alpha$ -pinene by Sabatier's method.

H. W.

**West Australian "Sandalwood Oil."** B. SANJIVA RAO and J. J. SUDBOROUGH (J. Ind. Inst. Sci., 1923, 5, 163—176).—The so-called West Australian sandalwood oil is derived from a tree (*Fusanus spicatus*, R.Br.) quite different from *Santalum alba* Linn., from which genuine East Indian sandalwood oil is obtained. It has  $d$  15/15°, 0.957—0.972;  $n_D^{25}$  1.5019—1.510;  $[\alpha]_D^{25}$  -0.2° to -7.7°; total alcohols as santalol ( $\text{C}_{15}\text{H}_{24}\text{O}$ ), 69.3—80.0%; esters as santalyl acetate, 2.3—6.5%; acid value, 2.4—5. The alcohols present are isomeric with the two santalols present in East Indian oil and have been termed  $\alpha$ - and  $\beta$ -fusanols. The fusanols yield hydrogen phthalates and phenylurethanes. The fact that they react much more slowly than the santalols with phthalic anhydride indicates that they are probably secondary, not primary alcohols. From their molecular refractions it is probable that the fusanols are bicyclic compounds containing two olefine linkages.  $\alpha$ -Fusanol,  $\text{C}_{15}\text{H}_{24}\text{O}$ , has b. p. 146—149°/5 mm.,  $d_{15}^{15}$  0.9775,  $n_D^{25}$  1.50,  $[\alpha]_D^{25}$  +5.7°.  $\beta$ -Fusanol has b. p. 153—155°/5 mm.,  $d_{15}^{15}$  0.97,  $n_D^{25}$  1.5100,  $[\alpha]_D^{25}$  +26°.

H. C. R.

**$\beta$ -Amyrin from Manilla Elemi Resin.** II. ALEXANDER ROLLETT and KLOTHILDE BRATKE (Monatsh., 1923, 43, 685—686, cf. this vol., i, 476).—Potassium persulphate converts  $\beta$ -amyrin in acetic acid solution, in presence of sulphuric acid, into  $\beta$ -amyrin acetate, leaflets, m. p. 291—292°, soluble in concentrated sulphuric acid to give a yellow solution with a reddish-violet fluorescence. The acetate, on hydrolysis with methyl-alcoholic sodium hydroxide, gives *oxy*- $\beta$ -amyrin,  $\text{C}_{30}\text{H}_{47}\text{O}\cdot\text{OH}$ , prisms, m. p. 20

$\alpha$ - and  $\beta$ -forms which are presumably more stable than the corresponding forms of glucose. Sinigrin has been obtained in an anhydrous form,  $C_{10}H_{16}O_9NS_2K$ , compact, white, glistening needles, m. p.  $79^\circ$ ,  $[\alpha]_D -16.13^\circ$  (in water). This indicates that the decomposition of sinigrin by the enzyme myrosin is a simple hydrolysis,  $C_{10}H_{16}O_9NS_2K + H_2O = C_3H_5 \cdot NCS + C_6H_{12}O_6 + KHSO_4$ . W. O. K.

**Some Additive Compounds of Digitonin.** A. WINDAUS and R. WEINHOLD (*Z. physiol. Chem.*, 1923, 126, 299—307).—The following additive compounds of digitonin with alcohols and phenols are described.  *$\alpha$ -Naphtholdigitonin*,

$C_{55}H_{90}O_{29} \cdot C_{10}H_8O \cdot 8H_2O$ , very fine needles.  *$\beta$ -Naphtholdigitonin*,  $C_{55}H_{90}O_{29} \cdot C_{10}H_8O \cdot 10H_2O$ . *p-Bromophenoldigitonin*,  $C_{55}H_{90}O_{29} \cdot C_6H_5OBr \cdot 8H_2O$ , fine needles. *Phenyl mercaptan-digitonin*,  $C_{55}H_{90}O_{29} \cdot C_6H_5S \cdot 6H_2O$ . *Carvomentholdigitonin*,  $C_{55}H_{90}O_{29} \cdot C_{10}H_{20}O \cdot 10H_2O$ , fine needles. *1- $\alpha$ -Terpinolol-digitonin*,  $C_{55}H_{90}O_{29} \cdot C_{10}H_{18}O \cdot 6H_2O$ , very fine needles. *d- $\alpha$ -Terpineol-digitonin*,  $C_{55}H_{90}O_{29} \cdot C_{10}H_{18}O \cdot 8H_2O$ . *ac-Tetrahydro- $\beta$ -naphthol-digitonin*,  $C_{55}H_{90}O_{29} \cdot C_{10}H_{12}O \cdot 8H_2O$ , fine needles. *Phenylmethylcarbinol-digitonin*. *sec-Octylalcohol-digitonin*. These compounds are decomposed, by distillation either in a vacuum, or in steam.

W. O. K.

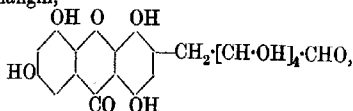

**Betulin.** K. ALB. VESTERBERG (*Ber.*, 1923, 56, [B], 845; cf. Vesterberg, A., 1922, i, 825; Schulze and Pieroh, A., 1922, i, 1045; Dischendorfer, this vol., i, 123).—Elementary analysis and, in particular, determination of the saponification number of crystalline betulin diacetate, m. p.  $218-218.5^\circ$ , lead the author to regard the presence of 30 carbon atoms in the betulin molecule as definitely established. In the formula,  $C_{30}H_{48}(OH)_2$ , which has also been proposed by Dischendorfer, the uncertainty with regard to the number of hydrogen atoms does not exceed two. H. W.

**Betulin. III.** IVAN KONSTANTINOVITSCH TRAUBENBERG (*J. Russ. Phys. Chem. Soc.*, 1917, 49, 381—394; cf. A., 1912, i, 260, 972).—*Betulin dibutyrate*,  $C_{34}H_{58}O_8(C_4H_7O)_2$ , m. p.  $107^\circ$ , has been prepared, thus establishing the hydroxylic nature of the two oxygen atoms of betulin. Betulin, on oxidation with potassium permanganate in acetic acid solution, gives *oxybetulin*,  $C_{28}H_{46}O_3$ , m. p.  $205-206^\circ$ , which yields an *acetate*, m. p.  $181-182^\circ$ ; the latter derivative being also obtained by the oxidation of betulin diacetate. Oxybetulin, on oxidation, gives *dehydrodioxybetulin*,  $C_{28}H_{38}O_4$ , m. p.  $256^\circ$ , which on further oxidation gives a substance not melting below  $310^\circ$ , and containing inorganic matter. As final products of oxidation were obtained *betulinic acid*,  $C_{14}H_{22}O_3$ , m. p.  $277^\circ$ , and a *lactone*,  $C_{15}H_{22}O_3$ , m. p.  $303^\circ$ . Betulinamic acid,  $C_{28}H_{38}O_{10}N_2$ , is shown to contain one nitro- and one nitrile group. From the above and preceding articles, it is concluded that betulin is a substance of the sterol type, and contains one primary and one secondary hydroxyl group, four saturated rings, and one double linking, situated on the chain joining the rings. One of the hydroxyl groups must be in the  $\beta$ - or  $\gamma$ -position to this double linking.

R. T.

**The Parent Substance of Indian Yellow.** WILHELM WIEHORSKI (*Arch. exp. Path. Pharm.*, 1923, 97, 462—488).—If mangin, which has been extracted from mango leaves, is fed to rabbits, euxanthic acid (Indian yellow) is excreted in the urine. It thus appears that mangin is the parent substance of Indian yellow.

*Mangin*,  $C_{19}H_{18}O_{11}$ , m. p.  $273^{\circ}$ ,  $[\alpha]_D -46^{\circ}$  in alcohol, is only slightly soluble in the usual neutral organic solvents. It crystallises from alcoholic solution in needles, from water in prisms. It is not hydrolysed by emulsin, invertase, or other ferments, and it forms an *octa-acetyl* derivative, an *octabenzoyl* derivative, and a lead salt,  $C_{19}H_{14}O_{11}Pb_2$ . When heated for a long time with hydrochloric acid, it yields lævulinic acid and tetrahydroxyxanthone, which was isolated as the lead salt. The following formula is assigned to mangin,

the position of the hydroxy-groups being uncertain.

Euxanthic acid,  $C_{19}H_{18}O_{11}$ , has the following constants: m. p.  $156\text{--}158^{\circ}$  (decomp.),  $[\alpha]_D -79\cdot43^{\circ}$ ,  $-81\cdot45^{\circ}$  in alcohol.

W. O. K.

**Preparation of Melanin from Benzene.** OSCAR ADLER (*Biochem. Z.*, 1923, 137, 201—205).—By treatment of benzene with successive portions of 3% hydrogen peroxide in presence of 1% aqueous ferric chloride solution, a 2.7% yield of *benzenemelanin* acid is formed, soluble in dilute alkalis and alcohols. When heated at  $270^{\circ}$  it is converted into *benzenemelanin*, a black, amorphous powder insoluble in alkalis or organic solvents.

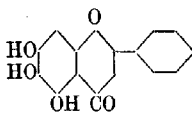

H. K.

**Synthesis of Dicyanine-A.** S. PALKIN (*Ind. Eng. Chem.*, 1923, 15, 379—381).—The conditions affecting the synthesis of dicyanine-A from 6-ethoxy-2:4-dimethylquinoline ethiodide were studied and variations tried in the kind of solvent used, concentration of hydroxyl-ion, type of alkali, catalysts, water, oxygen, time, and temperature. No solvent was found superior to ethyl alcohol, but excellent results were obtained with sodium sulphide; the alkali salt in 95% alcohol. Chloroform acts as a catalyst in the presence of sodium ethoxide, the yield of dye obtained being about twelve times that obtained by Mikeska, Haller, and Adams. The optimum conditions were, 1.5 c.c. of chloroform per 1 g. of intermediate, 25 g. of sodium sulphide ( $Na_2S_9H_2O$ ) in 100 c.c. of 95% alcohol, 1 g. of intermediate to 25 c.c. of alcohol and a temperature of  $50^{\circ}$  for thirty minutes. The dye produced was studied by the Bureau of Standards and found to be an efficient sensitiser.

H. C. R.

**Baicalin, a New Flavone-Glycuronic Acid Compound from the Roots of *Scutellaria baicalensis*.** KEITA SHIBATA, SHÔJIRO YATA, and MAKOTO NAKAMURA (*Acta Phytochim.*, 1923, 1, 105—109).—The name scutellarin was applied by Takahashi to a crystalline compound from *Scutellaria baicalensis*, to which he ascribed

the formula  $C_{10}H_8O_3$  (A., 1890, 64). The same name has, however, been accepted for a flavone-glycuronic acid compound found by Molisch and Goldschmiedt (A., 1902, i, 48) in other species of *Scutellaria*, and it is proposed to call Takahashi's compound *wogonin* (from "wogon," the Japanese term for the root). A new compound, *baicalin*, closely allied to scutellarin, occurs in the roots of *S. baicalensis*, and can be extracted from the roots by boiling 50% alcohol, the yield being 12.5% of the weight of dry root. It is a bright yellow, crystalline substance,  $C_{21}H_{18}O_{11}$ , m. p. 223°. When hydrolysed with concentrated sulphuric acid, it is decomposed into glycuronic acid and a flavone derivative, *baicalein*,  $C_{15}H_{10}O_5$ , yellow prisms, m. p. 264–265° (decomp.). A great deal of evidence indicates that baicalein is a trihydroxyflavone, an hydroxychrysin with all three hydroxy-groups in the one phenyl ring. By alkaline hydrolysis, baicalin gives acetophenone, and when fused with potassium hydroxide both baicalin and baicalein give benzoic acid. Baicalein appears to be identical with the 5:6:7-trihydroxy-

flavone (annexed formula) prepared synthetically by Bargellini (A., 1919, i, 545). Evidence that condensation with glycuronic acid to form baicalin takes place at the 6-hydroxy-group is furnished by the observation that baicalin is not oxidised by chloropentamminecobaltchloride, which gives a strong colour reaction with *o*-dihydroxy-compounds but not with corresponding meta-compounds. Scutellarin likewise fails to give a reaction with this reagent, and must therefore be constituted similarly to baicalin.

*Pentabenzoylscutellarin* forms a white, microcrystalline powder, m. p. 237–238° (decomp.).

Baicalin gives with ferric chloride in alcoholic solution a dark green colour, and with lead acetate an orange-red precipitate. It dissolves in alkalis with a yellow colour, and reduces ammoniacal silver nitrate in the cold. It is difficult to alkylate, but forms with diazomethane in acetone solution a *monomethyl* derivative, m. p. 211–212° (decomp.); this contains a free carboxy-group. *Dibromobaicalin* softens above 270°. Baicalin is levorotatory,  $[\alpha]_D^{25} -144.9^\circ$ . *Tetracetylbaicalin* forms microscopic prisms containing  $1H_2O$ , m. p. 256–257°. The fact that only a tetra-acetyl derivative is formed indicates that the glycuronic acid is in the lactone form. A small quantity of what appeared to be a *penta-acetylbaicalin*, m. p. 212–213° (decomp.), was also obtained. *Tetrabenzoylbaicalin* forms a grey, microcrystalline powder, m. p. 229–230°.

*Tribenzoylbaicalein* forms small prisms, m. p. 199.5°. Triacetylbaicalein agrees in properties with Bargellini's triacetyl derivative of 5:6:7-trihydroxyflavone (*loc. cit.*). Free baicalein is present with baicalin in the roots of the plant.

Further investigation of wogonin shows that the substance as analysed by Takahashi contained water of crystallisation. The correct formula is  $C_{18}H_{12}O_4$ , and it contains a methoxy-group. *Acetylwogonin*,  $C_{18}H_{14}O_6$ , forms long, white needles, m. p. 152–

53°; *benzoylwogonin* forms yellowish-white needles, m. p. 170°; *methylylwogonin*,  $C_{16}H_{11}O_3 \cdot OMe, H_2O$ , forms yellowish-white needles, m. p. 180—181°.

Baicalein and scutellarein, like other hydroxyflavones (cf. this vol., ii, 360) show two absorption bands in the ultra-violet, the bands showing shifts such as would be expected from the constitutions of the compounds. In baicalin, the first band disappears, only a broad band at 3500 remaining, but in scutellarin both bands persist, perhaps through the influence of the 4'-hydroxy-group. Wogonin has an unusual spectrum with only one band, at 3500, but acetylwogonin, like triacetylbaicalein, shows the true flavone spectrum.

The green parts of *S. baicalensis* are found to contain scutellarin. The relation between the scutellarin of the leaves and the baicalin of the roots is a question of great biochemical interest.

E. H. R.

**The Extractive Substances of Muscle. Carnosine and its derivatives.** IVAN A. SMORODINCEV (*J. Russ. Physiol.*, 1919, 2, 98).—The author reviews the literature of the subject and describes the following new salts of the dipeptide: *Sulphate*, m. p. 238—40°; *orthophosphate*, m. p. 205—207°; *metaphosphate*, m. p. 200—203°; *iodate*, m. p. 188—190°; *oxalate*, m. p. 216—218°; *nitrate*, m. p. 195—200°; *phosphotungstate*,

The *phenylcarbamido*-derivative, m. p. 178—180°, has also been prepared. Carnosine is hydrolysed by erepsin.

E. S.

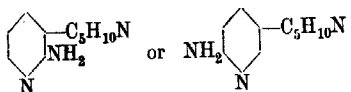

**The Alkaloids of *Corydalis cava*.** ERNST SPÄTH, ERICH LOSETTIG, and OTTMAR TRÖTHANDL (*Ber.*, 1923, 56, [B], 875—79).—During the course of preparation of corydaline from *Corydalis cava*, two new alkaloids, *d*-tetrahydropalmatine and *d*-corypalmine, have been isolated; in the latter, one of the four methoxy-groups of tetrahydropalmatine is replaced by hydroxyl.

The alkaloids from *Corydalis cava* are dissolved in ether and agitated with sodium hydroxide solution to remove phenolic substances. The fully alkylated compounds are dissolved in hydrochloric acid and, from this solution, *d*-tetrahydropalmatine hydrochloride separates in the course of a few days. *d*-Tetrahydropalmatine,  $C_{21}H_{25}O_4N$ , forms colourless crystals which exhibit distinct triboluminescence when crushed. It has m. p. 142°,  $d^{20}_D + 292.5^\circ$  in alcoholic solution. The constitution of the alkaloid is established by its dehydrogenation with iodine and ethyl alcohol and treatment of the product with magnesium methyl iodide which yields a compound identical with that obtained previously by Späth and Lang (*A.*, 1922, i, 166) from palmatine and magnesium methyl iodide. The conception that the dehydro-compound is palmatine is confirmed by direct comparison of the maternal iodides and of the corresponding tetrahydro-derivatives.

The bulk of the bulbocapnine is removed from the phenolic alkaloids; fractional extraction of the solution of the remainder in chloroform with very dilute hydrochloric acid gives corybulbine

and corypalmine. The former has been considered by Dobbin, Lander, and Paliatsens (T., 1901, 79, 89) as corydaline in which one methoxy-group has suffered demethylation. This conception is confirmed by its conversion into dehydrocorybulbine, methylation of the latter, and reduction to the tetrahydro-compound, which is found to be identical with *r*-corydaline, m. p. 135°. The latter is also obtained by the methylation of corybulbine with diazomethane. *Corypalmine* forms small, colourless crystals, m. p. 236–237°,  $[\alpha]_D^{25} +280^\circ$  when dissolved in chloroform; it gives *d*-tetrahydropalmatine when methylated. H. W.

**2-(or 6-)Aminonicotine.** A. E. TSCHITSCHIBABIN and L. A. BUCHHOLZ (J. Russ. Phys. Chem. Soc., 1920, 50, 548–552).—The action of sodamide on nicotine in the presence of an indifferent solvent such as vaseline or toluene leads to the formation of an amino-derivative in a manner similar to that observed with other derivatives of pyridine (see A., 1915, 1, 590). The new substance

may be the 2- or the 6-amino-compound (annexed formulæ) and is obtained in a yield of about 10%. After crystallisation from

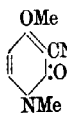

light petroleum it melts at 124–125° and forms biaxial leaflets or plates, probably of the monoclinic system; the *dipicrate* forms long, thin yellow needles, m. p. 223–225°; the *chloroplatinate*, red prisms, contains 2H<sub>2</sub>O, m. p. 244–245°. The action of nitrous acid in the presence of sulphuric acid on aminonicotine leads to 2-(or 6-)*hydroxynicotine*, crystals, m. p. 121–123°; the *dipicrate* forms large, lustrous needles, m. p. 196–198°, and the *chloroplatinate*, small orange crystals, m. p. 246–248°, also occurring in the form of red prisms containing 3H<sub>2</sub>O. G. A. R. K.

**The Morphine Group. I. A Discussion of the Constitutional Problem.** JOHN MASSON GULLAND and ROBERT ROBINSON (T., 1923, 123, 980–998).

**The Morphine Group. II. Thebainone, Thebainol, and Dihydrothebainone.** JOHN MASSON GULLAND and ROBERT ROBINSON (T., 1923, 123, 998–1011).

**Yohimbine (Quebrachine). II. apo-Yohimbine and Deoxy-yohimbine.** GEORGE BARGER and ELLEN FIELD (T. 1923, 123, 1038–1043).

**The Constitution of Ricinine.** ERNST SPÄTH and GROS KOLLER (Ber., 1923, 56, [B], 880–887).—The authors have succeeded in replacing the methoxy-group of ricinine by hydrogen and thereby obtaining a substance which they designate ricinidine. The compound is shown by direct synthesis to be 3-cyano-1-methyl-2-pyridone, so that ricinine must be regarded as 3-cyano-4-methoxy-1-methyl-2-pyridone (annexed formula). The constitution assigned tentatively to ricinine (Späth and Tschelnitz, A., 1922, i, 571) is therefore withdrawn.

Ricinine is converted by potassium hydroxide into ricinic acid (f. Böttcher, A., 1918, i, 304), which is transformed by phosphoryl chloride at  $100^\circ$  into 4-chloro-3-cyano-1-methyl-2-pyridone,  $\text{H}_5\text{ON}_2\text{Cl}$ , m. p.  $159^\circ$ ; the latter is reconverted by a solution of dium in methyl alcohol into a mixture of ricinic acid and ricinine. Hydrogenation of the chloro-compound in the presence of palladised iridium sulphate leads to the production of ricinidine [3-cyano-1-methyl-2-pyridone], b. p.  $243^\circ/18$  mm., m. p.  $140^\circ$ . The latter is hydrolysed successively to the corresponding amide, m. p.  $216^\circ$ , and to the carboxylic acid,  $\text{C}_7\text{H}_7\text{O}_3\text{N}$ , colourless needles, m. p.  $184^\circ$ . The elucidation of the constitution of ricinine depends on the cognition of this acid as 1-methyl-2-pyridone-3-carboxylic acid. For this purpose, the three possible acids, viz. 2-pyridone-1-acetic acid, and 1-methyl-2-pyridone-3- and -6-carboxylic acids, have been synthesised.

2-Pyridone-1-acetic acid,  $\text{CH} \begin{smallmatrix} \text{CH}\cdot\text{CO} \\ \text{CH}\cdot\text{CH} \end{smallmatrix} \text{N}\cdot\text{CH}_2\cdot\text{CO}_2\text{H}$ , m. p.  $220^\circ$ —

$23^\circ$ , is obtained from 2-methoxypyridine and methyl iodoacetate. Methyl-2-pyridone-6-carboxylic acid is prepared with difficulty by the action of methyl iodide on the di-silver salt of 2-hydroxypyridine-6-carboxylic acid; it has m. p.  $247$ — $248^\circ$ . Similar treatment of the di-silver salt of 2-hydroxypyridine-3-carboxylic acid and subsequent hydrolysis of the product leads to the isolation of methyl-2-pyridone-3-carboxylic acid, m. p.  $184^\circ$ , which is identical with the acid obtained from ricinidine; in this instance, also, ethylation is a matter of difficulty, and is more conveniently effected by treating the dry di-sodium salt with methyl iodide. Methyl-2-pyridone-3-carboxylic acid is converted by successive treatment with thionyl chloride and ammonia into the amide, m. p.  $216$ — $217.5^\circ$  [identical with that obtained during the hydrolysis of ricinidine (see above)], which is further transformed by thionyl chloride or phosphoryl chloride into ricinidine.

Further proof of the identity of ricinidine with 3-cyano-1-methylpyridone is deduced from the observation that it is converted by phosphoryl chloride and phosphorus pentachloride at  $150^\circ$  into 4-chloro-3-cyanopyridine, m. p.  $103$ — $105^\circ$ . The synthesis of the latter substance is effected by the successive action of phosphoryl chloride and phosphorus pentachloride and ammonia on 2-hydroxypyridine-3-carboxylic acid whereby 2-hydroxypyridine-3-carboxylide, m. p.  $163$ — $164^\circ$ , is obtained which is transformed by phosphoric oxide into 2-chloro-3-cyanopyridine. H. W.

#### The Nitration of 2-Aminopyridine. A. E. TSCHITSCHIBABIN

and I. G. BYLINKIN (*J. Russ. Phys. Chem. Soc.*, 1920, 50, 471—474; cf. A., 1922, i, 573).—It has already been shown (cf. A., 1916, 24; 1915, i, 591) that the nitration of 2-aminopyridine leads to the formation of two isomeric nitro-derivatives, the main product being 5-nitro-2-aminopyridine, and the other is now shown to be 3:2-compound. The formation of the latter is favoured by raising the temperature during the isomerisation of the nitroamine from the nitro-compound (cf. above).

When diazotised in the presence of sulphuric acid, the 3:2-compound (m. p. 162°) yields 3-nitro-2-hydroxypyridine, yellow needles, from hot water, m. p. 224°, readily soluble in dilute alkali hydroxides. Diazotisation in hydrochloric acid solution leads to 2-chloro-3-nitropyridine, flattened needles, m. p. 101–102°, insoluble in alkali hydroxides, but feebly basic. All attempts to reduce the 3:2-compound to the corresponding diamine failed.

2-Chloro-5-nitropyridine obtained by the diazotisation of the 5:2-isomeride (cf. A., 1915, i, 591) yields, on reduction with stannous chloride, the corresponding amino-compound identical with that prepared by Mills and Widdows (T., 1908, 93, 1372), m. p. 81–82°. The replacement of the amino-group in this compound by bromine by the Sandmeyer reaction leads to 2-chloro-5-bromopyridine, white plates, m. p. 71°, possessing a strong and characteristic odour. The amino-group in the compound, m. p. 81–82°, like that of 3-aminopyridine, is readily diazotisable, and the diazonium compounds prepared in hydrochloric acid solution couple with  $\alpha$ - and  $\beta$ -naphthol in alkaline solution, giving red substantive cotton dyes which gradually change to brownish-red and orange, respectively; only the latter is fairly stable to acids.

5-Nitro-2-hydroxypyridine (cf. A., 1915, i, 591) is converted through the silver salt into 5-nitro-2-ethoxypyridine, white plates, m. p. 72°. The reduction of this compound with stannous chloride gives a very unstable, oily amine, which is converted by acetic anhydride into 5-acetamido-2-ethoxypyridine, flattened needles, m. p. 122°. G. A. R. K.

**The Bromination of 2-Aminopyridine.** A. E. TSCHITSCHIBABIN and (MLLE) V. S. TIASHELOVA (*J. Russ. Phys. Chem. Soc.* 1920, 50, 483–492).—The nuclear hydrogen atoms of 2-aminopyridine, unlike those of pyridine itself, appear to be readily substituted (cf. A., 1915, i, 591; 1916, i, 224) and bromination proceeds easily, best of all in the presence of one molecular proportion of sulphuric acid. The products are 5-bromo-2-aminopyridine, flattened prisms, m. p. 137° (*picrate*, yellow needles, m. p. 257°), and 3:5-dibromo-2-aminopyridine, white needles, m. p. 105°. The two compounds are separated by means of light petroleum in which the monobromo-compound is sparingly soluble. The dibromo-compound is identical with that described by Fischer and Chur (A., 1916, i, 741) and gives on treatment with nitrous acid the corresponding dibromohydroxy-compound, m. p. 207–208°, previously prepared by Koenigs and Geigy (A., 1884, 1186, 1368).

Diazotisation of the monobromo-compound in the presence of sulphuric acid (cf. preceding abstract) leads to 5-bromo-2-hydroxypyridine, large, sparkling prisms, m. p. 177–178°. Diazotisation in hydrochloric acid solution gives 2-chloro-5-bromopyridine, colourless scales, m. p. 71°, with an odour reminiscent of dibromobenzene volatile in steam, identical with the substance obtained by Tschitschibabin and Bylinkin (preceding abstract). On treatment with sodamide and amyl nitrite (Tschitschibabin and Riasancev, A.

1916, i, 224) an unstable substance is obtained which shows the reactions of an isodiazoxide, giving a red dye with  $\beta$ -naphthol and yielding with hydrochloric acid the chlorobromo-compound mentioned above and with hydrobromic acid 2:5-dibromopyridine, flattened needles, m. p. 94–95°, which sublimes. Nitration of the monobromo-compound dissolved in concentrated sulphuric acid leads to the nitroamine, microscopic needles, m. p. 181° (decomp.), which when heated with sulphuric acid isomerises to 5-bromo-3-nitro-2-aminopyridine, large yellow needles from alcohol, or short needles or prisms from benzene, m. p. 205°.

G. A. R. K.

**The Bromination of Nitro-2-aminopyridines.** A. E. TSCHITSCHIBABIN (*J. Russ. Phys. Chem. Soc.*, 1920, 50, 492–494).—It has been shown (preceding abstract) that the bromination of 2-aminopyridine leads to 3- and 5-bromo-compounds. The two nitroaminopyridines should therefore yield two different monobromo-derivatives, one of which should be identical with the nitration product of 5-bromo-2-aminopyridine. This is found to be the case. 5-Nitro-2-aminopyridine, m. p. 188° (cf. A., 1915, i, 591), gives on bromination in the presence of dilute sulphuric acid (20 per cent.) a good yield of 3-bromo-5-nitro-2-aminopyridine, yellow needles, m. p. about 215° (decomp.); the compound is slowly decomposed by light. 3-Nitro-2-aminopyridine, m. p. 162°, gives, when brominated under similar conditions, 5-bromo-3-nitro-2-aminopyridine, m. p. 205°, identical with that obtained by Tschitschibabin and Tiashelova (preceding abstract), thus confirming the constitution previously assigned to the compound melting at 162°.

G. A. R. K.

**The Sulphonation of 2-Aminopyridine.** A. E. TSCHITSCHIBABIN and (MILLE) L. S. TIASHELOVA (*J. Russ. Phys. Chem. Soc.*, 1920, 50, 495–497).—Whilst pyridine is sulphonated with considerable difficulty, 2-aminopyridine undergoes sulphonation almost as readily as aniline. When it is heated with fuming sulphuric acid (10%  $\text{SO}_3$ ) at 180° for four to five hours, a sulphonic acid, nodular aggregates of white crystals, m. p. 326–327° (decomp.), is produced. The salts of this acid with metals of the alkali group are very soluble in water, those of calcium, strontium, and barium less so. The sulphonic acid dissolves with difficulty in dilute acids. The orientation of the sulphonic acid is not yet certain, but it is probably the 2:5-aminosulphonic acid. On treatment with nitrous acid, it passes into the corresponding 2-hydroxysulphonic acid which is isolated in the form of its hydrated sodium salt,  $\text{HC}_5\text{H}_3\text{SO}_2\text{Na} \cdot 1\frac{1}{2}\text{H}_2\text{O}$ , which loses its water of crystallisation at 25°. Aqueous solutions of the salt give crystalline precipitates with barium and calcium chlorides.

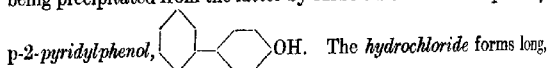

G. A. R. K.

**The Phenylation of 2-Aminopyridine by Ullmann's Method.** A. E. TSCHITSCHIBABIN (*J. Russ. Phys. Chem. Soc.*, 1920, 50, 497–502).—2-Aminopyridine readily reacts with bromo- or iodo-benzene in the presence of potassium carbonate and metallic copper, the

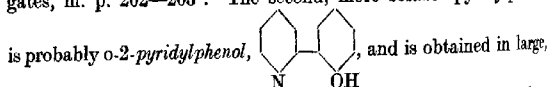

y\*

reaction product being separated into the constituents by distillation at atmospheric pressure. The fraction up to  $240^{\circ}$  contains unchanged starting material, whilst the oil boiling between  $240^{\circ}$  and  $345^{\circ}$  consists mainly of 2-anilinopyridine, m. p.  $108^{\circ}$  (Fischer, A., 1903, i, 52; 1899, i, 635), short, thick prisms; the *picrate* forms prisms, m. p.  $222^{\circ}$ . 2-Diphenylaminopyridine constitutes the highest fraction, b. p.  $345\text{--}370^{\circ}$ , and forms plates, m. p.  $104^{\circ}$ . The *picrate*, prepared in alcoholic solution, melts at  $174^{\circ}$ , and forms plates or long needles; it is more soluble in alcohol and acetone than 2-anilinopyridine *picrate*.  
G. A. R. K.

**The Diazotisation and Diazo-reactions of 2-Aminopyridine.**  
A. E. TSCHITSCHIBABIN (*J. Russ. Phys. Chem. Soc.*, 1920, 50, 502—511).—Attempts made to introduce the pyridine nucleus into organic compounds by the Grignard reaction on 2-bromo- and 2-iodo-pyridine failed; the preparation of these substances from sodium 2-pyridineisodiazoxide (A., 1916, i, 224) has been improved and is described. Successful results are, however, obtained by the interaction of the latter substance with phenol. After removing phenol, etc., three substances are obtained, one of which may be readily separated owing to its insolubility in alkali hydroxides. This consists of 2-phenoxypyridine, b. p.  $277\text{--}277.5^{\circ}$ , m. p.  $46\text{--}48^{\circ}$ , possessing an odour reminiscent of diphenyl ether, the orange *chloroplatinate*, small prisms, m. p.  $175\text{--}177^{\circ}$ , and the *picrate* were also prepared. The two compounds soluble in alkali are isomeric pyridylphenols, and may be separated by crystallisation from benzene. The less soluble compound separates in white leaflets or thick, lustrous, hexagonal plates containing a molecule of benzene of crystallisation; after removing the latter it melts at  $159\text{--}160^{\circ}$  and is readily soluble both in dilute acids and alkalis, being precipitated from the latter by carbon dioxide. It is probably

slender needles, m. p.  $215\text{--}218^{\circ}$ ; the *chloroplatinate*, large, orange-yellow, flattened needles, m. p.  $210\text{--}211.5^{\circ}$  (decomp.), whilst the sparingly soluble *picrate* is obtained in nodular, crystalline aggregates, m. p.  $202\text{--}203^{\circ}$ . The second, more soluble pyridylphenol

greenish-yellow prisms, m. p.  $56^{\circ}$ ; it is less soluble in alcohol than the preceding compound and its phenolic properties are less marked; the yellow colour may perhaps be due to a quinonoid structure. The *hydrochloride* is obtained in a hydrated form, colourless prisms, m. p.  $56^{\circ}$ , which lose water in a desiccator, the anhydrous substance melting at  $167\text{--}170^{\circ}$ . The *chloroplatinate*, microscopic needles, softens at  $227\text{--}228^{\circ}$ . The *picrate* forms slender, long, yellow needles, m. p.  $174^{\circ}$ .  
G. A. R. K.

**Di-2-pyridylamine.** A. E. TSCHITSCHIBABIN and M. A. VOROBYEV (*J. Russ. Phys. Chem. Soc.*, 1920, **50**, 519—522).—Di-2-pyridylamine was originally obtained by Tschitschibabin and Zeide (A., 1915, i, 590), and also by Steinhäuser and Diepolder (A., 1916, **739**), by heating 2-chloropyridine with 2-aminopyridine in the presence of zinc chloride or barium oxide. It is now shown that the best method of preparing this substance consists in heating 2-aminopyridine with its hydrochloride; a yield of 40% of the theoretical is obtained if the reaction mixture is heated in sealed tubes at 240—250° for twenty to thirty hours. The *hydrochloride* of 2-aminopyridine is prepared by the usual methods, and is obtained in the form of an extremely deliquescent solid, melting at about 16°, and, after drying in a desiccator, containing 2H<sub>2</sub>O, which it loses at 105°. Di-2-pyridylamine forms slender, colourless needles, m. p. 95°. The specimen previously described (cf. above) melted at 84°, but on cooling solidified and melted at 95°; the substance thus appears to be polymorphous. The *hydrochloride* forms lustrous prisms, m. p. 115—116°, containing 3H<sub>2</sub>O (cf. however, A., 1916, **739**), which are slowly lost on drying. The *picrate* of the base forms needles, m. p. 225°. The *sulphate* forms hair-like needles, m. p. 248°.

G. A. R. K.

**The Investigation of 2:6-Diaminopyridine.** A. E. TSCHITSCHIBABIN and O. A. ZEIDE (*J. Russ. Phys. Chem. Soc.*, 1920, **50**, 522—533).—2:6-Diaminopyridine, prepared as before (A., 1915, i, 590), is shown to be a mono-acid base; like 2:6-dihydroxypyridine (Gattermann and Skita, A., 1916, i, 419), it couples with aromatic diazo-compounds. The action of nitrous acid on the diamine does not lead to the formation of a colouring matter corresponding with Bismarck brown, but to a 3-nitroso-compound.

The *hydrochloride* of the base is obtained in the form of very unstable white needles. The *sulphate*, (C<sub>5</sub>H<sub>4</sub>N<sub>2</sub>)<sub>2</sub>·H<sub>2</sub>SO<sub>4</sub>·H<sub>2</sub>O, forms yellow prisms. The *picrate* forms long, dark-yellow needles, m. p. 240°.

A *monoacetyl* derivative could not be obtained; the *diacetyl* compound, readily formed by the action of acetic anhydride on the base in benzene or glacial acetic acid, forms white, lustrous plates, m. p. 203°. The direct nitration of 2:6-diaminopyridine gives a very poor yield of the nitro-derivative, but the diacetyl compound is readily nitrated in the presence of concentrated sulphuric acid, giving a 70% yield of 3-nitro-2:6-diacetamidopyridine, light yellow needles, m. p. 192—193°; it appears to form salts with hydrochloric and sulphuric acids. The compound is readily deacetylated by hydrochloric acid, giving 3-nitro-2:6-diaminopyridine, lustrous yellow plates, m. p. 230° (blackens). The action of nitrous acid on 2:6-diaminopyridine under a variety of conditions, but best of all in the presence of acetic acid, leads to 3-nitroso-2:6-diaminopyridine, which crystallises in lustrous, ruby-red needles; it blackens and decomposes without melting when heated; it forms yellow salts with acids, and does not give Liebermann's nitroso-reaction. The mother-liquors from the preparation of this compound readily assume a green or blue coloration, probably due to the presence of readily oxidisable

hydroxypyridines. The nitroso-compound, on oxidation with hydrogen peroxide in ammoniacal solution, yields the nitro-compound described above. The reduction of the nitroso-compound with sodium hyposulphite or zinc dust does not lead to the desired triaminopyridine, owing to the extreme readiness with which the reduction product is oxidised to black colouring matters.

Benzenediazonium chloride couples with 2:6-diaminopyridine, yielding the compound  $C_{11}H_{11}N_5$ , orange-yellow needles, m. p.  $137^\circ$ , soluble in water with an orange colour, and in sulphuric or hydrochloric acid with a red colour. The solution in hydrochloric acid is decolorised by zinc dust, but rapidly assumes a green colour when exposed to the air.

With diazotised benzidine, a red compound,  $C_{22}H_{10}N_{10}$ , is produced which crystallises in lustrous, bronze-coloured plates and yields bluish-black, sparingly soluble salts with acids; it dissolves in sulphuric acid with an intense blue colour. G. A. R. K.

**6-Amino-2-methylpyridine.** O. A. ZEIDE (*J. Russ. Phys. Chem. Soc.*, 1920, **50**, 534—543).—The preparation of 6-amino-2-methylpyridine, first obtained by Tschitschibabin and Zeide (*A.*, 1915, i, 590) has been improved in details and is described. The compound is a mono-acid base the reactions of which are shown to be analogous to those of 2-aminopyridine (compare preceding abstracts). The pure base is a snow-white, crystalline mass, m. p.  $40^\circ$ , which is deliquescent. The following salts were prepared: the *hydrochloride* forms white needles; the *hydrobromide*, long, white prisms, m. p.  $149$ — $150^\circ$ ; the *hydriodide*, yellow prisms, m. p.  $162^\circ$ ; the *sulphate*, hard, colourless prisms; the *nitrate*, white needles, m. p.  $168^\circ$ ; the *picrate*, small, yellow needles, m. p.  $202^\circ$ ; *chloroplatinate*, flat, orange, rhombic prisms, m. p.  $209^\circ$ .

The *acetyl* compound, prepared by means of acetic anhydride in benzene solution, forms elongated, white prisms, m. p.  $90^\circ$ , readily soluble in water, alcohol, ether, or chloroform, sparingly soluble in cold petroleum. The *benzoyl* compound, prepared by the Schotten-Baumann method, forms hard, colourless prisms, m. p.  $90^\circ$ , from a mixture of benzene and petroleum; it is sparingly soluble in water and petroleum, and readily soluble in alcohol, benzene, chloroform, or ether.

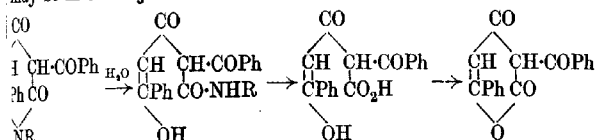

The action of nitrous acid on 6-amino-2-methylpyridine in hydrochloric acid solution leads to the formation, in 50% yield, of 6-chloro-2-methylpyridine, a colourless, mobile liquid with a sweet odour, readily miscible with organic solvents, b. p.  $183.5$ — $184^\circ/749$  mm. (*chloroplatinate*, red prisms insoluble in alcohol, blackens above  $208^\circ$ , decomposes above  $290^\circ$ ). 6-Hydroxy-2-methylaminopyridine is formed as a by-product in this reaction, and is separated from the chloro-compound owing to its solubility in alkalis; or it can be obtained by the action of nitrous acid on the amino-compound in the presence of sulphuric acid. It crystallises from a mixture of benzene and light petroleum in groups of needles, m. p.  $159^\circ$  (*picrate*, m. p.  $149.5$ — $150^\circ$ , light yellow needles from water, alcohol, or ethyl acetate; very soluble in acetone); the hydroxy-compound is identical with that prepared by Errera (*A.*, 1901, i, 43).

The nitration of the amine under the usual conditions leads to a 90% yield of 6-nitroamino-2-methylpyridine, slightly yellow needles from hot water or colourless crystals from alcohol, decomp. about 94°. The nitroamine is readily isomerised under the conditions previously employed (see preceding abstracts) to two isomeric nitro-compounds. The isomeride which is volatile in steam is assumed to be 5-nitro-6-amino-2-methylpyridine and forms delicate, light yellow needles, m. p. 141°. The isomeride which is not volatile in steam is taken to be 3-nitro-6-amino-2-methylpyridine; this compound is formed in greater amount than the 5-nitro-compound and is less soluble; it forms yellow leaflets, m. p. 188°. Both isomerides form colourless solutions in strong acids, and these solutions turn yellow on dilution; they are soluble in dilute alkalis but not in dilute acids. G. A. R. K.

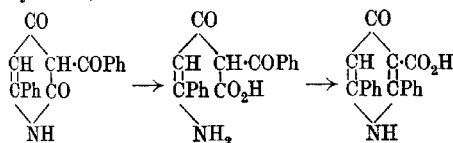

**The Lactam Derivatives of Dehydrobenzoylactic Acid.**  
P. PETRENKO-KRITSCHENKO (*J. Russ. Phys. Chem. Soc.*, 1917, 49, 251-259; cf. *ibid.*, 1915, 47, 645).—The reactions of some lactam derivatives of dehydrobenzoyl-acetic acid,

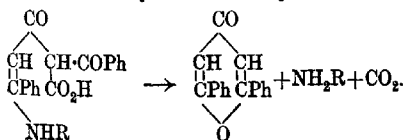

and its *N*-methyl derivative, with acids and strong and weak alkalis are explained as follows. With weak alkali both these substances are hydrolysed to an  $\alpha$ -pyrone derivative, as follows, where R may be H or CH<sub>3</sub>:

With strong alkalis, the free lactam forms 2:6-diphenylpyridone-3-carboxylic acid, as follows:

In the case of the *N*-methyl derivative, the methyl group is removed by hydrolysis, and the same product is then obtained as from the unsubstituted lactam. With strong acids, the reaction is as follows, where -R may be -H or -CH<sub>3</sub>:

R. T.

**The Methylation of Pyrrol Ketones.** B. V. TRONOV (*J. Russ. Phys. Chem. Soc.*, 1917, **49**, 272—282).—1-Methyl-2-pyrrole methyl ketone, b. p. 199—201°/739 mm.,  $d_4^{25}$  1.0445,  $n_D^{25}$  1.5403, is obtained in 56% yield by heating the sodium salt of 2-pyrrol methyl ketone with methyl iodide in a sealed tube, whereas Ciamician and Dennstedt (A., 1885, 378) obtained only an 18% yield by acting on 1-methylpyrrole with acetic anhydride. 1-Methyl-2-pyrrole phenyl ketone, b. p. 299—301°/747 mm.,  $d_4^{25}$  1.1312,  $n_D^{25}$  1.6225, is prepared in 70% yield by the action of dimethyl oxalate on the sodium salt of 2-pyrrole methyl ketone. *Di-1-methyl-2-pyrrol ketone*, b. p. 305—307°/755 mm.,  $d_4^{25}$  1.1444,  $n_D^{25}$  1.6347, is prepared in the same way in 65% yield. At the same time, some *di-2-methyl-5-pyrrol ketone*, m. p. 192—197°, is produced. Other methods tried for the preparation of the di-1-methylpyrrol ketone did not give the desired product. The action of magnesium methyl iodide on 1-methyl-2-pyrrol phenyl ketone yields  $\alpha$ -methylpyrrol- $\alpha$ -phenyl  $\Delta^2$ -allene,  $\text{CHMe} \cdot \text{CPh} \cdot \text{C}_4\text{H}_9\text{NMe}$ , b. p. 281—283°/750 mm.,  $d_4^{25}$  1.0228,  $n_D^{25}$  1.5967. R. T.

**Relation between Absorption and Structure.** V. The **N-Phenylpyridinium Salts.** V. A. IZMAILSKI (*J. Russ. Phys. Chem. Soc.*, 1918, **50**, 190—205; cf. König, A., 1906, i, 109; 1911, i, 485).—Various 1-phenylpyridinium salts are reinvestigated and described. These are as follows: 1-Phenylpyridinium bromide, yellow needles, m. p. 155°, iodide, red crystals, m. p. 207°, chloride ( $\text{H}_2\text{O}$ ), white needles, m. p. 104—105°, chlorate, white plates with blue fluorescence, m. p. 214°. *o*-Iodophenylpyridinium bromide, yellow crystals, m. p. above 260°, iodide, yellow plates, m. p. 253°, chlorate, white crystals, m. p. 162°. *p*-Iodophenylpyridinium chloride, colourless crystals, m. p. above 260°, chlorate, colourless crystals, m. p. 213°. *m*-Iodophenylpyridinium bromide, colourless crystals, m. p. 189°, iodide, yellow crystals, m. p. 196—197°, chlorate, white plates, m. p. 146°. Tribromo-*m*-iodophenylpyridinium bromide, white crystals, m. p. above 260°. 5-Iodo-*o*-tolylpyridinium bromide, yellow crystals, with 1 molecule of water, m. p. 137—140°, iodide, orange-brown prisms, m. p. above 260°. 2-Hydroxy-1-phenylpyridinium chloride, yellow crystals, m. p. 210°, iodide, yellow crystals, m. p. 162°, chlorate, white needles, m. p. 154°, bromide, white needles, m. p. 128°.  $\beta$ -Hydroxy-*p*-iodophenylpyridinium chloride, white crystals, m. p. 200°, acid sulphate, yellow leaves, m. p. 147°. 1-*o*-Anisylpyridinium bromide, white crystals, m. p. 150°, iodide, yellow crystals, m. p. 153°, chloride ( $\text{H}_2\text{O}$ ), yellow crystals, m. p. 137.5°, chlorate, white crystals, m. p. 132°, hydrogen sulphate ( $\text{H}_2\text{O}$ ), yellow needles, m. p. 168°. *p*-Anisylpyridinium bromide, yellow crystals containing 1 molecule of alcohol of crystallisation, m. p. 123.5°, iodide, yellow crystals, m. p. 160°, chloride, white crystals, m. p. 100°, chlorate, white plates, m. p. 154°. *m*-Methoxyphenylpyridinium iodide, yellow needles, m. p. 122—123°, chlorate, white, faintly fluorescent needles, m. p. 113—114°.  $\beta$ -Naphthylpyridinium bromide, needles, m. p. 189°, iodide, yellow crystals, m. p. 201°, chloride, white crystals,

containing 1 molecule of alcohol of crystallisation, m. p. 100—103°, chlorate, colourless leaves, m. p. 192—193°. *o*-Phenetidylpyridinium bromide, needles, m. p. 195—196°, iodide, yellow needles, m. p. 186°. R. T.

**Derivatives of Indole.** SAJURO KURODA (*J. Pharm. Soc. Japan*, 1923, 131—142).—Applying Fischer's method for the synthesis of indole to many phenylhydrazones of ketones, the author has isolated the corresponding indole derivatives; except the product from menthone, these give a red coloration to a paper shavings moistened with hydrochloric acid. The process in general consists in heating a mixture of equal quantities of the hydrazone and zinc chloride at a suitable temperature.

**3-Benzyl-2-methylindole** prepared from benzylacetonephenylhydrazone, m. p. 59°, and zinc chloride by heating on the water-bath, forms long plates, m. p. 116°. **2-Methyl-3-propylindole**, prepared from methyl-butyl-ketonephenylhydrazone and zinc chloride, is a light, brownish-red oil, b. p. 195°/40 mm. **2-Methyl-3-isopropylindole**, prepared from methylisobutyl-ketonephenylhydrazone and zinc chloride, is a light yellow, viscous oil, b. p. 173°/15 mm. **2-Methyl-3-n-octylindole**, prepared from methyl-nonyl-ketonephenylhydrazone and zinc chloride at 100°, is a yellow oil, b. p. 230—235°/35 mm. **3-Benzyl-1:2-dimethylindole**, prepared from benzylacetonephenylmethylhydrazone (a reddish-brown oil) and zinc chloride at 150°, is a light yellow, viscous oil, b. p. 235°/35 mm., having slight green fluorescence. **1:2-Dimethyl-3-propylindole**, prepared from methyl-butyl-ketonephenylmethylhydrazone and zinc chloride at 100°, is a light reddish-brown oil, b. p. 187°/35 mm. **1:2-Dimethyl-3-n-octylindole**, an oil, b. p. 25—230°/36 mm., was prepared from methyl-nonyl-ketonephenylmethylhydrazone, and zinc chloride at 100°. Camphorphenylhydrazone, prepared by Balbiano's method (*A.*, 1886, 72, 808), boils at 210°/17 mm., and yields a hydrochloride, m. p. 151°, when hydrogen chloride is passed into its ethereal solution, without formation of aniline and camphorenonitrile (cf. Balbiano, *loc. cit.*). Its bromine compound,  $C_{16}H_{22}N_2Br_2$ , forms white needles, m. p. 186°. **Camphorindole** forms colourless plates, m. p. 94°, b. p. 210—215°/25 mm., and is prepared by heating a mixture of the hydrazone and zinc chloride at 150—180°. As a by-product, an isomeride of camphorphenylhydrazone,  $C_{16}H_{22}N_2$ , white plates, m. p. 201°, was isolated from the acid solution; it is not identical with the polycamphorphenylhydrazone of Cazeneuve (*Bull. Soc. chim.*, 1889, [iii], 1, 241). **Menthoneindole**,  $C_{16}H_{21}N$ , prepared from menthonephenylhydrazone and zinc chloride at 100°, forms colourless plates, m. p. 106°, b. p. 213°/20 mm. In the reaction there were also formed: aniline, and a base,  $C_{16}H_{23}N$ , a light yellow oil, b. p. 181°/18 mm.; it gives a *N*-benzoyl derivative, colourless prisms, m. p. 163°. K. K.

**The Action of Sodamide on Quinoline.** A. E. TSCHITSCH-BABIN and (Mlle) E. V. ZACEPINA (*J. Russ. Phys. Chem. Soc.*, 1920, 50, 553—557).—The preparation of 2-aminoquinoline by the

action of sodamide on quinoline (A., 1915, i, 591) has been reinvestigated in an endeavour to improve the yield of amino-compound, but without success. The main products of the reaction are *diquinoline*,  $C_{18}H_{14}N_2$ , and *diquinolyl*,  $C_{18}H_{12}N_2$ , the former being extremely readily oxidised to the latter, which is identical with the known 2:3-compound (Weidel, A., 1882, 69).

The following compounds are described: *2-Aminoquinoline*, purified by repeated crystallisation from water or regeneration from the picrate, melts at  $129^\circ$ ; the fractions of lower melting point which are obtained contain a little 4-aminoquinoline (hydrated form, m. p.  $69-70^\circ$ ; anhydrous form, m. p.  $153-154^\circ$ ). The *picrate*, sparingly soluble needles, m. p.  $255-256^\circ$ , and the *hydrochloride*, needles, m. p.  $225-227^\circ$ , were prepared. *Diquinoline* is isolated in the form of its *hydrochloride*, red needles, from hot water, readily oxidising in the air; the *base* obtained from it forms yellow leaflets, m. p.  $185^\circ$ . Thus it is not identical, but isomeric with the compound described by Claus (A., 1882, 215). Its salts with mineral acids have a bright red colour and are sparingly soluble; they are extremely readily oxidised to the colourless, readily soluble, salts of 2:3-diquinolyl which forms leaflets, m. p.  $175^\circ$ .  
G. A. R. K.

**The Action of Sodamide on *iso*Quinoline.** A. E. TSCHITSCHERBIN and (MILLE) M. P. OPARINA (*J. Russ. Phys. Chem. Soc.*, 1920, 50, 543-548).—*iso*Quinoline reacts with sodamide in the presence of neutral solvents in the same way as pyridine and quinoline, an *aminoisoquinoline* being produced; the position taken up by the entering group is between the nitrogen and the benzene nucleus. The new compound, like those previously described, is a mono-acid base; by the action of nitrous acid, it is converted into the known *isocarbostyryl*, thus proving the constitution assigned to it.

*1-Aminoisoquinoline* is obtained in a yield amounting to 38% and forms silvery plates, m. p.  $123^\circ$ . The *picrate* has m. p.  $290-291^\circ$ . The *hydrochloride* forms needles, m. p.  $233-233.5^\circ$ . The *chloroplatinate*, thin, orange needles, does not melt below  $300^\circ$  and crystallises with  $1H_2O$ .

Diazotisation in presence of sulphuric acid leads to the formation of *isocarbostyryl*, almost white needles, m. p.  $206.5-207^\circ$  (cf. Fernau, A., 1893, i, 417); in the presence of hydrochloric acid some 1-chloro*iso*quinoline appears to be produced. G. A. R. K.

**Dihydro*iso*quinoline Derivatives.** M. HARTMANN and H. KAGI (U.S. Pat. 1437802).—Methyl  $\alpha$ -benzamido- $\beta$ -3:4-dimethoxyphenylpropionate, fine needles, m. p.  $104-105^\circ$ , obtained by the hydrogenation of methyl veratrylidenehippurate in methyl-alcoholic solution, when condensed at  $130-135^\circ$  with phosphorus oxychloride, yields methyl 6:7-dimethoxy-1-phenyl-3:4-dihydro*iso*quinoline-3-carboxylate, m. p.  $122.5^\circ$  after recrystallisation from methyl alcohol (*hydrochloride* and *hydrobromide*, yellow crystals). The free ester reacts with methyl iodide to give a 2-methiodide, which is converted by silver chloride into a 2-methochloride. Hydrogenation of methyl piperonylidenehippurate produces methyl

$\alpha$ -benzamido- $\beta$ -piperonylpropionate, brilliant needles, m. p. 126–127°, which on condensation gives methyl 6:7-methylenedioxy-1-phenyl-3:4-dihydroisoquinoline-3-carboxylate, colourless needles, m. p. 140.5°. Methyl  $\alpha$ -piperonylamino- $\beta$ -piperonylpropionate, glassy needles, m. p. 139–140°, yields on condensation methyl 6:7-methylenedioxy-1-mp-methylenedioxyphenyl-3:4-dihydroisoquinoline-3-carboxylate, m. p. 140–141° (hydrochloride, partly decomposed by water). Methyl 6:7-methylenedioxy-1-phenetyl-3:4-dihydroisoquinoline-3-carboxylate, prisms, m. p. 111°, is obtained by condensation of methyl  $\alpha$ -( $\beta$ -phenylpropionylamido)- $\beta$ -piperonylpropionate, m. p. 127°, formed by the hydrogenation of methyl  $\alpha$ -cinnamylamino- $\beta$ -3:4-methylenedioxyphenylacrylate, m. p. 192°. This compound is prepared by heating together equimolecular proportions of piperonal, cinnamylglycine, and sodium acetate and three molecular proportions of acetic anhydride and boiling the product with methyl alcohol and soda. The above compounds have therapeutic properties.

CHEMICAL ABSTRACTS.

**Vapour Pressure of Carbazole.** C. F. SENSEMAN and O. A. NELSON (*Ind. Eng. Chem.*, 1923, 15, 382–383).—A table of the vapour pressures of carbazole between 250° and 355° is given. The determinations were made on carefully purified samples (m. p. 244.8°) (A., 1922, i, 245). Carbazole has b. p. 354.76°, and not 351.5°, as stated in the literature. Interpolation formulæ are derived for the vapour pressures and latent heats of vaporisation:  $\log p = 24.2313 - 4570.3/T - 5.0288 \log T$  and  $L = 22799 - 13.0T$ , respectively. The values given for  $p$  are in good agreement with the observed values.
